Precondition: The value type of *InputIterator* is *std::size_t*. All indices must refer to vertices already added.

<i>Vertex_handle</i>	<i>B.vertex(std::size_t i)</i>	
----------------------	---------------------------------	--

returns handle for the vertex of index *i*, or *Vertex_handle* if there is no *i*-th vertex.

<i>bool</i>	<i>B.error()</i>	returns error status of the builder.
-------------	------------------	--------------------------------------

<i>void</i>	<i>B.rollback()</i>	undoes all changes made to the halfedge data structure since the last <i>begin_surface()</i> in relative indexing, and deletes the whole surface in absolute indexing. It needs a new call to <i>begin_surface()</i> to start inserting again.
-------------	---------------------	--

<i>bool</i>	<i>B.check_unconnected_vertices()</i>	returns <i>true</i> if unconnected vertices are detected. If <i>verbose</i> was set to <i>true</i> (see the constructor above) debug information about the unconnected vertices is printed.
-------------	---------------------------------------	---

<i>bool</i>	<i>B.remove_unconnected_vertices()</i>	returns <i>true</i> if all unconnected vertices could be removed successfully. This happens either if no unconnected vertices had appeared or if the halfedge data structure supports the removal of individual elements.
-------------	--	---

Example

A modifier class creates a new triangle in the halfedge data structure using the incremental builder.

```
#include <CGAL/Simple_cartesian.h>
#include <CGAL/Polyhedron_incremental_builder_3.h>
#include <CGAL/Polyhedron_3.h>

// A modifier creating a triangle with the incremental builder.
template <class HDS>
class Build_triangle : public CGAL::Modifier_base<HDS> {
public:
    Build_triangle() {}
    void operator()( HDS& hds) {
        // Postcondition: 'hds' is a valid polyhedral surface.
        CGAL::Polyhedron_incremental_builder_3<HDS> B( hds, true);
        B.begin_surface( 3, 1, 6);
        typedef typename HDS::Vertex    Vertex;
        typedef typename Vertex::Point Point;
        B.add_vertex( Point( 0, 0, 0));
        B.add_vertex( Point( 1, 0, 0));
        B.add_vertex( Point( 0, 1, 0));
        B.begin_facet();
        B.add_vertex_to_facet( 0);
        B.add_vertex_to_facet( 1);
        B.add_vertex_to_facet( 2);
        B.end_facet();
        B.end_surface();
    }
};

typedef CGAL::Simple_cartesian<double>      Kernel;
typedef CGAL::Polyhedron_3<Kernel>          Polyhedron;
typedef Polyhedron::HalfedgeDS              HalfedgeDS;

int main() {
    Polyhedron P;
    Build_triangle<HalfedgeDS> triangle;
    P.delegate( triangle);
    CGAL_assertion( P.is_triangle( P.halfedges_begin()));
    return 0;
}
```

PolyhedronItems_3

Definition

The `PolyhedronItems_3` concept extends the `HalfedgeDSItems` concept on page 1841. In addition to the requirements stated there, a model for this concept must fulfill the following requirements for the local `PolyhedronItems_3::Vertex_wrapper<Refs,Traits>::Vertex` type and `PolyhedronItems_3::Face_wrapper<Refs,Traits>::Face` type in order to support the point for vertices and the optional plane equation for facets. Note that the items class uses face instead of facet. Only the polyhedral surface renames faces to facets.

Refines

`HalfedgeDSItems` page 1821

Types in `PolyhedronItems_3::Vertex_wrapper<Refs,Traits>::Vertex`

`Vertex::Point` point type stored in vertices. A `HalfedgeDS` has no dimension, so this type is named `Point` and not `Point_3`.

`Vertex::Supports_vertex_point` \equiv `CGAL::Tag_true`. A point is always required.

Operations

<code>Point&</code>	<code>v.point()</code>	
<code>const Point&</code>	<code>v.point() const</code>	point.

Types in `PolyhedronItems_3::Face_wrapper<Refs,Traits>::Face`

Types for (optionally) associated geometry in faces. If it is not supported the respective type has to be defined, although it can be an arbitrary dummy type, such as `void*` or `Tag_false`.

`Face::Plane` plane type stored in faces. A `HalfedgeDS` has no dimension, so this type is named `Plane` and not `Plane_3`.

`Face::Supports_face_plane` either `CGAL::Tag_true` or `CGAL::Tag_false`.

Operations required if `Supports_face_plane \equiv CGAL::Tag_true`

<code>Plane&</code>	<code>f.plane()</code>	
<code>const Plane&</code>	<code>f.plane() const</code>	plane equation.

Example

We define our own items class based on the available *CGAL::HalfedgeDS_face_base* base class for faces. We derive the *Halfedge_wrapper* without further modifications from the *CGAL::HalfedgeDS_items_2*, replace the *Face_wrapper* definition with our new definition, and also replace the *Vertex_wrapper* with a definition that uses *Point_3* instead of *Point_2* as point type. The result is a model for the *PolyhedronItems_3* concept similar to the available *CGAL::Polyhedron_items_3* class. See also there for another illustrative example.

```
#include <CGAL/HalfedgeDS_bases.h>

struct My_items : public CGAL::HalfedgeDS_items_2 {
    template < class Refs, class Traits>
    struct Vertex_wrapper {
        typedef typename Traits::Point_3 Point;
        typedef CGAL::HalfedgeDS_vertex_base< Refs, CGAL::Tag_true,
Point> Vertex;
    };
    template < class Refs, class Traits>
    struct Face_wrapper {
        typedef typename Traits::Plane_3 Plane;
        typedef CGAL::HalfedgeDS_face_base< Refs, CGAL::Tag_true, Plane>
Face;
    };
};
```

CGAL::Polyhedron_items_3

Definition

The class *Polyhedron_items_3* is a model of the *PolyhedronItems_3* concept. It provides definitions for vertices with points, halfedges, and faces with plane equations. The polyhedron traits class must provide the respective types for the point and the plane equation. Vertices and facets both contain a halfedge handle to an incident halfedge.

```
#include <CGAL/Polyhedron_items_3.h>
```

Is Model for the Concepts

PolyhedronItems_3 page [1784](#)

Types in *Polyhedron_items_3::Vertex_wrapper<Refs,Traits>::Vertex*

```
typedef Traits::Point_3      Point;
typedef CGAL::Tag_true      Supports_vertex_point;
```

Types in *Polyhedron_items_3::Face_wrapper<Refs,Traits>::Face*

```
typedef Traits::Plane_3      Plane;
typedef CGAL::Tag_true      Supports_face_plane;
```

Creation

Polyhedron_items_3 items; default constructor.

Operations

Supported as required by the *PolyhedronItems_3* concept.

Example

The following example program defines a new face class based on the *CGAL::HalfedgeDS_face_base* and adds a new color member variable. The new face class is used to replace the face definition in the *CGAL::Polyhedron_items_3* class. The main function illustrates the access to the new member variable. See also the *PolyhedronItems_3* concept for another illustrative example.

```

#include <CGAL/Simple_cartesian.h>
#include <CGAL/IO/Color.h>
#include <CGAL/Polyhedron_3.h>

// A face type with a color member variable.
template <class Refs>
struct My_face : public CGAL::HalfedgeDS_face_base<Refs> {
    CGAL::Color color;
};

// An items type using my face.
struct My_items : public CGAL::Polyhedron_items_3 {
    template <class Refs, class Traits>
    struct Face_wrapper {
        typedef My_face<Refs> Face;
    };
};

typedef CGAL::Simple_cartesian<double>          Kernel;
typedef CGAL::Polyhedron_3<Kernel, My_items>    Polyhedron;
typedef Polyhedron::Halfedge_handle             Halfedge_handle;

int main() {
    Polyhedron P;
    Halfedge_handle h = P.make_tetrahedron();
    h->facet()->color = CGAL::RED;
    return 0;
}

```

File: examples/Polyhedron/polyhedron_prog_color.cpp

CGAL::Polyhedron_min_items_3

Definition

The class *Polyhedron_min_items_3* is a minimal model of the *PolyhedronItems_3* concept. It provides definitions for vertices containing points, halfedges, and faces. The polyhedron traits class must provide the respective type for the point. Vertices and facets both do *not* contain a halfedge handle to an incident halfedge.

```
#include <CGAL/Polyhedron_min_items_3.h>
```

Is Model for the Concepts

PolyhedronItems_3 page [1784](#)

Types in *Polyhedron_min_items_3::Vertex_wrapper<Refs,Traits>::Vertex*

```
typedef Traits::Point_3      Point;
typedef CGAL::Tag_true      Supports_vertex_point;
```

Types in *Polyhedron_min_items_3::Face_wrapper<Refs,Traits>::Face*

```
typedef CGAL::Tag_false      Supports_face_plane;
```

Creation

Polyhedron_min_items_3 items; default constructor.

Operations

Supported as required by the *PolyhedronItems_3* concept.

See Also

CGAL::Polyhedron_3<Traits> page [1761](#)

PolyhedronTraits_3

Required types and member functions for the PolyhedronTraits_3 concept. This geometric traits concept is used in the polyhedral surface data structure *CGAL::Polyhedron_3<Traits>*. This concept is a subset of the 3d kernel traits and any CGAL kernel model can be used directly as template argument.

Refines

CopyConstructable, *Assignable*.

Types

PolyhedronTraits_3::Point_3 point type.

PolyhedronTraits_3::Plane_3 plane equation. Even if plane equations are not supported with a particular polyhedral surface this type has to be defined (some dummy type).

PolyhedronTraits_3::Construct_opposite_plane_3

is an unary function object that reverses the plane orientation. Must provide *Plane_3 operator()(Plane_3 plane)* that returns the reversed plane. Required only if plane equations are supported and the *inside_out()* method is used to reverse the polyhedral surface orientation.

Creation

PolyhedronTraits_3 traits(traits2); copy constructor.

PolyhedronTraits_3& traits = traits2 assignment.

Operations

Construct_opposite_plane_3 traits.construct_opposite_plane_3_object()

returns an instance of this function object.

Has Models

CGAL::Polyhedron_traits_3<Kernel> page 1790

CGAL::Polyhedron_traits_with_normals_3<Kernel> page 1792

All models of the *CGAL::Kernel* concept, e.g., *Simple_cartesian<FieldNumberType>*.

CGAL::Polyhedron_traits_3<Kernel>

Definition

The class *Polyhedron_traits_3<Kernel>* is a model of the *PolyhedronTraits_3* concept. It defines the geometric types and primitive operations used in the polyhedral surface data structure *CGAL::Polyhedron_3<PolyhedronTraits_3>* in terms of the CGAL *Kernel*. It keeps a local copy of the kernel which makes it suitable for kernels with local state.

```
#include <CGAL/Polyhedron_traits_3.h>
```

Is Model for the Concepts

PolyhedronTraits_3 page [1789](#)

Types

<i>Polyhedron_traits_3<Kernel>::Kernel</i>	the <i>Kernel</i> model.
<i>typedef Kernel::Point_3</i>	<i>Point_3</i> ;
<i>typedef Kernel::Plane_3</i>	<i>Plane_3</i> ;
<i>typedef Kernel::Construct_opposite_plane_3</i>	<i>Construct_opposite_plane_3</i> ;

Creation

<i>Polyhedron_traits_3<Kernel> traits;</i>	default constructor, uses <i>Kernel()</i> as local reference to the kernel.
--	---

<i>Polyhedron_traits_3<Kernel> traits(Kernel kernel);</i>	stores <i>kernel</i> as local reference.
--	--

Operations

<i>Construct_opposite_plane_3 traits.construct_opposite_plane_3_object()</i>	forwarded to <i>kernel</i> .
--	------------------------------

See Also

CGAL::Polyhedron_traits_with_normals_3<Kernel> page [1792](#)

Implementation

Since the *PolyhedronTraits_3* concept is a subset of the 3D kernel concept, this class just forwards the relevant types and access member functions from its template argument. However, it is useful for testing sufficiency of requirements.

Example

Instantiation of a polyhedral surface with the Cartesian kernel based on double coordinates.

```

#include <CGAL/Simple_cartesian.h>
#include <CGAL/Polyhedron_3.h>

typedef CGAL::Simple_cartesian<double>      Kernel;
typedef CGAL::Polyhedron_3<Kernel>         Polyhedron;
typedef Polyhedron::Halfedge_handle        Halfedge_handle;

int main() {
    Polyhedron P;
    Halfedge_handle h = P.make_tetrahedron();
    if ( P.is_tetrahedron(h) )
        return 0;
    return 1;
}

```

File: examples/Polyhedron/polyhedron_prog_simple.cpp

CGAL::Polyhedron_traits_with_normals_3<Kernel>

Definition

The class *Polyhedron_traits_with_normals_3<Kernel>* is a model of the *PolyhedronTraits_3* concept. It defines the geometric types and primitive operations used in the polyhedral surface data structure *CGAL::Polyhedron_3<PolyhedronTraits_3>*. *Polyhedron_traits_with_normals_3<Kernel>* uses the normal vector from *Kernel* for the plane equation in facets. It keeps a local copy of the kernel which makes it suitable for kernels with local state.

```
#include <CGAL/Polyhedron_traits_with_normals_3.h>
```

Is Model for the Concepts

PolyhedronTraits_3 page [1789](#)

Types

```
Polyhedron_traits_with_normals_3<Kernel>::Kernel           the Kernel model.  
typedef Kernel::Point_3                                   Point_3;  
typedef Kernel::Vector_3                                  Plane_3;
```

```
typedef Kernel::Construct_opposite_vector_3    Construct_opposite_plane_3;
```

Creation

```
Polyhedron_traits_with_normals_3<Kernel> traits;           default constructor, uses Kernel() as  
local reference to the kernel.
```

```
Polyhedron_traits_with_normals_3<Kernel> traits( Kernel kernel);    stores kernel as local reference.
```

Operations

```
Construct_opposite_plane_3           traits.construct_opposite_plane_3_object()  
forwarded to kernel.
```

See Also

CGAL::Polyhedron_traits_3<Kernel> page [1790](#)

Example

We use this traits class to instantiate a polyhedral surface with a normal vector and no plane equation for each facet. We compute the normal vector assuming exact arithmetic (integers in this example) and convex planar facets.

```

#include <CGAL/Homogeneous.h>
#include <CGAL/Polyhedron_traits_with_normals_3.h>
#include <CGAL/Polyhedron_3.h>
#include <iostream>
#include <algorithm>

struct Normal_vector {
    template <class Facet>
    typename Facet::Plane_3 operator()( Facet& f) {
        typename Facet::Halfedge_handle h = f.halfedge();
        // Facet::Plane_3 is the normal vector type. We assume the
        // CGAL Kernel here and use its global functions.
        return CGAL::cross_product(
            h->next()->vertex()->point() - h->vertex()->point(),
            h->next()->next()->vertex()->point() -
            h->next()->vertex()->point());
    }
};

typedef CGAL::Homogeneous<int> Kernel;
typedef Kernel::Point_3 Point_3;
typedef Kernel::Vector_3 Vector_3;
typedef CGAL::Polyhedron_traits_with_normals_3<Kernel> Traits;
typedef CGAL::Polyhedron_3<Traits> Polyhedron;

int main() {
    Point_3 p( 1, 0, 0);
    Point_3 q( 0, 1, 0);
    Point_3 r( 0, 0, 1);
    Point_3 s( 0, 0, 0);
    Polyhedron P;
    P.make_tetrahedron( p, q, r, s);
    std::transform( P.facets_begin(), P.facets_end(), P.planes_begin(),
                    Normal_vector());
    CGAL::set_pretty_mode( std::cout);
    std::copy( P.planes_begin(), P.planes_end(),
               std::ostream_iterator<Vector_3>( std::cout, "\n"));
    return 0;
}

```

File: examples/Polyhedron/polyhedron_prog_normals.cpp

CGAL::operator<<

Definition

This operator writes the polyhedral surface P to the output stream out using the Object File Format, OFF, with file extension `.off`, which is also understood by GeomView [\[Phi96\]](#). The output is in ASCII format. From the polyhedral surface, only the point coordinates and facets are written. Neither normal vectors nor color attributes are used.

For OFF an ASCII and a binary format exist. The format can be selected with the CGAL modifiers for streams, `set_ascii_mode` and `set_binary_mode` respectively. The modifier `set_pretty_mode` can be used to allow for (a few) structuring comments in the output. Otherwise, the output would be free of comments. The default for writing is ASCII without comments.

```
#include <CGAL/IO/Polyhedron_iostream.h>
```

```
template <class PolyhedronTraits_3>
ostream& ostream& out << CGAL::Polyhedron_3<PolyhedronTraits_3> P
```

See Also

`CGAL::Polyhedron_3<Traits>` [page 1761](#)
`operator>>` [page 1795](#)

CGAL::operator>>

Definition

This operator reads a polyhedral surface in Object File Format, OFF, with file extension `.off`, which is also understood by Geomview [Phi96], from the input stream *in* and appends it to the polyhedral surface *P*. Only the point coordinates and facets from the input stream are used to build the polyhedral surface. Neither normal vectors nor color attributes are evaluated. If the stream *in* does not contain a permissible polyhedral surface the `ios::badbit` of the input stream *in* is set and *P* remains unchanged.

For OFF an ASCII and a binary format exist. The stream detects the format automatically and can read both.

```
#include <CGAL/IO/Polyhedron_iostream.h>
```

```
template <class PolyhedronTraits_3>
istream& istream& in >> CGAL::Polyhedron_3<PolyhedronTraits_3>& P
```

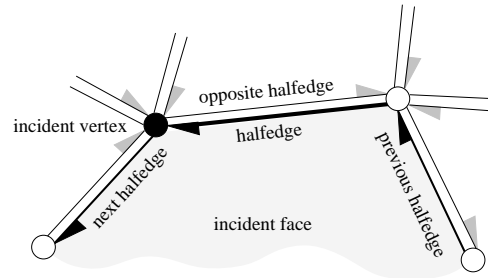

See Also

`CGAL::Polyhedron_3<Traits>` page 1761
`CGAL::Polyhedron_incremental_builder_3<HDS>` page 1780
`operator<<` page 1794

Implementation

This operator is implemented using the modifier mechanism for polyhedral surfaces and the `CGAL::Polyhedron_incremental_builder_3` class, which allows the construction in a single, efficient scan pass of the input and handles also all the possible flexibility of the polyhedral surface.

26.1 Introduction

A halfedge data structure (abbreviated as *HalfedgeDS*, or *HDS* for template parameters) is an edge-centered data structure capable of maintaining incidence information of vertices, edges and faces, for example for planar maps, polyhedra, or other orientable, two-dimensional surfaces embedded in arbitrary dimension. Each edge is decomposed into two halfedges with opposite orientations. One incident face and one incident vertex are stored in each halfedge. For each face and each vertex, one incident halfedge is stored. Reduced variants of the halfedge data structure can omit some of these information, for example the halfedge pointers in faces or the storage of faces at all.

The halfedge data structure is a combinatorial data structure, geometric interpretation is added by classes built on top of the halfedge data structure. These classes might be more convenient to use than the halfedge data structure directly, since the halfedge data structure is meant as an implementation layer. See for example the *CGAL::Polyhedron_3* class in Chapter 25.

The data structure provided here is also known as the FE-structure [Wei85], as halfedges [Män88, BFH95] or as the doubly connected edge list (DCEL) [dBvKOS97], although the original reference for the DCEL [MP78]

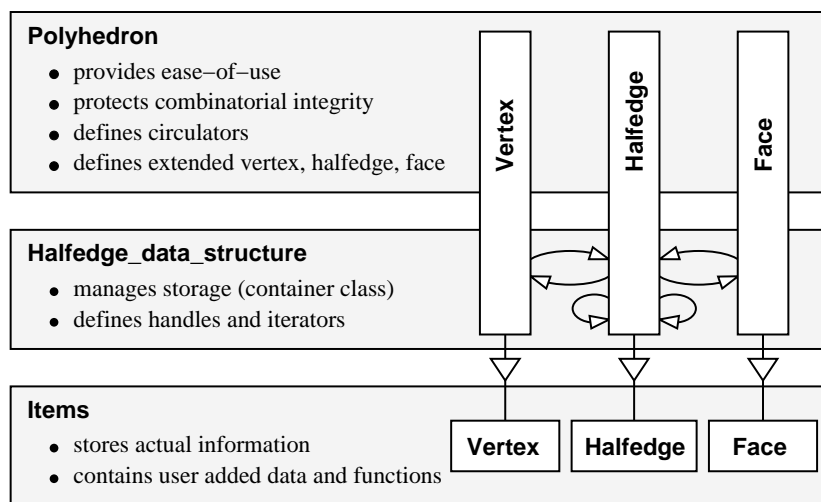

Figure 26.1: Responsibilities of the different layers in the halfedge data-structure design.

describes a different data structure. The halfedge data structure can also be seen as one of the variants of the quad-edge data structure [GS85]. In general, the quad-edge data can represent non-orientable 2-manifolds, but the variant here is restricted to orientable 2-manifolds only. An overview and comparison of these different data structures together with a thorough description of the design implemented here can be found in [Ket99].

The design presented here is a revised and incompatible version of the previous design [Ket98] as used in CGAL R2.2 and earlier releases. Files and identifier names are disjoint with the old design which allows for both versions to co-exists. However, classes using a halfedge data structure can only use one design. For example the polyhedral surface *Polyhedron_3* uses by default the new design. See Chapter 25 for how to still select the old implementation.

26.2 Software Design

Figure 26.1 illustrates the responsibilities of the three layers of the software design, with the *CGAL::Polyhedron_3* as an example for the top layer. The items provide the space for the information that is actually stored, i.e., with member variables and access member functions in *Vertex*, *Halfedge*, and *Face* respectively. Halfedges are required to provide a reference to the next halfedge and to the opposite halfedge. Optionally they may provide a reference to the previous halfedge, to the incident vertex, and to the incident face. Vertices and faces may be empty. Optionally they may provide a reference to the incident halfedge. The options mentioned are supported in the halfedge data structure and the polyhedron, for example, Euler operations update the optional references if they are present. Furthermore, the item classes can be extended with arbitrary attributes and member functions, which will be promoted by inheritance to the actual classes used for the polyhedron.

Vertices, halfedges, and faces are passed as local types of the *Items* class to the halfedge data structure and polyhedron. Implementations for vertices, halfedges and faces are provided that fulfill the mandatory part of the requirements. They can be used as base classes for extensions by the user. Richer implementations are also provided to serve as defaults; for polyhedra they provide all optional incidences, a three-dimensional point in the vertex type and a plane equation in the face type.

The *Halfedge_data_structure*, concept *HalfedgeDS*, is responsible for the storage organization of the items. Currently, implementations using internally a bidirectional list or a vector are provided. The *HalfedgeDS* defines

the handles and iterators belonging to the items. These types are promoted to the declaration of the items themselves and are used there to provide the references to the incident items. This promotion of types is done with a template parameter *Refs* of the item types. The halfedge data structure provides member functions to insert and delete items, to traverse all items, and it gives access to the items.

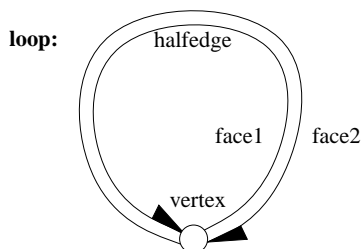

There are two different models for the *HalfedgeDS* concept available, *HalfedgeDS_list* and *HalfedgeDS_vector*, and more might come. Therefore we have kept their interface small and factored out common functionality into separate helper classes, *HalfedgeDS_decorator*, *HalfedgeDS_const_decorator*, and *HalfedgeDS_items_decorator*, which are not shown in Figure 26.1, but would be placed at the side of the *HalfedgeDS* since they broaden that interface but do not hide it. These helper classes contain operations that are useful to implement the operations in the next layer, for example, the polyhedron. They add, for example, the Euler operations and partial operations from which further Euler operations can be built, such as inserting an edge into the ring of edges at a vertex. Furthermore, the helper classes contain adaptive functionality. For example, if the *prev()* member function is not provided for halfedges, the *find_prev()* member function of a helper class searches in the positive direction along the face for the previous halfedge. But if the *prev()* member function is provided, the *find_prev()* member function simply calls it. This distinction is resolved at compile time with a technique called *compile-time tags*, similar to iterator tags in [SL95].

The *Polyhedron_3* as an example for the third layer adds the geometric interpretation, provides an easy-to-use interface of high-level functions, and unifies the access to the flexibility provided underneath. It renames face to facet, which is more common for three-dimensional surfaces. The interface is designed to protect the integrity of the internal representation, the handles stored in the items can no longer directly be written by the user. The polyhedron adds the convenient and efficient circulators, see *Circulator*, for accessing the circular sequence of edges around a vertex or around a facet. To achieve this, the *Polyhedron_3* derives new vertices, halfedges and facets from those provided in *Items*. These new items are those actually used in the *HalfedgeDS*, which gives us the coherent type structure in this design, especially if compared to our previous design.

26.3 Example Programs

26.3.1 The Default Halfedge Data Structure

The following example program uses the default halfedge data structure and the decorator class. The default halfedge data structure uses a list-based representation. All incidences of the items and a point type for vertices are defined. The trivial traits class provides the type used for the point. The program creates a loop, consisting of two halfedges, one vertex and two faces, and checks its validity.

```
#include <CGAL/HalfedgeDS_default.h>
#include <CGAL/HalfedgeDS_decorator.h>

struct Traits { typedef int Point_2; };
typedef CGAL::HalfedgeDS_default<Traits> HDS;
typedef CGAL::HalfedgeDS_decorator<HDS> Decorator;
```

```

int main() {
    HDS hds;
    Decorator decorator(hds);
    decorator.create_loop();
    CGAL_assertion( decorator.is_valid());
    return 0;
}

```

File: examples/HalfedgeDS/hds_prog_default.cpp

26.3.2 A Minimal Halfedge Data Structure

The following program defines a minimal halfedge data structure using the minimal items class `CGAL::HalfedgeDS_min_items` and a list-based halfedge data structure. The result is a data structure maintaining only halfedges with next and opposite pointers. No vertices or faces are stored. The data structure represents an *undirected graph*.

```

#include <CGAL/HalfedgeDS_min_items.h>
#include <CGAL/HalfedgeDS_default.h>
#include <CGAL/HalfedgeDS_decorator.h>

// no traits needed, argument can be arbitrary dummy.
typedef CGAL::HalfedgeDS_default<int, CGAL::HalfedgeDS_min_items> HDS;
typedef CGAL::HalfedgeDS_decorator<HDS> Decorator;

int main() {
    HDS hds;
    Decorator decorator(hds);
    decorator.create_loop();
    CGAL_assertion( decorator.is_valid());
    return 0;
}

```

File: examples/HalfedgeDS/hds_prog_graph.cpp

26.3.3 The Default with a Vector Instead of a List

The default halfedge data structure uses a list internally and the maximal base classes. We change the list to a vector representation here. Again, a trivial traits class provides the type used for the point. Note that for the vector storage the size of the halfedge data structure should be reserved beforehand, either with the constructor as shown in the example or with the `reserve()` member function. One can later resize the data structure with further calls to the `reserve()` member function, but only if the data structure is in a consistent, i.e., *valid*, state.

Unfortunately this example has also to expose the workaround necessary for compilers that do not support templates as template parameters. The workaround is necessary if the symbolic constant `CGAL_CFG_NO_TMPL_IN_TMPL_PARAM` is set. It uses a member template instead of the class template.

```

#include <CGAL/HalfedgeDS_items_2.h>
#include <CGAL/HalfedgeDS_vector.h>

```

```

#include <CGAL/HalfedgeDS_decorator.h>

struct Traits { typedef int Point_2; };
typedef CGAL::HalfedgeDS_vector< Traits, CGAL::HalfedgeDS_items_2> HDS;
typedef CGAL::HalfedgeDS_decorator<HDS> Decorator;

int main() {
    HDS hds(1,2,2);
    Decorator decorator(hds);
    decorator.create_loop();
    CGAL_assertion( decorator.is_valid());
    return 0;
}

```

File: examples/HalfedgeDS/hds_prog_vector.cpp

26.3.4 Example Adding Color to Faces

This example re-uses the base class available for faces and adds a member variable *color*.

```

#include <CGAL/HalfedgeDS_items_2.h>
#include <CGAL/HalfedgeDS_default.h>
#include <CGAL/IO/Color.h>

// A face type with a color member variable.
template <class Refs>
struct My_face : public CGAL::HalfedgeDS_face_base<Refs> {
    CGAL::Color color;
    My_face() {}
    My_face( CGAL::Color c) : color(c) {}
};

// An items type using my face.
struct My_items : public CGAL::HalfedgeDS_items_2 {
    template <class Refs, class Traits>
    struct Face_wrapper {
        typedef My_face<Refs> Face;
    };
};

struct My_traits { // arbitrary point type, not used here.
    typedef int Point_2;
};

typedef CGAL::HalfedgeDS_default<My_traits, My_items> HDS;
typedef HDS::Face Face;
typedef HDS::Face_handle Face_handle;

int main() {
    HDS hds;
    Face_handle f = hds.faces_push_back( Face( CGAL::RED));
    f->color = CGAL::BLUE;
}

```

```

    CGAL_assertion( f->color == CGAL::BLUE);
    return 0;
}

```

File: examples/HalfedgeDS/hds_prog_color.cpp

26.3.5 Example Defining a More Compact Halfedge

—advanced—

The halfedge data structure as presented here is slightly less space efficient as, for example, the winged-edge data structure [Bau75], the DCEL [MP78] or variants of the quad-edge data structure [GS85]. On the other hand, it does not require any search operations during traversals. A comparison can be found in [Ket99].

The following example trades traversal time for a compact storage representation using traditional C techniques (i.e., type casting and the assumption that pointers, especially those from `malloc` or `new`, point to even addresses). The idea goes as follows: The halfedge data structure allocates halfedges pairwise. Concerning the vector-based data structure this implies that the absolute value of the difference between a halfedge and its opposite halfedge is always one with respect to C pointer arithmetic. We can replace the opposite pointer by a single bit encoding the sign of this difference. We will store this bit as the least significant bit in the next halfedge handle. Furthermore, we do not implement a pointer to the previous halfedge. What remains are three pointers per halfedge.

We use the static member function `halfedge_handle()` to convert from pointers to halfedge handles. The same solution can be applied to the list-based halfedge data structure `CGAL::HalfedgeDS_list`, see examples/HalfedgeDS/hds_prog_compact2.cpp. Here is the example for the vector-based data structure.

```

#include <CGAL/HalfedgeDS_items_2.h>
#include <CGAL/HalfedgeDS_vector.h>
#include <CGAL/HalfedgeDS_decorator.h>
#include <cstdint>

// Define a new halfedge class. We assume that the Halfedge_handle can
// be created from a pointer (e.g. the HalfedgeDS is based here on the
// In_place_list or a std::vector with such property) and that halfedges
// are allocated in pairs. We encode the opposite pointer in a single
// bit,
// which is stored in the lower bit of the next-pointer. We use the
// static member function HDS::halfedge_handle to translate pointer to
// handles.
template <class Refs>
class My_halfedge {
public:
    typedef Refs                                HDS;
    typedef My_halfedge<Refs>                   Base_base;
    typedef My_halfedge<Refs>                   Base;
    typedef My_halfedge<Refs>                   Self;
    typedef CGAL::Tag_false                     Supports_halfedge_prev;
    typedef CGAL::Tag_true                      Supports_halfedge_vertex;
    typedef CGAL::Tag_true                      Supports_halfedge_face;
    typedef typename Refs::Vertex_handle       Vertex_handle;

```

```

typedef typename Refs::Vertex_const_handle    Vertex_const_handle;
typedef typename Refs::Halfedge              Halfedge;
typedef typename Refs::Halfedge_handle       Halfedge_handle;
typedef typename Refs::Halfedge_const_handle Halfedge_const_handle;

26.3.6 Example Using the Halfedge Iterator

Two edges are created in the default halfedge data structure. The halfedge iterator is used to count the halfedges.

```

#include <CGAL/HalfedgeDS_default.h>
#include <CGAL/HalfedgeDS_decorator.h>

struct Traits { typedef int Point_2; };
typedef CGAL::HalfedgeDS_default<Traits> HDS;
typedef CGAL::HalfedgeDS_decorator<HDS> Decorator;
typedef HDS::Halfedge_iterator           Iterator;

int main() {
    HDS hds;
    Decorator decorator(hds);
    decorator.create_loop();
    decorator.create_segment();
}

```

```

    CGAL_assertion( decorator.is_valid());
    int n = 0;
    for ( Iterator i = hds.halfedges_begin(); i != hds.halfedges_end();
        ++i )
        ++n;
    CGAL_assertion( n == 4); // == 2 edges
    return 0;
}

```

File: examples/HalfedgeDS/hds_prog_halfedge_iterator.cpp

26.3.7 Example for an Adapter to Build an Edge Iterator

Three edges are created in the default halfedge data structure. The adapter *N_step_adaptor* is used to declare the edge iterator used in counting the edges.

```

#include <CGAL/HalfedgeDS_default.h>
#include <CGAL/HalfedgeDS_decorator.h>
#include <CGAL/N_step_adaptor.h>

struct Traits { typedef int Point_2; };
typedef CGAL::HalfedgeDS_default<Traits>          HDS;
typedef CGAL::HalfedgeDS_decorator<HDS>          Decorator;
typedef HDS::Halfedge_iterator                   Halfedge_iterator;
typedef CGAL::N_step_adaptor< Halfedge_iterator, 2> Iterator;

int main() {
    HDS hds;
    Decorator decorator(hds);
    decorator.create_loop();
    decorator.create_segment();
    CGAL_assertion( decorator.is_valid());
    int n = 0;
    for ( Iterator e = hds.halfedges_begin(); e != hds.halfedges_end();
        ++e)
        ++n;
    CGAL_assertion( n == 2); // == 2 edges
    return 0;
}

```

Halfedge Data Structure

Reference Manual

Lutz Kettner

A halfedge data structure (abbreviated as *HalfedgeDS*, or *HDS* for template parameters) is an edge-centered data structure capable of maintaining incidence information of vertices, edges and faces, for example for planar maps or polyhedral surfaces. It is a combinatorial data structure, geometric interpretation is added by classes built on top of the halfedge data structure. These classes might be more convenient to use than the halfedge data structure directly, since the halfedge data structure is meant as an implementation layer. See for example the *CGAL::Polyhedron_3* class in Chapter 25.6.2.

The data structure provided here is known as the FE-structure [Wei85], as halfedges [Män88, BFH95] or as the doubly connected edge list (DCEL) [dBvKOS97], although the original reference for the DCEL [MP78] describes a related but different data structure. The halfedge data structure can also be seen as one of the variants of the quad-edge data structure [GS85]. In general, the quad-edge data can represent non-orientable 2-manifolds, but the variant here is restricted to orientable 2-manifolds only. An overview and comparison of these different data structures together with a thorough description of the design implemented here can be found in [Ket99].

HalfedgeDS<Traits,Items,Alloc>

Release Note

Beginning with CGAL R2.3, this package has a new design. The old design is still available for backwards compatibility and to support older compiler, such as MSVC++6.0. However its use is deprecated and the manual pages are not converted into this new manual format. Instead, see its old documentation in the manual of deprecated packages. The two designs are not interchangeable.

Definition

The concept of a halfedge data structure (abbreviated as *HalfedgeDS*, or *HDS* for template parameters) defines an edge-centered data structure capable of maintaining incidence information of vertices, edges, and faces, for example for planar maps or polyhedral surfaces. It is a combinatorial data structure, geometric interpretation is added by classes built on top of the halfedge data structure.

The data structure defined here is known as the FE-structure [Wei85], as halfedges [Män88, BFH95] or as the doubly connected edge list (DCEL) [dBvKOS97], although the original reference for the DCEL [MP78] describes a different data structure. The halfedge data structure can also be seen as one of the variants of the quad-edge data structure [GS85]. In general, the quad-edge data can represent non-orientable 2-manifolds, but the variant here is restricted to orientable 2-manifolds only. An overview and comparison of these different data structures together with a thorough description of the design implemented here can be found in [Ket99].

Each edge is represented by two halfedges with opposite orientations. Each halfedge can store a reference to an incident face and an incident vertex. For each face and each vertex an incident halfedge is stored. Reduced variants of the halfedge data structure can omit some of these incidences, for example the reference to halfedges in vertices or the storage of vertices at all. See Figure 26.2 for the incidences, the mandatory and optional member functions possible for vertices, halfedges, and faces.

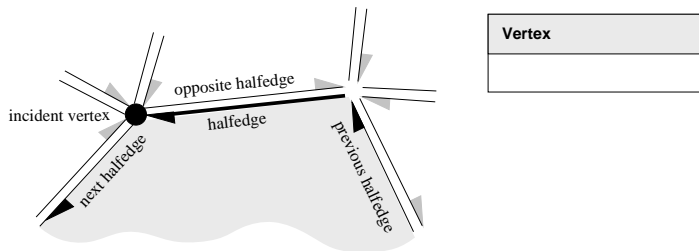

Figure 26.2: The three classes *Vertex*, *Halfedge*, and *Face* of the halfedge data structure. Member functions with shaded background are mandatory. The others are optionally supported.

A `HalfedgeDS<Traits,Items,Alloc>` organizes the internal storage of its items. Examples are a list-based or a vector-based storage. The `HalfedgeDS<Traits,Items,Alloc>` exhibits most of the characteristics of the container class used internally, for example the iterator category. A vector resizes automatically when a new item exceeds the reserved space. Since resizing is an expensive operation for a `HalfedgeDS<Traits,Items,Alloc>` in general and only possible in a well defined state of the data structure (no dangling handles), it must be called explicitly in advance for a `HalfedgeDS<Traits,Items,Alloc>` before inserting new items beyond the current capacity. Classes built on top of a `HalfedgeDS<Traits,Items,Alloc>` are advised to call the `reserve()` member function before creating new items.

Parameters

A `HalfedgeDS<Traits,Items,Alloc>` is a class template and will be used as argument for other class templates, for example `CGAL::Polyhedron_3`. The template parameters to instantiate the `HalfedgeDS<Traits,Items,Alloc>` will be provided by this other class template. Therefore, the three template parameters and their meaning are mandatory. We distinguish between the template `HalfedgeDS<Traits,Items,Alloc>` and an instantiation of it.

Traits is a traits class that will be passed to the item types in *Items*. It will not be used in `HalfedgeDS<Traits,Items,Alloc>` itself. *Items* is a model of the *HalfedgeDSItems* concept. *Alloc* is a standard allocator that fulfills all requirements of allocators for STL container classes. The *rebind* mechanism from *Alloc* will be used to create appropriate allocators internally. A default argument is mandatory for *Alloc*, for example, the macro `CGAL_ALLOCATOR(int)` from the `<CGAL/memory.h>` header file can be used as default allocator.

Types

<code>HalfedgeDS<Traits,Items,Alloc>:: Traits</code>	traits class.
<code>HalfedgeDS<Traits,Items,Alloc>:: Items</code>	model of <i>HalfedgeDSItems</i> concept.

<code>HalfedgeDS<Traits,Items,Alloc>:: size_type</code>	size type.
<code>HalfedgeDS<Traits,Items,Alloc>:: difference_type</code>	difference type.
<code>HalfedgeDS<Traits,Items,Alloc>:: iterator_category</code>	iterator category for all iterators.
<code>HalfedgeDS<Traits,Items,Alloc>:: allocator_type</code>	allocator type <i>Alloc</i> .

<code>HalfedgeDS<Traits,Items,Alloc>:: Vertex</code>	model of <i>HalfedgeDSVertex</i> concept.
<code>HalfedgeDS<Traits,Items,Alloc>:: Halfedge</code>	model of <i>HalfedgeDSHalfedge</i> concept.
<code>HalfedgeDS<Traits,Items,Alloc>:: Face</code>	model of <i>HalfedgeDSFace</i> concept.

The following handles and iterators have appropriate non-mutable counterparts, i.e., *const_handle* and *const_iterator*. The mutable types are assignable to their non-mutable counterparts. The iterators are assignable to the respective handle types. Wherever the handles appear in function parameter lists, the corresponding iterators can be used as well. **Note:** The handle types must have a default constructor that creates a unique and always the same handle value. It will be used in analogy to `NULL` for pointers.

<code>HalfedgeDS<Traits,Items,Alloc>:: Vertex_handle</code>	handle to vertex.
<code>HalfedgeDS<Traits,Items,Alloc>:: Halfedge_handle</code>	handle to halfedge.
<code>HalfedgeDS<Traits,Items,Alloc>:: Face_handle</code>	handle to face.

<code>HalfedgeDS<Traits,Items,Alloc>:: Vertex_iterator</code>	iterator over all vertices.
<code>HalfedgeDS<Traits,Items,Alloc>:: Halfedge_iterator</code>	iterator over all halfedges.
<code>HalfedgeDS<Traits,Items,Alloc>:: Face_iterator</code>	iterator over all faces.

— advanced —

Types for Tagging Optional Features

The following types are equal to either `CGAL::Tag_true` or `CGAL::Tag_false`, depending on whether the named feature is supported or not.

<i>HalfedgeDS</i> < <i>Traits</i> , <i>Items</i> , <i>Alloc</i> >:: <i>Supports_vertex_halfedge</i>	<i>Vertex</i> :: <i>halfedge</i> ()
<i>HalfedgeDS</i> < <i>Traits</i> , <i>Items</i> , <i>Alloc</i> >:: <i>Supports_halfedge_prev</i>	<i>Halfedge</i> :: <i>prev</i> ()
<i>HalfedgeDS</i> < <i>Traits</i> , <i>Items</i> , <i>Alloc</i> >:: <i>Supports_halfedge_vertex</i>	<i>Halfedge</i> :: <i>vertex</i> ()
<i>HalfedgeDS</i> < <i>Traits</i> , <i>Items</i> , <i>Alloc</i> >:: <i>Supports_halfedge_face</i>	<i>Halfedge</i> :: <i>face</i> ()
<i>HalfedgeDS</i> < <i>Traits</i> , <i>Items</i> , <i>Alloc</i> >:: <i>Supports_face_halfedge</i>	<i>Face</i> :: <i>halfedge</i> ()
<i>HalfedgeDS</i> < <i>Traits</i> , <i>Items</i> , <i>Alloc</i> >:: <i>Supports_removal</i>	removal of individual elements.

The following dependencies among these options must be regarded:

Vertices are supported \iff *Supports_halfedge_vertex* \equiv *CGAL::Tag_true*.
 Faces are supported \iff *Supports_halfedge_face* \equiv *CGAL::Tag_true*.
Supports_halfedge \equiv *CGAL::Tag_true* \implies *Supports_halfedge_vertex* \equiv *CGAL::Tag_true*.
Supports_vertex_point \equiv *CGAL::Tag_true* \implies *Supports_halfedge_vertex* \equiv *CGAL::Tag_true*.
Supports_face_halfedge \equiv *CGAL::Tag_true* \implies *Supports_halfedge_face* \equiv *CGAL::Tag_true*.

Static Member Functions

When writing an items type, such as a user defined vertex, certain functions need to create a handle but knowing only a pointer, for example, the *this*-pointer. The following static member functions of *HalfedgeDS*<*Traits*,*Items*,*Alloc*> create such a corresponding handle for an item type from a pointer. This conversion encapsulates possible adjustments for hidden data members in the true item type, such as linked-list pointers. Note that the user provides item types with the *Items* template argument, which may differ from the *Vertex*, *Halfedge*, and *Face* types defined in *HalfedgeDS*<*Traits*,*Items*,*Alloc*>. If they differ, they are derived from the user provided item types. We denote the user item types with *Vertex_base*, *Halfedge_base*, and *Face_base* in the following. The fully qualified name for *Vertex_base* would be for example – assuming that the type *Self* refers to the instantiated *HalfedgeDS* –

```
typedef typename Items::template Vertex_wrapper<Self,Traits> Vertex_wrapper;
typedef typename Vertex_wrapper::Vertex Vertex_base;
```

Implementing these functions relies on the fundamental assumption that an iterator (or handle) of the internally used container class can be constructed from a pointer of a contained item only. This is true and controlled by us for *CGAL::In_place_list*. It is true for the *std::vector* of major STL distributions, but not necessarily guaranteed. We might switch to an internal implementation if need arises.

<i>static Vertex_handle</i>	<i>HalfedgeDS</i> :: <i>vertex_handle</i> (<i>Vertex_base</i> * <i>v</i>)
<i>static Vertex_const_handle</i>	<i>HalfedgeDS</i> :: <i>vertex_handle</i> (<i>const Vertex_base</i> * <i>v</i>)
<i>static Halfedge_handle</i>	<i>HalfedgeDS</i> :: <i>halfedge_handle</i> (<i>Halfedge_base</i> * <i>h</i>)
<i>static Halfedge_const_handle</i>	<i>HalfedgeDS</i> :: <i>halfedge_handle</i> (<i>const Halfedge_base</i> * <i>h</i>)
<i>static Face_handle</i>	<i>HalfedgeDS</i> :: <i>face_handle</i> (<i>Face_base</i> * <i>f</i>)
<i>static Face_const_handle</i>	<i>HalfedgeDS</i> :: <i>face_handle</i> (<i>const Face_base</i> * <i>f</i>)

— advanced —

Creation

<i>HalfedgeDS</i> < <i>Traits</i> , <i>Items</i> , <i>Alloc</i> > <i>hds</i> ;	empty halfedge data structure.
<i>HalfedgeDS</i> < <i>Traits</i> , <i>Items</i> , <i>Alloc</i> > <i>hds</i> (<i>size_type</i> <i>v</i> , <i>size_type</i> <i>h</i> , <i>size_type</i> <i>f</i>);	storage reserved for <i>v</i> vertices, <i>h</i> halfedges, and <i>f</i> faces.
<i>HalfedgeDS</i> < <i>Traits</i> , <i>Items</i> , <i>Alloc</i> > <i>hds</i> (<i>hds2</i>);	copy constructor. <i>Precondition</i> : <i>hds2</i> contains no dangling handles.
<i>HalfedgeDS</i> < <i>Traits</i> , <i>Items</i> , <i>Alloc</i> >& <i>hds</i> = <i>hds2</i>	assignment operator. <i>Precondition</i> : <i>hds2</i> contains no dangling handles.
<i>void</i> <i>hds.reserve</i> (<i>size_type</i> <i>v</i> , <i>size_type</i> <i>h</i> , <i>size_type</i> <i>f</i>)	reserves storage for <i>v</i> vertices, <i>h</i> halfedges, and <i>f</i> faces. If all capacities are already greater or equal than the requested sizes nothing happens. Otherwise, <i>hds</i> will be resized and all handles, iterators and circulators invalidate. <i>Precondition</i> : If resizing is necessary <i>hds</i> contains no dangling handles.

Access Member Functions

<i>Size</i>	<i>hds.size_of_vertices</i> ()	number of vertices.
<i>Size</i>	<i>hds.size_of_halfedges</i> ()	number of halfedges.
<i>Size</i>	<i>hds.size_of_faces</i> ()	number of faces.
<i>Size</i>	<i>hds.capacity_of_vertices</i> ()	space reserved for vertices.
<i>Size</i>	<i>hds.capacity_of_halfedges</i> ()	space reserved for halfedges.
<i>Size</i>	<i>hds.capacity_of_faces</i> ()	space reserved for faces.
<i>size_t</i>	<i>hds.bytes</i> ()	bytes used for <i>hds</i> .
<i>size_t</i>	<i>hds.bytes_reserved</i> ()	bytes reserved for <i>hds</i> .
<i>allocator_type</i>	<i>hds.get_allocator</i> ()	allocator object.

The following member functions return the non-mutable iterator if *hds* is declared const.

<i>Vertex_iterator</i>	<i>hds.vertices_begin</i> ()	iterator over all vertices.
<i>Vertex_iterator</i>	<i>hds.vertices_end</i> ()	
<i>Halfedge_iterator</i>	<i>hds.halfedges_begin</i> ()	iterator over all halfedges
<i>Halfedge_iterator</i>	<i>hds.halfedges_end</i> ()	
<i>Face_iterator</i>	<i>hds.faces_begin</i> ()	iterator over all faces.
<i>Face_iterator</i>	<i>hds.faces_end</i> ()	

Insertion

Note that the vertex-related and the face-related member functions may not be provided for a *HalfedgeDS*<*Traits*,*Items*,*Alloc*> that does not support vertices or faces respectively.

Vertex_handle *hds.vertices_push_back(const Vertex& v)*

appends a copy of *v* to *hds*. Returns a handle of the new vertex.

Halfedge_handle *hds.edges_push_back(const Halfedge& h, const Halfedge& g)*

appends a copy of *h* and a copy of *g* to *hds* and makes them opposite to each other. Returns a handle of the copy of *h*.

Halfedge_handle *hds.edges_push_back(const Halfedge& h)*

appends a copy of *h* and a copy of *h*→*opposite()* to *hds* and makes them opposite to each other. Returns a handle of the copy of *h*.
Precondition: h→*opposite()* denotes a halfedge.

Face_handle *hds.faces_push_back(const Face& f)*

appends a copy of *f* to *hds*. Returns a handle of the new face.

Removal

Erasing single elements is optional and indicated with the type tag *Supports_removal*. The *pop_back* and the *clear* member functions are mandatory. If vertices or faces are not supported for a HalfedgeDS< Traits,Items,Alloc> the *pop_back* and the *clear* member functions must be provided as null operations.

void *hds.vertices_pop_front()* removes the first vertex if vertices are supported and *Supports_removal* ≡ *CGAL::Tag_true*.

void *hds.vertices_pop_back()* removes the last vertex.

void *hds.vertices_erase(Vertex_handle v)* removes the vertex *v* if vertices are supported and *Supports_removal* ≡ *CGAL::Tag_true*.

void *hds.vertices_erase(Vertex_handle first, Vertex_handle last)*

removes the range of vertices [*first*,*last*) if vertices are supported and *Supports_removal* ≡ *CGAL::Tag_true*.

void *hds.edges_pop_front()* removes the first two halfedges if *Supports_removal* ≡ *CGAL::Tag_true*.

void *hds.edges_pop_back()* removes the last two halfedges.

void *hds.edges_erase(Halfedge_handle h)* removes the pair of halfedges *h* and *h*→*opposite()* if *Supports_removal* ≡ *CGAL::Tag_true*.

<code>void</code>	<code>hds.edges_erase(Halfedge_handle first, Halfedge_handle last)</code>	removes the range of edges $[first, last)$ if <i>Supports_removal</i> \equiv <i>CGAL::Tag_true</i> .
<code>void</code>	<code>hds.faces_pop_front()</code>	removes the first face if faces are supported and <i>Supports_removal</i> \equiv <i>CGAL::Tag_true</i> .
<code>void</code>	<code>hds.faces_pop_back()</code>	removes the last face.
<code>void</code>	<code>hds.faces_erase(Face_handle f)</code>	removes the face <i>f</i> if faces are supported and <i>Supports_removal</i> \equiv <i>CGAL::Tag_true</i> .
<code>void</code>	<code>hds.faces_erase(Face_handle first, Face_handle last)</code>	removes the range of faces $[first, last)$ if faces are supported and <i>Supports_removal</i> \equiv <i>CGAL::Tag_true</i> .
<code>void</code>	<code>hds.vertices_clear()</code>	removes all vertices.
<code>void</code>	<code>hds.edges_clear()</code>	removes all halfedges.
<code>void</code>	<code>hds.faces_clear()</code>	removes all faces.
<code>void</code>	<code>hds.clear()</code>	removes all elements.

— advanced —

Operations with Border Halfedges

The following notion of *border halfedges* is particular useful where the halfedge data structure is used to model surfaces with boundary, i.e., surfaces with missing faces or open regions. Halfedges incident to an open region are called *border halfedges*. A halfedge is a *border edge* if the halfedge itself or its opposite halfedge is a border halfedge. The only requirement to work with border halfedges is that the *Halfedge* class provides a member function *is_border()* returning a *bool*. Usually, the halfedge data structure supports faces and the value of the default constructor of the face handle will indicate a border halfedge, but this may not be the only possibility. The *is_border()* predicate divides the edges into two classes, the border edges and the non-border edges. The following normalization reorganizes the sequential storage of the edges such that the non-border edges precede the border edges, and that for each border edge the latter of the two halfedges is a border halfedge (the first one might be a border halfedge too). The normalization stores the number of border halfedges, as well as the halfedge iterator where the border edges start at, within the halfedge data structure. These values will be invalid after further halfedge insertions or removals and changes in the border status of a halfedge. There is no automatic update required.

<code>void</code>	<code>hds.normalize_border()</code>	sorts halfedges such that the non-border edges precede the border edges. For each border edge that is incident to a face, the halfedge iterator will reference the halfedge incident to the face right before the halfedge incident to the open region.
-------------------	-------------------------------------	---

Size *hds.size_of_border_halfedges() const*

number of border halfedges. An edge with no incident face counts as two border halfedges.

Precondition: *normalize_border()* has been called and no halfedge insertion or removal and no change in border status of the halfedges have occurred since then.

Size *hds.size_of_border_edges() const*

number of border edges. If *size_of_border_edges()* is equal to *size_of_border_halfedges()* all border edges are incident to a face on one side and to an open region on the other side.

Precondition: *normalize_border()* has been called and no halfedge insertion or removal and no change in border status of the halfedges have occurred since then.

Halfedge_iterator *hds.border_halfedges_begin()*

halfedge iterator starting with the border edges. The range [*halfedges_begin()*, *border_halfedges_begin()*) denotes all non-border edges. The range [*border_halfedges_begin()*, *halfedges_end()*) denotes all border edges.

Precondition: *normalize_border()* has been called and no halfedge insertion or removal and no change in border status of the halfedges have occurred since then.

Implementation

Classes parameterized with a halfedge data structure, such as *CGAL::Polyhedron_3*, need to declare a class template as one of its template parameters for the *HalfedgeDS<Traits,Items,Alloc>*. For compilers not supporting this (i.e. the flag *CGAL_CFG_NO_TMPL_IN_TMPL_PARAM* is set), the following workaround is required,

which defines a `HalfedgeDS<Traits,Items,Alloc>` as a normal class that contains a member class template named `HDS`, which is the actual halfedge data structure as defined here. The following program fragment illustrates this workaround:

```
#ifndef CGAL_CFG_NO_TMPL_IN_TMPL_PARAM
    template <class Traits, class Items, class Alloc>
    class HalfedgeDS {
    public:
        typedef HalfedgeDS<Traits,Items,Alloc> Self;
        HalfedgeDS_vector(); // constructors
#else
    struct HalfedgeDS {
    template <class Traits, class Items, class Alloc>
    class HDS {
    public:
        typedef HDS<Traits,Items,Alloc> Self;
        HDS(); // constructors
#endif
        // ... further member functions. Self denotes the HalfedgeDS.
    };
#ifdef CGAL_CFG_NO_TMPL_IN_TMPL_PARAM
    };
#endif
```

HalfedgeDSHalfedge

Definition

The concept `HalfedgeDSHalfedge` defines the requirements for the local *Halfedge* type in the *HalfedgeDS* concept. It is also required in the *Halfedge_wrapper*<*Refs*,*Traits*> member class template of an items class, see the *HalfedgeDSItems* concept.

A halfedge is an oriented edge between two vertices. It is always paired with a halfedge pointing in the opposite direction. The *opposite()* member function returns this halfedge of opposite orientation. The *next()* member function points to the successor halfedge along the face – or if the halfedge is a border halfedge – along the open region. A halfedge optionally stores a reference to the previous halfedge along the face, a reference to an incident vertex, and a reference to an incident face. Type tags indicate whether the related member functions are supported. Figure 26.3 depicts the relationship between a halfedge and its incident halfedges, vertices, and faces.

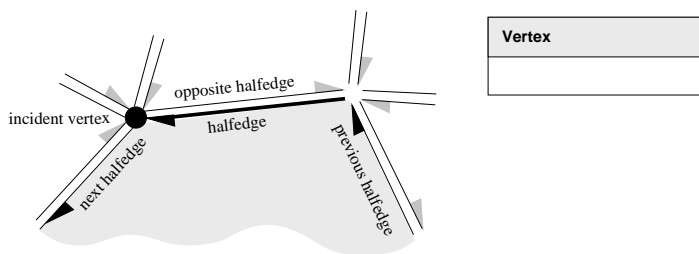

Figure 26.3: The three classes *Vertex*, *Halfedge*, and *Face* of the halfedge data structure. Member functions with shaded background are mandatory. The others are optionally supported.

For the protection of the integrity of the data structure classes such as *CGAL::Polyhedron_3* are allowed to redefine the modifying member functions to be private. In order to make them accessible for the halfedge data structure they must be derived from a base class *Base* where the modifying member functions are still public. Even more protection is provided for the *set_opposite()* member function. The base class *Base_base* provides access to it. (The protection could be bypassed also by an user, but not by accident.)

Types

<i>HalfedgeDSHalfedge:: HalfedgeDS</i>	instantiated <i>HalfedgeDS</i> (\equiv <i>Refs</i>).
<i>HalfedgeDSHalfedge:: Base</i>	base class that allows modifications.
<i>HalfedgeDSHalfedge:: Base_base</i>	base class to access <i>set_opposite()</i> .
<i>HalfedgeDSHalfedge:: Vertex</i>	model of <i>HalfedgeDSVertex</i> .
<i>HalfedgeDSHalfedge:: Face</i>	model of <i>HalfedgeDSFace</i> .
<i>HalfedgeDSHalfedge:: Vertex_handle</i>	handle to vertex.
<i>HalfedgeDSHalfedge:: Halfedge_handle</i>	handle to halfedge.
<i>HalfedgeDSHalfedge:: Face_handle</i>	handle to face.
<i>HalfedgeDSHalfedge:: Vertex_const_handle</i>	
<i>HalfedgeDSHalfedge:: Halfedge_const_handle</i>	
<i>HalfedgeDSHalfedge:: Face_const_handle</i>	
<i>HalfedgeDSHalfedge:: Supports_halfedge_prev</i>	<i>CGAL::Tag_true</i> or <i>CGAL::Tag_false</i> .

<i>HalfedgeDSHalfedge:: Supports_halfedge_vertex</i>	~
<i>HalfedgeDSHalfedge:: Supports_halfedge_face</i>	~

Creation

<i>HalfedgeDSHalfedge h;</i>	default constructor.
------------------------------	----------------------

Operations

<i>Halfedge_handle</i>	<i>h.opposite()</i>	
<i>Halfedge_const_handle</i>	<i>h.opposite() const</i>	the opposite halfedge.
<i>void</i>	<i>h.set_opposite(Halfedge_handle h)</i>	sets opposite halfedge to <i>h</i> .

<i>Halfedge_handle</i>	<i>h.next()</i>	
<i>Halfedge_const_handle</i>	<i>h.next() const</i>	the next halfedge around the face.
<i>void</i>	<i>h.set_next(Halfedge_handle h)</i>	sets next halfedge to <i>h</i> .

<i>bool</i>	<i>h.is_border() const</i>	is true if <i>h</i> is a border halfedge.
-------------	----------------------------	---

Operations available if *Supports_halfedge_prev* \equiv *CGAL::Tag_true*

<i>Halfedge_handle</i>	<i>h.prev()</i>	
<i>Halfedge_const_handle</i>	<i>h.prev() const</i>	the previous halfedge around the face.
<i>void</i>	<i>h.set_prev(Halfedge_handle h)</i>	sets prev halfedge to <i>h</i> .

Operations available if *Supports_halfedge_vertex* \equiv *CGAL::Tag_true*

<i>Vertex_handle</i>	<i>h.vertex()</i>	
<i>Vertex_const_handle</i>	<i>h.vertex() const</i>	the incident vertex of <i>h</i> .
<i>void</i>	<i>h.set_vertex(Vertex_handle v)</i>	sets incident vertex to <i>v</i> .

Operations available if *Supports_halfedge_face* \equiv *CGAL::Tag_true*

<i>Face_handle</i>	<i>h.face()</i>	
<i>Face_const_handle</i>	<i>h.face() const</i>	the incident face of <i>h</i> . If <i>h</i> is a border halfedge the result is default construction of the handle.
<i>void</i>	<i>h.set_face(Face_handle f)</i>	sets incident face to <i>f</i> .

HalfedgeDSItems

Definition

The concept `HalfedgeDSItems` wraps the three item types – vertex, halfedge, and face – for a halfedge data structure. A `HalfedgeDSItems` contains three member class templates named `Vertex_wrapper`, `Halfedge_wrapper`, and `Face_wrapper`, each with two template parameters, `Refs` and `Traits`. `Refs` requires an instantiated halfedge data structure `HalfedgeDS` as argument, `Traits` is a geometric traits class supplied by the class that uses the halfedge data structure as internal representation. `Traits` is not used by the halfedge data structure itself. These three member class templates provide a local type named `Vertex`, `Halfedge`, and `Face` respectively. The requirements on these types are described on page 1823, page 1819, and page 1817 respectively.

Types

<code>HalfedgeDSItems::Vertex_wrapper<Refs,Traits>::Vertex</code>	model of <code>HalfedgeDSVertex</code> .
<code>HalfedgeDSItems::Halfedge_wrapper<Refs,Traits>::Halfedge</code>	model of <code>HalfedgeDSHalfedge</code> .
<code>HalfedgeDSItems::Face_wrapper<Refs,Traits>::Face</code>	model of <code>HalfedgeDSFace</code> .

Has Models

<code>CGAL::HalfedgeDS_min_items</code>	page 1847
<code>CGAL::HalfedgeDS_items_2</code>	page 1841
<code>CGAL::Polyhedron_items_3</code>	page 1786

Example

The following example shows the canonical implementation of the `CGAL::HalfedgeDS_min_items` class. It uses the base classes for the item types that are provided in the library.

```
struct HalfedgeDS_min_items {
    template < class Refs, class Traits>
    struct Vertex_wrapper {
        typedef CGAL::HalfedgeDS_vertex_min_base< Refs>    Vertex;
    };
    template < class Refs, class Traits>
    struct Halfedge_wrapper {
        typedef CGAL::HalfedgeDS_halfedge_min_base< Refs> Halfedge;
    };
};
```

```
};  
template < class Refs, class Traits>  
struct Face_wrapper {  
    typedef CGAL::HalfedgeDS_face_min_base< Refs>    Face;  
};  
};
```

See page [1841](#) for an example implementation of the *CGAL::HalfedgeDS_items_2* class.

HalfedgeDSVertex

Definition

The concept `HalfedgeDSVertex` defines the requirements for the local `Vertex` type in the `HalfedgeDS` concept. It is also required in the `Vertex_wrapper<Refs,Traits>` member class template of an items class, see the `HalfedgeDSItems` concept.

A vertex optionally stores a reference to an incident halfedge that points to the vertex. A type tag indicates whether the related member functions are supported. Figure 26.3 depicts the relationship between a halfedge and its incident halfedges, vertices, and faces.

For the protection of the integrity of the data structure classes such as *CGAL::Polyhedron_3* are allowed to redefine the modifying member functions to be private. In order to make them accessible for the halfedge data structure they must be derived from a base class *Base* where the modifying member functions are still public. (The protection could be bypassed by an user, but not by accident.)

Types

<i>HalfedgeDSVertex:: HalfedgeDS</i>	instantiated <i>HalfedgeDS</i> (\equiv <i>Refs</i>).
<i>HalfedgeDSVertex:: Base</i>	base class that allows modifications.
<i>HalfedgeDSVertex:: Halfedge</i>	model of <i>HalfedgeDSHalfedge</i> .
<i>HalfedgeDSVertex:: Face</i>	model of <i>HalfedgeDSFace</i> .
<i>HalfedgeDSVertex:: Vertex_handle</i>	handle to vertex.
<i>HalfedgeDSVertex:: Halfedge_handle</i>	handle to halfedge.
<i>HalfedgeDSVertex:: Face_handle</i>	handle to face.
<i>HalfedgeDSVertex:: Vertex_const_handle</i>	
<i>HalfedgeDSVertex:: Halfedge_const_handle</i>	
<i>HalfedgeDSVertex:: Face_const_handle</i>	
<i>HalfedgeDSVertex:: Supports_vertex_halfedge</i>	<i>CGAL::Tag_true</i> or <i>CGAL::Tag_false</i> .

Creation

<i>HalfedgeDSVertex</i> v;	default constructor.
----------------------------	----------------------

Operations available if *Supports_vertex_halfedge* \equiv *CGAL::Tag_true*

<i>Halfedge_handle</i>	<i>v.halfedge()</i>	
<i>Halfedge_const_handle</i>	<i>v.halfedge() const</i>	incident halfedge that points to <i>v</i> .
<i>void</i>	<i>v.set_halfedge(Halfedge_handle h)</i>	sets incident halfedge to <i>h</i> .

CGAL::HalfedgeDS_const_decorator<HDS>

Definition

The classes `CGAL::HalfedgeDS_items_decorator<HDS>`, `CGAL::HalfedgeDS_decorator<HDS>`, and `CGAL::HalfedgeDS_const_decorator<HDS>` provide additional functions to examine and to modify a halfedge data structure *HDS*. The class `CGAL::HalfedgeDS_items_decorator<HDS>` provides additional functions for vertices, halfedges, and faces of a halfedge data structure without knowing the containing halfedge data structure. The class `CGAL::HalfedgeDS_decorator<HDS>` stores a reference to the halfedge data structure and provides functions that modify the halfedge data structure, for example Euler-operators. The class `CGAL::HalfedgeDS_const_decorator<HDS>` stores a const reference to the halfedge data structure. It contains non-modifying functions, for example the test for validness of the data structure.

All these additional functions take care of the different capabilities a halfedge data structure may have or may not have. The functions evaluate the type tags of the halfedge data structure to decide on the actions. If a particular feature is not supported nothing is done. Note that for example the creation of new halfedges is mandatory for all halfedge data structures and will not appear here again.

```
#include <CGAL/HalfedgeDS_const_decorator.h>
```

Inherits From

`CGAL::HalfedgeDS_items_decorator<HDS>` page 1843

Creation

```
HalfedgeDS_const_decorator<HDS> D( const HDS& hds);
```

keeps internally a const reference to *hds*.

Validness Checks

A halfedge data structure has no definition of validness of its own, but a useful set of tests is defined with the following levels:

Level 0 The number of halfedges is even. All pointers except the vertex pointer and the face pointer for border halfedges are unequal to their respective default construction value. For all halfedges *h*: The opposite halfedge is different from *h* and the opposite of the opposite is equal to *h*. The next of the previous halfedge is equal to *h*. For all vertices *v*: the incident vertex of the incident halfedge of *v* is equal to *v*. The halfedges around *v* starting with the incident halfedge of *v* form a cycle. For all faces *f*: the incident face of the incident halfedge of *f* is equal to *f*. The halfedges around *f* starting with the incident halfedge of *f* form a cycle. Redundancies among internal variables are tested, e.g., that iterators enumerate as many items as the related size value indicates.

Level 1 All tests of level 0. For all halfedges *h*: The incident vertex of *h* exists and is equal to the incident vertex of the opposite of the next halfedge. The incident face (or hole) of *h* is equal to the incident face (or hole) of the next halfedge.

Level 2 All tests of level 1. The sum of all halfedges that can be reached through the vertices must be equal to the number of all halfedges, i.e., all halfedges incident to a vertex must form a single cycle.

Level 3 All tests of level 2. The sum of all halfedges that can be reached through the faces must be equal to the number of all halfedges, i.e., all halfedges surrounding a face must form a single cycle (no holes in faces).

Level 4 All tests of level 3 and *normalized_border_is_valid*.

bool

D.is_valid(bool verbose = false, int level = 0)

returns *true* if the halfedge data structure *hds* is valid with respect to the *level* value as defined above. If *verbose* is *true*, statistics are written to *cerr*.

bool

D.normalized_border_is_valid(bool verbose = false)

returns *true* if the border halfedges are in normalized representation, which is when enumerating all halfedges with the halfedge iterator the following holds: The non-border edges precede the border edges. For border edges, the second halfedge is a border halfedge. (The first halfedge may or may not be a border halfedge.) The halfedge iterator *border_halfedges_begin()* denotes the first border edge. If *verbose* is *true*, statistics are written to *cerr*.

CGAL::HalfedgeDS_decorator<HDS> [page 1827](#)

Example

The following program fragment illustrates the implementation of a *is_valid()* member function for a simplified polyhedron class. We assume here that the level three check is the appropriate default for polyhedral surfaces.

```
namespace CGAL {
    template <class Traits>
    class Polyhedron {
        typedef HalfedgeDS_default<Traits> HDS;
        HDS hds;
    public:
        // ...
        bool is_valid( bool verb = false, int level = 0) const {
            Verbose_ostream verr(verb);
            verr << "begin Polyhedron::is_valid( verb=true, level = " <<
level
                << "):" << std::endl;
            HalfedgeDS_const_decorator<HDS> decorator(hds);
            bool valid = decorator.is_valid( verb, level + 3);
            // further checks ...
        }
    };
}
```

CGAL::HalfedgeDS_decorator<HDS>

Definition

The classes *CGAL::HalfedgeDS_items_decorator<HDS>*, *CGAL::HalfedgeDS_decorator<HDS>*, and *CGAL::HalfedgeDS_const_decorator<HDS>* provide additional functions to examine and to modify a halfedge data structure *HDS*. The class *CGAL::HalfedgeDS_items_decorator<HDS>* provides additional functions for vertices, halfedges, and faces of a halfedge data structure without knowing the containing halfedge data structure. The class *CGAL::HalfedgeDS_decorator<HDS>* stores a reference to the halfedge data structure and provides functions that modify the halfedge data structure, for example Euler-operators. The class *CGAL::HalfedgeDS_const_decorator<HDS>* stores a const reference to the halfedge data structure. It contains non-modifying functions, for example the test for validness of the data structure.

All these additional functions take care of the different capabilities a halfedge data structure may have or may not have. The functions evaluate the type tags of the halfedge data structure to decide on the actions. If a particular feature is not supported nothing is done. Note that for example the creation of new halfedges is mandatory for all halfedge data structures and will not appear here again.

```
#include <CGAL/HalfedgeDS_decorator.h>
```

Inherits From

CGAL::HalfedgeDS_items_decorator<HDS> page [1843](#)

Creation

HalfedgeDS_decorator<HDS> *D*(*HDS& hds*); keeps internally a reference to *hds*.

Creation of New Items

Vertex_handle *D.vertices_push_back*(*Vertex v*) appends a copy of *v* to *hds* if vertices are supported. Returns a handle of the new vertex, or *Vertex_handle()* otherwise.

Face_handle *D.faces_push_back*(*Face f*) appends a copy of *f* to *hds* if faces are supported. Returns a handle of the new face, or *Face_handle()* otherwise.

Creation of New Composed Items

Halfedge_handle *D.create_loop*() returns handle of a halfedge from a newly created loop in *hds* consisting of a single closed edge, one vertex and two faces (if supported respectively).

Halfedge_handle *D.create_segment*() returns a halfedge from a newly created segment in *hds* consisting of a single open edge, two vertices and one face (if supported respectively).

Removal of Elements

The following member functions do *not* update affected incidence relations except if mentioned otherwise.

<i>void</i>	<i>D.vertices_pop_front()</i>	removes the first vertex if vertices are supported. <i>Requirement:</i> <i>Supports_removal</i> \equiv <i>CGAL::Tag_true</i> .
<i>void</i>	<i>D.vertices_pop_back()</i>	removes the last vertex if vertices are supported.
<i>void</i>	<i>D.vertices_erase(Vertex_handle v)</i>	removes the vertex <i>v</i> if vertices are supported. <i>Requirement:</i> <i>Supports_removal</i> \equiv <i>CGAL::Tag_true</i> .
<i>void</i>	<i>D.vertices_erase(Vertex_handle first, Vertex_handle last)</i>	removes the range $[first, last)$ if vertices are supported. <i>Requirement:</i> <i>Supports_removal</i> \equiv <i>CGAL::Tag_true</i> .
<i>void</i>	<i>D.faces_pop_front()</i>	removes the first face if faces are supported. <i>Requirement:</i> <i>Supports_removal</i> \equiv <i>CGAL::Tag_true</i> .
<i>void</i>	<i>D.faces_pop_back()</i>	removes the last face if faces are supported.
<i>void</i>	<i>D.faces_erase(Face_handle f)</i>	removes the face <i>f</i> if faces are supported. <i>Requirement:</i> <i>Supports_removal</i> \equiv <i>CGAL::Tag_true</i> .
<i>void</i>	<i>D.faces_erase(Face_handle first, Face_handle last)</i>	removes the range $[first, last)$ if faces are supported. <i>Requirement:</i> <i>Supports_removal</i> \equiv <i>CGAL::Tag_true</i> .
<i>void</i>	<i>D.erase_face(Halfedge_handle h)</i>	removes the face incident to <i>h</i> from <i>hds</i> and changes all halfedges incident to the face into border edges or removes them from the halfedge data structure if they were already border edges. If this creates isolated vertices they get removed as well. See <i>make_hole(h)</i> for a more specialized variant. <i>Precondition:</i> <i>h->is_border()</i> \equiv <i>false</i> . <i>Requirement:</i> If faces are supported, <i>Supports_removal</i> \equiv <i>CGAL::Tag_true</i> .
<i>void</i>	<i>D.erase_connected_component(Halfedge_handle h)</i>	removes the vertices, halfedges, and faces that belong to the connected component of <i>h</i> . <i>Precondition:</i> For all halfedges <i>g</i> in the connected component <i>g.next()</i> \neq <i>Halfedge_handle()</i> . <i>Requirement:</i> <i>Supports_removal</i> \equiv <i>CGAL::Tag_true</i> .
<i>unsigned int</i>	<i>D.keep_largest_connected_components(unsigned int nb_components_to_keep)</i>	Erases the small connected components and the isolated vertices. Keep <i>nb_components_to_keep</i> largest connected components. Returns the number of connected components erased (ignoring isolated vertices). <i>Requirement:</i> supports vertices, halfedges, and removal operation.

Modifying Functions (For Border Halfedges)

Halfedge_handle *D.make_hole(Halfedge_handle h)*

removes the face incident to *h* from *hds* and creates a hole.

Precondition: *h* != *Halfedge_handle()* and *!(h->is_border())*.

Requirement: If faces are supported, *Supports_removal* \equiv *CGAL::Tag_true*.

Halfedge_handle *D.fill_hole(Halfedge_handle h)*

fills the hole incident to *h* with a new face from *hds*. Returns *h*.

Precondition: *h* != *Halfedge_handle()* and *h->is_border()*.

Halfedge_handle *D.fill_hole(Halfedge_handle h, Face f)*

fills the hole incident to *h* with a copy of face *f*. Returns *h*.

Precondition: *h* != *Halfedge_handle()* and *h->is_border()*.

Halfedge_handle *D.add_face_to_border(Halfedge_handle h, Halfedge_handle g)*

extends the surface with a new face from *hds* into the hole incident to *h* and *g*. It creates a new edge connecting the vertex denoted by *g* with the vertex denoted by *h* and fills this separated part of the hole with a new face, such that the new face is incident to *g*. Returns the new halfedge that is incident to the new face.

Precondition: *h* != *Halfedge_handle()*, *g* != *Halfedge_handle()*, *h->is_border()*, *g->is_border()* and *g* can be reached along the hole starting with *h*.

Halfedge_handle *D.add_face_to_border(Halfedge_handle h, Halfedge_handle g, Face f)*

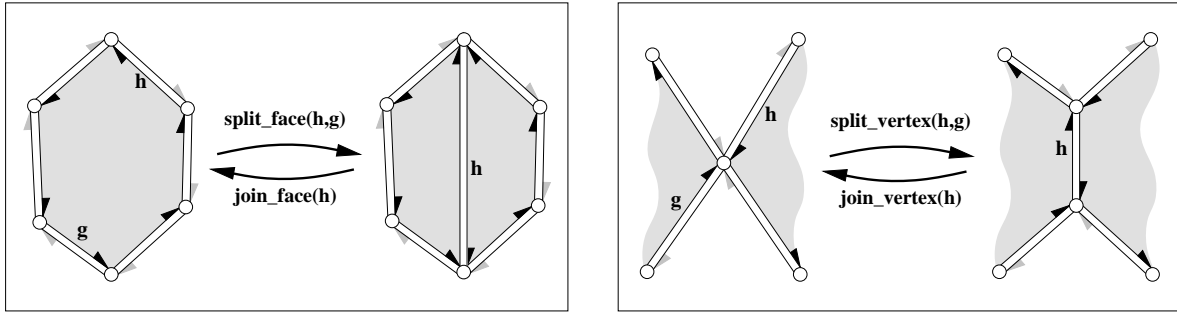

extends the surface with a copy of face *f* into the hole incident to *h* and *g*. It creates a new edge connecting the tip of *g* with the tip of *h* and fills this separated part of the hole with a copy of face *f*, such that the new face is incident to *g*. Returns the new halfedge that is incident to the new face.

Precondition: *h* != *Halfedge_handle()*, *g* != *Halfedge_handle()*, *h->is_border()*, *g->is_border()* and *g* can be reached along the hole starting with *h*.

Modifying Functions (Euler Operators)

The following Euler operations modify consistently the combinatorial structure of the halfedge data structure. The geometry remains unchanged. Note that well known graph operations are also captured with these Euler operators, for example an edge contraction is equal to a *join_vertex()* operation, or an edge removal to *join_face()*.

Given a halfedge data structure *hds* and a halfedge handle *h* four special applications of the Euler operators are worth mentioning: *split_vertex(h,h)* results in an antenna emanating from the tip of *h*; *split_vertex(h,h->next()->opposite())* results in an edge split of the halfedge *h->next* with a new vertex in-between; *split_face(h,h)* results in a loop directly following *h*; and *split_face(h,h->next())* results in a bridge parallel to the halfedge *h->next* with a new face in-between.

Halfedge_handle *D.split_face(Halfedge_handle h, Halfedge_handle g)*

splits the face incident to *h* and *g* into two faces with a new diagonal between the two vertices denoted by *h* and *g* respectively. The second (new) face obtained from *hds* is a copy of the first face. Returns *h->next()* after the operation, i.e., the new diagonal. The new face is to the right of the new diagonal, the old face is to the left. The time is proportional to the distance from *h* to *g* around the face.

Halfedge_handle *D.join_face(Halfedge_handle h)*

joins the two faces incident to *h*. The face incident to *h->opposite()* gets removed from *hds*. Both faces might be holes. Returns the predecessor of *h* around the face. The invariant *join_face(split_face(h, g))* returns *h* and keeps the data structure unchanged. The time is proportional to the size of the face removed and the time to compute *h->prev()*.

Requirement: Supports_removal \equiv *CGAL::Tag_true*.

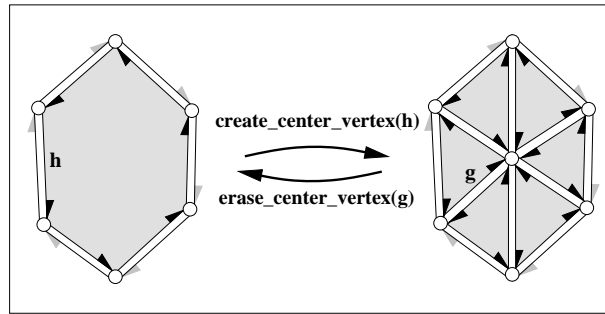

Halfedge_handle *D.split_vertex(Halfedge_handle h, Halfedge_handle g)*

splits the vertex incident to *h* and *g* into two vertices and connects them with a new edge. The second (new) vertex obtained from *hds* is a copy of the first vertex. Returns *h->next()->opposite()* after the operation, i.e., the new edge in the orientation towards the new vertex. The time is proportional to the distance from *h* to *g* around the vertex.

Halfedge_handle *D.join_vertex(Halfedge_handle h)*

joins the two vertices incident to *h*. The vertex denoted by *h->opposite()* gets removed by *hds*. Returns the predecessor of *h* around the vertex, i.e., *h->opposite()->prev()*. The invariant *join_vertex(split_vertex(h, g))* returns *h* and keeps the polyhedron unchanged. The time is proportional to the degree of the vertex removed and the time to compute *h->prev()* and *h->opposite()->prev()*.

Requirement: Supports_removal \equiv *CGAL::Tag_true*.

Halfedge_handle *D.create_center_vertex(Halfedge_handle h)*

barycentric triangulation of $h \rightarrow \text{face}()$. Creates a new vertex, a copy of $h \rightarrow \text{vertex}()$, and connects it to each vertex incident to $h \rightarrow \text{face}()$ splitting $h \rightarrow \text{face}()$ into triangles. h remains incident to the original face, all other triangles are copies of this face. Returns the halfedge $h \rightarrow \text{next}()$ after the operation, i.e., a halfedge pointing to the new vertex. The time is proportional to the size of the face.

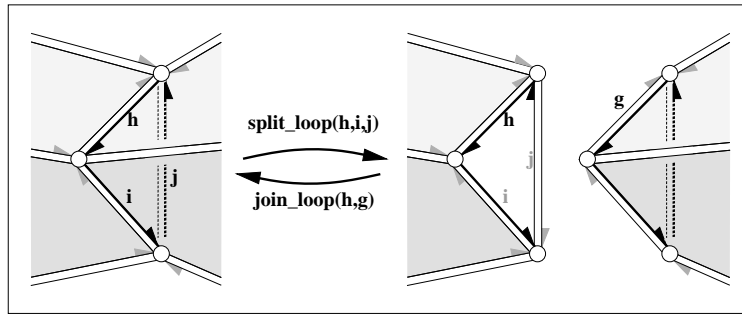

Precondition: h is not a border halfedge.

Halfedge_handle *D.erase_center_vertex(Halfedge_handle g)*

reverses *create_center_vertex*. Erases the vertex pointed to by g and all incident halfedges thereby merging all incident faces. Only $g \rightarrow \text{face}()$ remains. The neighborhood of $g \rightarrow \text{vertex}()$ may not be triangulated, it can have larger faces. Returns the halfedge $g \rightarrow \text{prev}()$. Thus, the invariant $h == \text{erase_center_vertex}(\text{create_center_vertex}(h))$ holds if h is not a border halfedge. The time is proportional to the sum of the size of all incident faces.

Precondition: None of the incident faces of $g \rightarrow \text{vertex}()$ is a hole. There are at least two distinct faces incident to the faces that are incident to $g \rightarrow \text{vertex}()$. (This prevents the operation from collapsing a volume into two faces glued together with opposite orientations, such as would happen with any vertex of a tetrahedron.)

Requirement: *Supports_removal* \equiv *CGAL::Tag_true*.

Halfedge_handle *D.split_loop(Halfedge_handle h, Halfedge_handle i, Halfedge_handle j)*

cuts the halfedge data structure into two parts along the cycle (h, i, j) . Three new vertices (one copy for each vertex in the cycle) and three new halfedges (one copy for each halfedge in the cycle), and two new triangles are created. h, i, j will be incident to the first new triangle. The return value will be the halfedge incident to the second new triangle which is the copy of h -*opposite()*.

Precondition: h, i, j denote distinct, consecutive vertices of the halfedge data structure and form a cycle: i.e., $h \rightarrow \text{vertex}() == i \rightarrow \text{opposite}() \rightarrow \text{vertex}(), \dots, j \rightarrow \text{vertex}() == h \rightarrow \text{opposite}() \rightarrow \text{vertex}()$.

Halfedge_handle *D.join_loop(Halfedge_handle h, Halfedge_handle g)*

glues the boundary of the two faces denoted by h and g together and returns h . Both faces and the vertices along the face denoted by g gets removed. Both faces may be holes. The invariant $\text{join_loop}(h, \text{split_loop}(h, i, j))$ returns h and keeps the data structure unchanged.

Precondition: The faces denoted by h and g are different and have equal degree (i.e., number of edges).

Requirement: *Supports_removal* \equiv *CGAL::Tag_true*.

Validness Checks

These operations are the same as for *CGAL::HalfedgeDS_const_decorator<HDS>*. See their documentation on page 1825.

bool *D.is_valid(bool verbose = false, int level = 0)*

bool *D.normalized_border_is_valid(bool verbose = false)*

Miscellaneous

void *D.inside_out()* reverses face orientations.
Precondition: *is_valid()* of level three.

Example

The following program fragment illustrates the implementation of the Euler operator *split_vertex()* for a simplified polyhedron class.

```
template <class Traits>
namespace CGAL {
    class Polyhedron {
        typedef HalfedgeDS_default<Traits> HDS;
        HDS hds;
    public:
        // ...
        Halfedge_handle split_vertex( Halfedge_handle h, Halfedge_handle
g) {
            HalfedgeDS_decorator<HDS> D(hds);
            // Stricter preconditions than for HalfedgeDS only.
            CGAL_precondition( D.get_vertex(h) == D.get_vertex(g));
            CGAL_precondition( h != g);
            return D.split_vertex( h, g);
        }
    };
}
```

CGAL::HalfedgeDS_default<Traits,HalfedgeDSItems,Alloc>

Definition

```
template < class Traits,
           class HalfedgeDSItems = CGAL::HalfedgeDS_items_2,
           class Alloc = CGAL_ALLOCATOR(int)>
class HalfedgeDS_default;
```

The class *HalfedgeDS_default*<Traits,HalfedgeDSItems,Alloc> is a model for the *HalfedgeDS* concept. The second template parameter *HalfedgeDSItems* has a default argument *CGAL::HalfedgeDS_items_2*. The third template parameter *Alloc* uses the CGAL default allocator as default setting. *HalfedgeDS_default*<Traits,HalfedgeDSItems,Alloc> is a list-based representation with bidirectional iterators that supports removal.

```
#include <CGAL/HalfedgeDS_default.h>
```

Is Model for the Concepts

HalfedgeDS<Traits,Items,Alloc> page [1809](#)

Types

```
typedef bidirectional_iterator_tag    iterator_category;
typedef CGAL::Tag_true                Supports_removal;
```

CGAL::HalfedgeDS_decorator<HDS> page [1827](#)
CGAL::HalfedgeDS_const_decorator<HDS> page [1825](#)

Implementation

Currently, *HalfedgeDS_default*<Traits,HalfedgeDSItems,Alloc> is derived from *CGAL::HalfedgeDS_list*<Traits>. The copy constructor and the assignment operator need $O(n)$ time with n the total number of vertices, halfedges, and faces. The former suboptimal implementation with an $O(n \log n)$ runtime has been replaced with a faster implementation based on hashing for the pointer lookup.

Due to a workaround for the flag *CGAL_CFG_NO_TMPL_IN_TMPL_PARAM*, a halfedge data structure cannot be instantiated directly. For the *HalfedgeDS_default*<Traits,HalfedgeDSItems,Alloc> a macro simplifies its direct use. However, when using a halfedge data structure as an argument for another class template, the class template name *HalfedgeDS_default* must be used, not the macro.

```
// The macro definition.
#ifndef CGAL_CFG_NO_TMPL_IN_TMPL_PARAM
    #define CGAL_HALFEDGEDS_DEFAULT  ::CGAL::HalfedgeDS_default
#else
    #define CGAL_HALFEDGEDS_DEFAULT  ::CGAL::HalfedgeDS_default::HDS
#endif

// The direct instantiation of the default HalfedgeDS given a Traits
class.
typedef CGAL_HALFEDGEDS_DEFAULT<Traits> HDS;
```

CGAL::HalfedgeDS_face_base<Refs>

Definition

The class *HalfedgeDS_face_base<Refs>* is a model of the *HalfedgeDSFace* concept. *Refs* is an instantiation of a *HalfedgeDS*. The template declaration of *HalfedgeDS_face_base<Refs>* has three parameters with some defaults that allow to select various flavors of faces. The declaration is best explained with the two following declarations, essentially hiding an implementation dependent default setting:

```
template <class Refs, class T = CGAL::Tag_true>
class HalfedgeDS_face_base;
```

```
template <class Refs, class T, class Plane>
class HalfedgeDS_face_base;
```

HalfedgeDS_face_base<Refs> defines a face including a reference to an incident halfedge.

CGAL::HalfedgeDS_face_base<Refs,CGAL::Tag_false> is a face without a reference to an incident halfedge. It is empty besides the required type definitions. It can be used for deriving own faces. See also *CGAL::HalfedgeDS_face_min_base<Refs>*.

CGAL::HalfedgeDS_face_base<Refs,CGAL::Tag_true,Plane> is a face with a reference to an incident halfedge and it stores a plane equation of type *Plane*. It can be used as a face for a model of the *PolyhedronItems_3* concept.

CGAL::HalfedgeDS_face_base<Refs,CGAL::Tag_false,Plane> is a face without a reference to an incident halfedge and it stores a plane equation of type *Plane*. It can be used as a face for a model of the *PolyhedronItems_3* concept.

```
#include <CGAL/HalfedgeDS_face_base.h>
```

Is Model for the Concepts

HalfedgeDSFace page [1817](#)

Types

HalfedgeDS_face_base<Refs>::Plane plane type for three argument version.

Creation

HalfedgeDS_face_base<Refs> f; default constructor.
HalfedgeDS_face_base<Refs> f(Plane pln); initialized with plane *pln*.

Operations

Plane& *f.plane()*
const Plane& *f.plane() const*

CGAL::HalfedgeDS_halfedge_base<Refs>

Definition

The class *HalfedgeDS_halfedge_base*<Refs> is a model of the *HalfedgeDSHalfedge* concept. *Refs* is an instantiation of a *HalfedgeDS*. The full declaration states four template parameters:

```
template < class Refs,
           class Tag_prev = CGAL::Tag_true,
           class Tag_vertex = CGAL::Tag_true,
           class Tag_face = CGAL::Tag_true>
class HalfedgeDS_halfedge_base;
```

If *Tag_prev* \equiv *CGAL::Tag_true* a reference to the previous halfedge is supported.

If *Tag_vertex* \equiv *CGAL::Tag_true* an incident vertex is supported.

If *Tag_face* \equiv *CGAL::Tag_true* an incident face is supported.

In all cases, a reference to the next halfedge and to the opposite halfedge is supported.

```
#include <CGAL/HalfedgeDS_halfedge_base.h>
```

Is Model for the Concepts

CGAL::HalfedgeDS_items_2

Definition

The class *HalfedgeDS_items_2* is a model of the *HalfedgeDSItems* concept. It uses the default types for vertices, halfedges, and faces that declare all incidences supported by a *HalfedgeDS*. The vertex also contains a point of type *Traits::Point_2*, where *Traits* is the template argument of the corresponding *HalfedgeDS*.

```
#include <CGAL/HalfedgeDS_items_2.h>
```

Is Model for the Concepts

HalfedgeDSItems page [1821](#)

See Also

CGAL::HalfedgeDS_min_items page [1847](#)
CGAL::Polyhedron_items_3 page [1786](#)
HalfedgeDS<Traits,Items,Alloc> page [1809](#)
PolyhedronItems_3 page [1784](#)
CGAL::HalfedgeDS_vertex_base<Refs> page [1851](#)
CGAL::HalfedgeDS_halfedge_base<Refs> page [1839](#)
CGAL::HalfedgeDS_face_base<Refs> page [1836](#)

Example

The following example shows the canonical implementation of the *HalfedgeDS_items_2* class. It uses the base classes for the item types that are provided in the library.

```
struct HalfedgeDS_items_2 {
    template < class Refs, class Traits>
    struct Vertex_wrapper {
        typedef typename Traits::Point_2 Point;
        typedef CGAL::HalfedgeDS_vertex_base< Refs, Tag_true, Point>
Vertex;
    };
    template < class Refs, class Traits>
    struct Halfedge_wrapper {
        typedef CGAL::HalfedgeDS_halfedge_base< Refs> Halfedge;
    };
    template < class Refs, class Traits>
    struct Face_wrapper {
        typedef CGAL::HalfedgeDS_face_base< Refs> Face;
    };
};
```

The following example shows a class definition for a new items class derived from the *HalfedgeDS_items_2* class. It replaces the *Face_wrapper* with a new definition of a face that contains a member variable for color. The new face makes use of the face base class provided in the library.

```

// A face type with a color member variable.
template <class Refs>
struct My_face : public CGAL::HalfedgeDS_face_base<Refs> {
    CGAL::Color color;
    My_face() {}
    My_face( CGAL::Color c) : color(c) {}
};

// An items type using my face.
struct My_items : public CGAL::HalfedgeDS_items_2 {
    template <class Refs, class Traits>
    struct Face_wrapper {
        typedef My_face<Refs> Face;
    };
};

```

CGAL::HalfedgeDS_items_decorator<HDS>

Definition

The classes *CGAL::HalfedgeDS_items_decorator<HDS>*, *CGAL::HalfedgeDS_decorator<HDS>*, and *CGAL::HalfedgeDS_const_decorator<HDS>* provide additional functions to examine and to modify a halfedge data structure *HDS*. The class *CGAL::HalfedgeDS_items_decorator<HDS>* provides additional functions for vertices, halfedges, and faces of a halfedge data structure without knowing the containing halfedge data structure. The class *CGAL::HalfedgeDS_decorator<HDS>* stores a reference to the halfedge data structure and provides functions that modify the halfedge data structure, for example Euler-operators. The class *CGAL::HalfedgeDS_const_decorator<HDS>* stores a const reference to the halfedge data structure. It contains non-modifying functions, for example the test for validness of the data structure.

All these additional functions take care of the different capabilities a halfedge data structure may have or may not have. The functions evaluate the type tags of the halfedge data structure to decide on the actions. If a particular feature is not supported nothing is done. Note that for example the creation of new halfedges is mandatory for all halfedge data structures and will not appear here again.

```
#include <CGAL/HalfedgeDS_items_decorator.h>
```

Types

<i>HalfedgeDS_items_decorator<HDS>:: HalfedgeDS</i>	halfedge data structure.

```

default constructor.

Access Functions

<i>Halfedge_handle</i>	<i>D.get_vertex_halfedge(Vertex_handle v)</i>	returns the incident halfedge of <i>v</i> if supported, <i>Halfedge_handle()</i> otherwise.
------------------------	---	--

<i>Vertex_handle</i>	<i>D.get_vertex(Halfedge_handle h)</i>	returns the incident vertex of <i>h</i> if supported, <i>Vertex_handle()</i> otherwise.
----------------------	---	--

<i>Halfedge_handle</i>	<i>D.get_prev(Halfedge_handle h)</i>	returns the previous halfedge of <i>h</i> if supported, <i>Halfedge_handle()</i> otherwise.
------------------------	--	---

<i>Halfedge_handle</i> <i>D.find_prev(Halfedge_handle h)</i>	returns the previous halfedge of <i>h</i> . Uses the <i>prev()</i> method if supported or performs a search around the face using <i>next()</i> .
---	---

<i>Halfedge_handle</i>	<i>D.find_prev_around_vertex(Halfedge_handle h)</i>	returns the previous halfedge of <i>h</i> . Uses the <i>prev()</i> method if supported or performs a search around the vertex using <i>next()</i> .
------------------------	--	---

<i>Face_handle</i>	<i>D.get_face(Halfedge_handle h)</i>	returns the incident face of <i>h</i> if supported, <i>Face_handle()</i> otherwise.
--------------------	--	--

<i>Halfedge_handle</i>	<i>D.get_face_halfedge(Face_handle f)</i>	returns the incident halfedge of <i>f</i> if supported, <i>Halfedge_handle()</i> otherwise.
------------------------	--	---

Corresponding member functions for *const_handle*'s are provided as well.

Modifying Functions (Composed)

<i>void</i>	<i>D.close_tip(Halfedge_handle h)</i>	makes <i>h->opposite()</i> the successor of <i>h</i> .
-------------	--	---

void	<i>D.close_tip(Halfedge_handle h, Vertex_handle v)</i>
	makes <i>h->opposite()</i> the successor of <i>h</i> and sets the incident vertex of <i>h</i> to <i>v</i> .

<code>void</code>	<code>D.insert_tip(Halfedge_handle h, Halfedge_handle v)</code>
	<p>inserts the tip of the edge h into the halfedges around the vertex pointed to by v. Halfedge $h \rightarrow \text{opposite}()$ is the new successor of v and $h \rightarrow \text{next}()$ will be set to $v \rightarrow \text{next}()$. The vertex of h will be set to the vertex v refers to if vertices are supported.</p>

<i>void</i>	<i>D.remove_tip(Halfedge_handle h)</i>	removes the edge <i>h->next()->opposite()</i> from the halfedge circle around the vertex referred to by <i>h</i> . The new successor halfedge of <i>h</i> will be <i>h->next()->opposite()->next()</i> .
-------------	---	---

<i>void</i>	<i>D.insert_halfedge(Halfedge_handle h, Halfedge_handle f)</i>	inserts the halfedge <i>h</i> between <i>f</i> and <i>f->next()</i> . The face of <i>h</i> will be the one <i>f</i> refers to if faces are supported.
<i>void</i>	<i>D.remove_halfedge(Halfedge_handle h)</i>	removes edge <i>h->next()</i> from the halfedge circle around the face referred to by <i>h</i> . The new successor of <i>h</i> will be <i>h->next()->next()</i> .
<i>void</i>	<i>D.set_vertex_in_vertex_loop(Halfedge_handle h, Vertex_handle v)</i>	loops around the vertex incident to <i>h</i> and sets all vertex pointers to <i>v</i> . <i>Precondition: h != Halfedge_handle().</i>
<i>void</i>	<i>D.set_face_in_face_loop(Halfedge_handle h, Face_handle f)</i>	loops around the face incident to <i>h</i> and sets all face pointers to <i>f</i> . <i>Precondition: h != Halfedge_handle().</i>
<i>Halfedge_handle</i>	<i>D.flip_edge(Halfedge_handle h)</i>	performs an edge flip. It returns <i>h</i> after rotating the edge <i>h</i> one vertex in the direction of the face orientation. <i>Precondition: h != Halfedge_handle() and both incident faces of h are triangles.</i>

Modifying Functions (Primitives)

<i>void</i>	<i>D.set_vertex_halfedge(Vertex_handle v, Halfedge_handle g)</i>	sets the incident halfedge of <i>v</i> to <i>g</i> .
<i>void</i>	<i>D.set_vertex_halfedge(Halfedge_handle h)</i>	sets the incident halfedge of the vertex incident to <i>h</i> to <i>h</i> .
<i>void</i>	<i>D.set_vertex(Halfedge_handle h, Vertex_handle v)</i>	sets the incident vertex of <i>h</i> to <i>v</i> .
<i>void</i>	<i>D.set_prev(Halfedge_handle h, Halfedge_handle g)</i>	sets the previous link of <i>h</i> to <i>g</i> .
<i>void</i>	<i>D.set_face(Halfedge_handle h, Face_handle f)</i>	sets the incident face of <i>h</i> to <i>f</i> .
<i>void</i>	<i>D.set_face_halfedge(Face_handle f, Halfedge_handle g)</i>	sets the incident halfedge of <i>f</i> to <i>g</i> .
<i>void</i>	<i>D.set_face_halfedge(Halfedge_handle h)</i>	sets the incident halfedge of the face incident to <i>h</i> to <i>h</i> .

<i>CGAL::HalfedgeDS_decorator<HDS></i>	page 1827
<i>CGAL::HalfedgeDS_const_decorator<HDS></i>	page 1825

Example

The following program fragment illustrates how a refined halfedge class for a polyhedron can make use of the *find_prev()* member function to implement a *prev()* member function that works regardless of whether the halfedge data structure *HDS* provides a *prev()* member function for its halfedges or not. In the case that not, the implementation given here runs in time proportional to the size of the incident face. For const-correctness a second implementation with signature *Halfedge_const_handle prev() const;* is needed.

Note also the use of the static member function *halfedge_handle()* of the halfedge data structure. It converts a pointer to the halfedge into a halfedge handle. This conversion encapsulates possible adjustments for hidden data members in the true halfedge type, such as linked-list pointers.

```
struct Polyhedron_halfedge {  
    // ...  
    Halfedge_handle prev() {  
        CGAL::HalfedgeDS_items_decorator<HDS> decorator;  
        return decorator.find_prev( HDS::halfedge_handle(this));  
    }  
};
```

CGAL::HalfedgeDS_min_items

Definition

The class *HalfedgeDS_min_items* is a model of the *HalfedgeDSItems* concept. It defines types for vertices, halfedges, and faces that declare the minimal required incidences for a *HalfedgeDS*, which are the *next()* and the *opposite()* member function for halfedges.

```
#include <CGAL/HalfedgeDS_min_items.h>
```

Example

The following example shows the canonical implementation of the *CGAL::HalfedgeDS_min_items* class. It uses the base classes for the item types that are provided in the library.

```
struct HalfedgeDS_min_items {
    template < class Refs, class Traits>
    struct Vertex_wrapper {
        typedef CGAL::HalfedgeDS_vertex_min_base< Refs>    Vertex;
    };
    template < class Refs, class Traits>
    struct Halfedge_wrapper {
        typedef CGAL::HalfedgeDS_halfedge_min_base< Refs> Halfedge;
    };
    template < class Refs, class Traits>
    struct Face_wrapper {
        typedef CGAL::HalfedgeDS_face_min_base< Refs>      Face;
    };
};
```

CGAL::HalfedgeDS_list<Traits,HalfedgeDSItems,Alloc>

Definition

The class *HalfedgeDS_list*<Traits,HalfedgeDSItems,Alloc> is a model for the *HalfedgeDS* concept. *HalfedgeDS_list*<Traits,HalfedgeDSItems,Alloc> is a list-based representation with bidirectional iterators that supports removal.

```
#include <CGAL/HalfedgeDS_list.h>
```

Is Model for the Concepts

HalfedgeDS<Traits,Items,Alloc> page [1809](#)

Types

```
typedef bidirectional_iterator_tag    iterator_category;
typedef CGAL::Tag_true                Supports_removal;
```

Operations

Besides operations required from the concept *HalfedgeDS*<Traits,Items,Alloc>, this class supports additionally:

```
void    hds.vertices_splice( Vertex_iterator target, Self &source, Vertex_iterator first, Vertex_iterator last)
```

inserts elements in the range *[first, last)* before position *target* and removes the elements from *source*. It takes constant time if *&source == &hds*; otherwise, it takes linear time in the size of the range.

Precondition: *[first, last)* is a valid range in *source*. *target* is not in the range *[first, last)*.

```
void    hds.halfedges_splice( Halfedge_iterator target,
                             Self &source,
                             Halfedge_iterator first,
                             Halfedge_iterator last)
```

inserts elements in the range *[first, last)* before position *target* and removes the elements from *source*. It takes constant time if *&source == &hds*; otherwise, it takes linear time in the size of the range.

Precondition: *[first, last)* is a valid range in *source*. *target* is not in the range *[first, last)*.

```
void    hds.faces_splice( Face_iterator target, Self &source, Face_iterator first, Face_iterator last)
```

inserts elements in the range *[first, last)* before position *target* and removes the elements from *source*. It takes constant time if *&source == &hds*; otherwise, it takes linear time in the size of the range.

Precondition: *[first, last)* is a valid range in *source*. *target* is not in the range *[first, last)*.

Implementation

HalfedgeDS_list<Traits,HalfedgeDSItems,Alloc> uses internally the *CGAL::In_place_list* container class. The copy constructor and the assignment operator need $O(n)$ time with n the total number of vertices, halfedges, and faces. The former suboptimal implementation with an $O(n \log n)$ runtime has been replaced with a faster implementation based on hashing for the pointer lookup.

CGAL_ALLOCATOR(int) is used as default argument for the *Alloc* template parameter.

CGAL::HalfedgeDS_vector<Traits,HalfedgeDSItems,Alloc>

Definition

The class *HalfedgeDS_vector<Traits,HalfedgeDSItems,Alloc>* is a model for the *HalfedgeDS* concept. *HalfedgeDS_vector<Traits,HalfedgeDSItems,Alloc>* is a vector-based representation with random access iterators that does not support removal.

```
#include <CGAL/HalfedgeDS_vector.h>
```

Is Model for the Concepts

HalfedgeDS<Traits,Items,Alloc> page [1809](#)

Types

```
typedef random_access_iterator_tag    iterator_category;
typedef CGAL::Tag_false               Supports_removal;
```

CGAL::HalfedgeDS_const_decorator<HDS> page [1825](#)

Implementation

HalfedgeDS_vector<Traits,HalfedgeDSItems,Alloc> uses internally the STL *std::vector* container class. We require that we can create a *std::vector::iterator* from a pointer. If this will not be true any longer for any major STL distribution we might switch to an internal implementation of a vector.

The capacity is restricted to the reserved size. Allocations are not possible beyond the capacity without calling reserve again. All handles and iterators are invalidated upon a reserve call that increases the capacity.

CGAL_ALLOCATOR(int) is used as default argument for the *Alloc* template parameter.

CGAL::HalfedgeDS_vertex_base<Refs>

Definition

The class *HalfedgeDS_vertex_base<Refs>* is a model of the *HalfedgeDSVertex* concept. *Refs* is an instantiation of a *HalfedgeDS*. The template declaration of *HalfedgeDS_vertex_base<Refs>* has three parameters with some defaults that allow to select various flavors of vertices. The declaration is best explained with the two following declarations, essentially hiding an implementation dependent default setting:

```
template <class Refs, class T = CGAL::Tag_true>
class HalfedgeDS_vertex_base;
```

```
template <class Refs, class T, class Point>
class HalfedgeDS_vertex_base;
```

HalfedgeDS_vertex_base<Refs> defines a vertex including a reference to an incident halfedge.

CGAL::HalfedgeDS_vertex_base<Refs,CGAL::Tag_false> is a vertex without a reference to an incident halfedge. It is empty besides the required type definitions. It can be used for deriving own vertex implementations. See also *CGAL::HalfedgeDS_vertex_min_base<Refs>*.

CGAL::HalfedgeDS_vertex_base<Refs,CGAL::Tag_true,Point> is a vertex with a reference to an incident halfedge and it stores a point of type *Point*. It can be used as a vertex for a model of the *PolyhedronItems_3* concept.

CGAL::HalfedgeDS_vertex_base<Refs,CGAL::Tag_false,Point> is a vertex without a reference to an incident halfedge and it stores a point of type *Point*. It can be used as a vertex for a model of the *PolyhedronItems_3* concept.

```
#include <CGAL/HalfedgeDS_vertex_base.h>
```

27.1 Introduction

In solid modeling, two major representation schemes are used: *constructive solid geometry* (CSG) and *boundary representations* (B-rep). Both have inherent strengths and weaknesses, see [Hof89c] for a discussion.

In CSG a solid is represented as a set-theoretic boolean combination of primitive solid objects, such as blocks, prisms, cylinders, or toruses. The boolean operations are not evaluated, instead, objects are represented implicitly with a tree structure; leaves represent primitive objects and interior nodes represent boolean operations or rigid motions, e.g., translation and rotation. Algorithms on such a CSG-tree first evaluate properties on the primitive objects and propagate the results using the tree structure.

A B-rep describes the incidence structure and the geometric properties of all lower-dimensional features of the boundary of a solid. Surfaces are oriented to decide between the interior and exterior of a solid.

The class of representable objects in a CSG is usually limited by the choice of the primitive solids. A B-rep is usually limited by the choice for the geometry of the supporting curves for edges and the supporting surfaces for surface patches, and, in addition, the connectivity structure that is allowed. In particular, a B-rep is not always closed under boolean set operations. As an example, the class of orientable 2-manifold objects is a popular and well understood class of surfaces commonly used for B-reps. They can be represented and manipulated efficiently, the data structures are compact in storage size, and many algorithms are simple. On the other side, this object class is not closed under boolean set operations, as many examples can illustrate, such as the Figure shown above that can be generated using boolean set operations on cubes. The vertices bounding the tunnel, or the edge connecting the “roof” with the cube are non-manifold situations.

In our implementation of Nef polyhedra in 3D, we offer a B-rep data structure that is closed under boolean operations and with all their generality. Starting from halfspaces (and also directly from oriented 2-manifolds), we can work with set union, set intersection, set difference, set complement, interior, exterior, boundary, closure, and regularization operations (see Section 27.4 for an explanation of regularized set operations). In essence, we can evaluate a CSG-tree with halfspaces as primitives and convert it into a B-rep representation.

In fact, we work with two data structures; one that represents the local neighborhoods of vertices, which is in itself already a complete description, and a data structure that connects these neighborhoods up to a global data structure with edges, facets, and volumes. We offer a rich interface to investigate these data structures, their different elements and their connectivity. We provide affine (rigid) transformations and a point location query operation. We have a custom file format for storing and reading Nef polyhedra from files. We offer a simple OpenGL-based visualizer for debugging and illustrations.

27.2 Definition

The theory of Nef polyhedra has been developed for arbitrary dimensions. The class `CGAL::Nef_polyhedron_3` implements a boundary representation for the 3-dimensional case.

Definition: A *Nef-polyhedron* in dimension d is a point set $P \subseteq \mathbb{R}^d$ generated from a finite number of open halfspaces by set complement and set intersection operations.

Set union, difference and symmetric difference can be reduced to intersection and complement. Set complement changes between open and closed halfspaces, thus the topological operations *boundary*, *interior*, *exterior*, *closure* and *regularization* are also in the modeling space of Nef polyhedra.

A face of a Nef polyhedron is defined as an equivalence class of *local pyramids* that are a characterization of the local space around a point.

Definition: A point set $K \subseteq \mathbb{R}^d$ is called a *cone with apex 0*, if $K = \mathbb{R}^+ K$ (i.e., $\forall p \in K, \forall \lambda > 0 : \lambda p \in K$) and

it is called a *cone with apex* $x, x \in \mathbb{R}^d$, if $K = x + \mathbb{R}^+(K - x)$. A cone K is called a *pyramid* if K is a polyhedron.

Now let $P \in \mathbb{R}^d$ be a polyhedron and $x \in \mathbb{R}^d$. There is a neighborhood $U_0(x)$ of x such that the pyramid $Q := x + \mathbb{R}^+((P \cap U(x)) - x)$ is the same for all neighborhoods $U(x) \subseteq U_0(x)$. Q is called the *local pyramid* of P in x and denoted $\text{Pyr}_P(x)$.

Definition: Let $P \in \mathbb{R}^d$ be a polyhedron and $x, y \in \mathbb{R}^d$ be two points. We define an equivalence relation $x \sim y$ iff $\text{Pyr}_P(x) = \text{Pyr}_P(y)$. The equivalence classes of \sim are the *faces* of P . The dimension of a face s is the dimension of its affine hull, $\dim s := \dim \text{aff } s$.

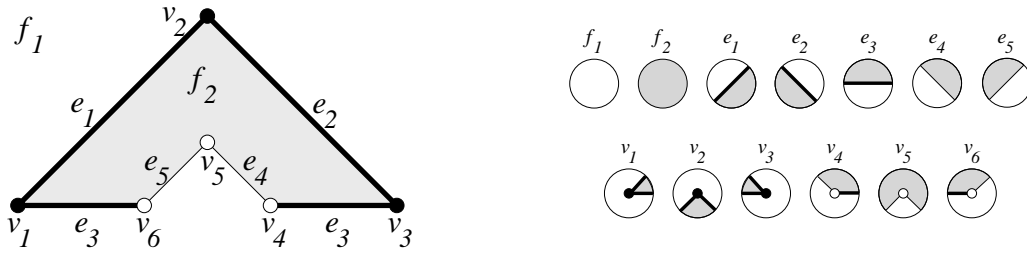

In other words, a *face* s of P is a maximal non-empty subset of \mathbb{R}^d such that all of its points have the same local pyramid Q denoted $\text{Pyr}_P(s)$. This definition of a face partitions \mathbb{R}^d into faces of different dimension. A face s is either a subset of P , or disjoint from P . We use this later in our data structure and store a selection mark in each face indicating its set membership.

Faces do not have to be connected. There are only two full-dimensional faces possible, one whose local pyramid is the space \mathbb{R}^d itself and the other with the empty set as a local pyramid. All lower-dimensional faces form the *boundary* of the polyhedron. As usual, we call zero-dimensional faces *vertices* and one-dimensional faces *edges*. In the case of polyhedra in space we call two-dimensional faces *facets* and the full-dimensional faces *volumes*. Faces are *relative open* sets, e.g., an edge does not contain its end-vertices.

We illustrate the definitions with an example in the plane. Given the closed halfspaces

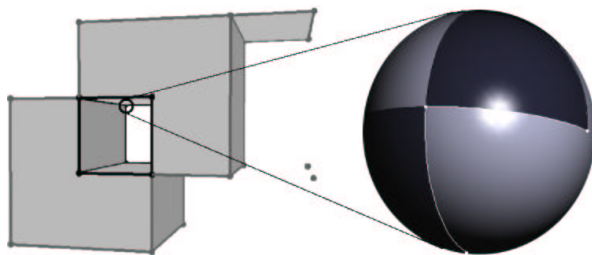

$$h_1 : y \geq 0, \quad h_2 : x - y \geq 0, \quad h_3 : x + y \leq 3, \quad h_4 : x - y \geq 1, \quad h_5 : x + y \leq 2,$$

we define our polyhedron $P := (h_1 \cap h_2 \cap h_3) - (h_4 \cap h_5)$.

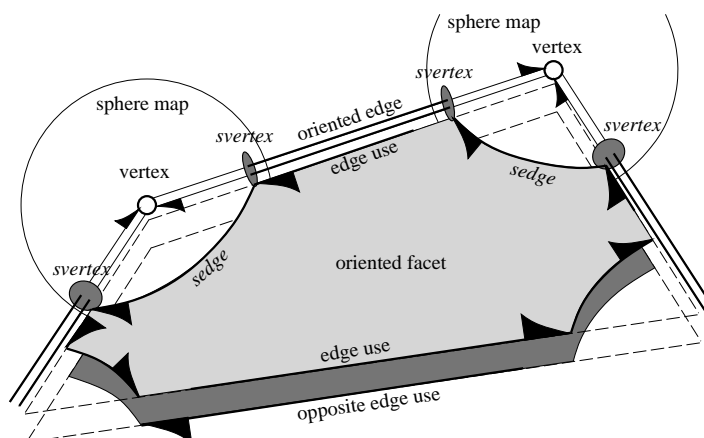

The left figure illustrates the polyhedron with its partially closed and partially open boundary, i.e., vertex v_4, v_5, v_6 , and edges e_4 and e_5 are not part of P . The local pyramids for the faces are $\text{Pyr}_P(f_1) = \emptyset$ and $\text{Pyr}_P(f_2) = \mathbb{R}^2$. Examples for the local pyramids of edges are the closed halfspace h_2 for the edge e_1 , $\text{Pyr}_P(e_1) = h_2$, and the open halfspace that is the complement of h_4 for the edge e_5 , $\text{Pyr}_P(e_5) = \{(x, y) | x - y < 1\}$. The edge e_3 consists actually of two disconnected parts, both with the same local pyramid $\text{Pyr}_P(e_3) = h_1$. In our data structure, we will represent the two connected components of the edge e_3 separately. The figure on the right lists all local pyramids for this example.

The local pyramids of each vertex are represented by conceptually intersecting the local neighborhood with a small ϵ -sphere. This intersection forms a planar map on the sphere (see next two figures), which together with the set-selection mark for each item (i.e. vertices, edges, loops and faces) forms a two-dimensional Nef polyhedron embedded in the sphere. We add the set-selection mark for the vertex and call the resulting structure the *sphere map* of the vertex. We use the prefix s to distinguish the elements of the sphere map from the three-dimensional elements. See Chapter 21 for further details.

Having sphere maps for all vertices of our polyhedron is a sufficient but not easily accessible representation of the polyhedron. We enrich the data structure with more explicit representations of all the faces and incidences between them.

We depart slightly from the definition of faces in a Nef polyhedron; we represent the connected components of a face individually and do not implement additional bookkeeping to recover the original faces (e.g., all edges on a common supporting line with the same local pyramid) as this is not needed in our algorithms. We discuss features in the increasing order of dimension.

edges: We store two oppositely oriented edges for each edge and have a pointer from one oriented edge to its opposite edge. Such an oriented edge can be identified with an *svertex* in a sphere map; it remains to link one *svertex* with the corresponding opposite *svertex* in the other sphere map.

edge uses: An edge can have many incident facets (non-manifold situation). We introduce two oppositely oriented edge-uses for each incident facet; one for each orientation of the facet. An edge-use points to its corresponding oriented edge and to its oriented facet. We can identify an edge-use with an oriented *sedge* in the sphere map, or, in the special case also with an *sloop*. Without mentioning it explicitly in the remainder, all references to *sedge* can also refer to *sloop*.

facets: We store oriented facets as boundary cycles of oriented edge-uses. We have a distinguished outer boundary cycle and several (or maybe none) inner boundary cycles representing holes in the facet. Boundary cycles are linked in one direction. We can access the other traversal direction when we switch to the oppositely oriented facet, i.e., by using the opposite edge-use.

shells: The volume boundary decomposes into different connected components, the *shells*. A shell consists of a connected set of facets, edges, and vertices incident to this volume. Facets around an edge form a radial order that is captured in the radial order of *sedges* around an *svertex* in the sphere map. Using this information, we can trace a shell from one entry element with a graph search. We offer this graph traversal (to the user) in a visitor design pattern.

volumes: A volume is defined by a set of shells, one outer shell containing the volume and several (or maybe none) inner shells separating voids which are excluded from the volume.

For each face we store a label, e.g., a set-selection mark, which indicates whether the face is part of the solid or if it is excluded. We call the resulting data structure *Selective Nef Complex*, *SNC* for short [GHH⁺03]. However, in CGAL we identify the names and call the *SNC* data structure *CGAL::Nef_polyhedron_3*.

27.3 Infimaximal Box

We call a Nef polyhedron *bounded* if its boundary is bounded, i.e., finite, and *unbounded* otherwise. Note that unbounded point sets can have a bounded boundary, for example, the complement of a cube has an unbounded outer volume, but its boundary remains bounded.

Using a boundary representation, it is convenient (conceptually and in our implementation) to consider bounded Nef polyhedra only. Bounded Nef polyhedra are also closed under boolean set operations. However, one needs to start with bounded primitives; the conceptually nice halfspaces cannot be used. Instead, we offer a construction from oriented 2-manifolds represented in a *CGAL::Polyhedron_3*, see Section 27.5.4 below.

In order to handle unbounded Nef polyhedra conceptually in the same way as we handle bounded Nef polyhedra, we intersect them with a bounding cubical volume of size $[-R, R]^3$, where R is a symbolical unspecified value, which is finite but larger than all coordinate values that may occur in the bounded part of the polyhedron. As a result, each Nef polyhedron becomes bounded. We call the boundary of the bounding volume the *infimaximal box* [SM00].

We clip lines and rays at the infimaximal box. The intersection points with the infimaximal box are called *non-standard points*, which are points whose coordinates are $-R$ or R in at least one dimension, and linear functions $f(R)$ for the other dimensions. Such extended points (and developed from there also extended segments etc) are provided in CGAL with extended kernels—*CGAL::Extended_cartesian* and *CGAL::Extended_homogeneous*. They are regular CGAL kernels with a polynomial type as coordinate number type.

As long as an extended kernel is used, the full functionality provided by the *CGAL::Nef_polyhedron_3* class is available. If a kernel that does not use polynomials to represent coordinates is used, it is not possible to create or load unbounded Nef polyhedra, but all other operations work as expected. We provided both possibilities, since the restriction to bounded Nef polyhedra improves considerably space requirements (plain number type instead of polynomial), and runtime performance.

27.4 Regularized Set Operations

Since manifolds are not closed under boolean operations, Requicha proposes to use *regularized set operations* [KM76, Req80]. A set is *regular*, if it equals the closure of its interior. A regularized set operation is defined as the standard set operation followed by a regularization of the result. Regularized sets are closed under regularized set operations.

Regularized set operations are important since they simplify the class of solids to exclude lower dimensional features and the boundary belongs to the point set. These properties are considered to reflect the nature of physical solids more closely.

Regularized polyhedral sets are a subclass of Nef polyhedra. We provide the *regularization* operation as a shortcut for the consecutive execution of the *interior* and the *closure* operations.

27.5 Example Programs

The following example gives a first impression of how to instantiate and use *Nef_polyhedron_3*. We use the *CGAL::Cartesian* kernel. All Cartesian and homogeneous kernels of CGAL are suitable if the number type parameter follows the usual requirements of being a model of the *CGAL::FieldNumberType* concept for the Cartesian kernels, or the *CGAL::RingNumberType* concept for the homogeneous kernels, respectively. Note however, that in the current state, the Nef polyhedron works only with CGAL kernels. The implementation makes use of CGAL specific functions in kernel objects, and does not yet offer a designed interface to a clean kernel concept that could be offered by an external kernel as well.

The example creates two Nef polyhedra—*N0* is the empty set, while *N1* represents the full space, i.e., the set of all points in the 3-dimensional space. The assertion assures that the empty set is the complement of the full space.

```
#include <CGAL/Gmpz.h>
#include <CGAL/Homogeneous.h>
#include <CGAL/Nef_polyhedron_3.h>

typedef CGAL::Homogeneous<CGAL::Gmpz> Kernel;
typedef CGAL::Nef_polyhedron_3<Kernel> Nef_polyhedron;

int main() {
    Nef_polyhedron N0(Nef_polyhedron::EMPTY);
    Nef_polyhedron N1(Nef_polyhedron::COMPLETE);

    CGAL_assertion (N0 == N1.complement());
    return 0;
}
```

File: examples/Nef_3/nef_3_simple.cpp

27.5.1 Construction and Comparison

This example shows the various constructors. We can create the empty set, which is also the default constructor, and the full space, i.e. all points of \mathbb{R}^3 belong to the polyhedron. We can create a halfspace defined by a plane bounding it. It is only available if an extended kernel is used. The halfspace constructor has a second parameter that specifies whether the defining plane belongs to the point set (*Nef_polyhedron::INCLUDED*) or not (*Nef_polyhedron::EXCLUDED*). The default value is *Nef_polyhedron::INCLUDED*. Additionally, we can create a *Nef_polyhedron_3* from a *Polyhedron_3*, see the Section 27.5.4 below.

We can compute the point sets of two Nef polyhedra for equality and proper subset relationships. We offer the usual comparison operators `==`, `!=`, `<=`, `>=`, `<` and `>`.

Nef polyhedra have the important feature that a representation that is called the *reduced Würzburg structure* is unique, i.e., two point sets of Nef polyhedra are equal if and only if the representations are equal. The proof for the reduced Würzburg structure carries over to our representation and the comparison operators are therefore trivial to implement.

```
#include <CGAL/Gmpz.h>
#include <CGAL/Extended_homogeneous.h>
#include <CGAL/Nef_polyhedron_3.h>
```

```

27.5.2 Point Set Operations

As explained in the introduction, Nef polyhedra are closed under all boolean set operations. The class *Nef_polyhedron_3* provides functions and operators for the most common ones: complement (*operator!*), union (*operator+*), difference (*operator-*), intersection (*operator**) and symmetric difference (*operator^*). Additionally, the operators **=*, *-=*, **=* and *^=* are defined.

Nef_polyhedron_3 also provides the topological operations *interior()*, *closure()* and *boundary()*. With *interior()* one deselects all boundary items, with *boundary()* one deselects all volumes, and with *closure()* one selects all boundary items.

```

#include <CGAL/Gmpz.h>
#include <CGAL/Extended_homogeneous.h>
#include <CGAL/Nef_polyhedron_3.h>

typedef CGAL::Extended_homogeneous<CGAL::Gmpz> Kernel;
typedef CGAL::Nef_polyhedron_3<Kernel> Nef_polyhedron;
typedef Kernel::Plane_3 Plane_3;

int main() {

```

```

Nef_polyhedron N1(Plane_3( 1, 0, 0,-1));
Nef_polyhedron N2(Plane_3(-1, 0, 0,-1));
Nef_polyhedron N3(Plane_3( 0, 1, 0,-1));
Nef_polyhedron N4(Plane_3( 0,-1, 0,-1));
Nef_polyhedron N5(Plane_3( 0, 0, 1,-1));
Nef_polyhedron N6(Plane_3( 0, 0,-1,-1));

Nef_polyhedron I1(!N1 + !N2); // open slice in yz-plane
Nef_polyhedron I2(N3 - !N4); // closed slice in xz-plane
Nef_polyhedron I3(N5 ^ N6); // open slice in yz-plane
Nef_polyhedron Cube1(I2 * !I1);
Cube1 *= !I3;
Nef_polyhedron Cube2 = N1 * N2 * N3 * N4 * N5 * N6;

CGAL_assertion(Cube1 == Cube2); // both are closed cube
CGAL_assertion(Cube1 == Cube1.closure());
CGAL_assertion(Cube1 == Cube1.regularization());
CGAL_assertion((N1 - N1.boundary()) == N1.interior());
CGAL_assertion(I1.closure() ==
    I1.complement().interior().complement());
CGAL_assertion(I1.regularization() == I1.interior().closure());
return 0;
}

```

File: examples/Nef_3/point_set_operations.cpp

27.5.3 Transformation

Using the `std::transform` function, a Nef polyhedron can be translated, rotated and scaled. The usage is shown in the following example:

```

#include <CGAL/Gmpz.h>
#include <CGAL/Extended_homogeneous.h>
#include <CGAL/Nef_polyhedron_3.h>
#include <CGAL/IO/Nef_polyhedron_istream_3.h>

//instead of
//typedef CGAL::Extended_homogeneous<CGAL::Gmpz> Kernel;
// workaround for VC++
struct Kernel : public CGAL::Extended_homogeneous<CGAL::Gmpz> {};

typedef CGAL::Nef_polyhedron_3<Kernel> Nef_polyhedron;
typedef Nef_polyhedron::Plane_3 Plane_3;
typedef Nef_polyhedron::Vector_3 Vector_3;
typedef Nef_polyhedron::Aff_transformation_3 Aff_transformation_3;

int main() {

    Nef_polyhedron N(Plane_3(0,1,0,0));
    Aff_transformation_3 transl(CGAL::TRANSLATION, Vector_3(5, 7, 9));
    Aff_transformation_3 rotx90(1,0,0,

```

```

                                0, 0, -1,
                                0, 1, 0,
                                1);
Aff_transformation_3 scale(3, 0, 0,
                            0, 3, 0,
                            0, 0, 3,
                            2);

N.transform(transl);
CGAL_assertion(N == Nef_polyhedron(Plane_3(0, 1, 0, -7)));
N.transform(rotx90);
CGAL_assertion(N == Nef_polyhedron(Plane_3(0, 0, 1, -7)));
N.transform(scale);
CGAL_assertion(N == Nef_polyhedron(Plane_3(0, 0, 2, -21)));

return 0;
}

```

File: examples/Nef_3/transformation.cpp

27.5.4 The Interface between Polyhedron_3 and Nef_polyhedron_3

Nef_polyhedron_3 provides an interface for the conversion between polyhedral surfaces represented with the *CGAL::Polyhedron_3* class and *Nef_polyhedron_3*. *Polyhedron_3* represents orientable 2-manifold objects with boundaries. However, we exclude surfaces with boundaries from the conversion to *Nef_polyhedron_3* since they have no properly defined volume.

Both conversion directions can only be performed if the boundary of the point set is an oriented closed 2-manifold. *Nef_polyhedron_3* provides the function *is_simple()* and *Polyhedron_3* provides the function *is_closed()* to test for this property. The usage is illustrated by the example program below.

The conversion gives us the possibility to use several file formats. *Polyhedron_3* can read the (.off) file format and can write the (.off), OpenInventor (.iv), VRML 1.0 and 2.0 (.wrl) and Wavefront Advanced Visualizer object format (.obj), see Section 25.4.

```

#include <CGAL/Gmpz.h>
#include <CGAL/Homogeneous.h>
#include <CGAL/Polyhedron_3.h>
#include <CGAL/IO/Polyhedron_iostream.h>
#include <CGAL/Nef_polyhedron_3.h>
#include <CGAL/IO/Nef_polyhedron_iostream_3.h>
#include <iostream>

typedef CGAL::Homogeneous<CGAL::Gmpz> Kernel;
typedef CGAL::Polyhedron_3<Kernel> Polyhedron;
typedef CGAL::Nef_polyhedron_3<Kernel> Nef_polyhedron;
typedef Kernel::Vector_3 Vector_3;
typedef Kernel::Aff_transformation_3 Aff_transformation_3;

int main() {
    Polyhedron P;
    std::cin >> P;
}

```

```

if(P.is_closed()) {
    Nef_polyhedron N1(P);
    Nef_polyhedron N2(N1);
    Aff_transformation_3 aff(CGAL::TRANSLATION, Vector_3(2,2,0,1));
    N2.transform(aff);
    N1 += N2;

    if(N1.is_simple()) {
        N1.convert_to_polyhedron(P);
        std::cout << P;
    }
    else
        std::cerr << "N1 is not a 2-manifold." << std::endl;
}
}

```

File: examples/Nef_3/interface_polyhedron.cpp

27.5.5 Using an Extended Kernel

The provided extended kernels are used the same way as any other CGAL kernel. The essential difference is, that coordinates are not represented by the number type that was used to parameterize the kernel type, but by a *Nef_polynomial* parametrized by that number type.

The example iterates all vertices of a given Nef polyhedron and decides whether it is an standard vertex or a vertex on the infimal box. Furthermore, it tests whether any of the vertices is at (R,R,R) . Recall that R was the symbolical value, large but finite, for the size of the infimal box.

```

#include <CGAL/Gmpz.h>
#include <CGAL/Extended_homogeneous.h>
#include <CGAL/Nef_polyhedron_3.h>
#include <CGAL/IO/Nef_polyhedron_istream_3.h>

typedef CGAL::Gmpz NT;
//instead of
//typedef CGAL::Extended_homogeneous<NT> Kernel;
// workaround for VC++
struct Kernel : public CGAL::Extended_homogeneous<NT> {};

typedef CGAL::Nef_polyhedron_3<Kernel> Nef_polyhedron;
typedef Nef_polyhedron::RT RT;
typedef Nef_polyhedron::Point_3 Point_3;
typedef Nef_polyhedron::Plane_3 Plane_3;
typedef Nef_polyhedron::Vertex_const_iterator Vertex_const_iterator;

int main() {

    Nef_polyhedron N;
    std::cin >> N;

    Vertex_const_iterator v;
    for(v = N.vertices_begin(); v != N.vertices_end(); ++v) {

```

```

Point_3 p(v->point());
if(p.hx().degree() > 0 || p.hy().degree() > 0 || p.hz().degree() > 0)
    std::cout << "extended vertex at " << p << std::endl;
else
    std::cout << "standard vertex at " << p << std::endl;

if(p == Point_3(RT(0,1), RT(0,1), RT(0,1)))
    std::cout << " found vertex (right,back,top) of the infimaximal
box"
                << std::endl;
}

return 0;
}

```

File: examples/Nef_3/extended_kernel.cpp

27.6 File I/O

Nef_polyhedron_3 provides an input and an output operator for a proprietary file format. It includes the complete incidence structure, the geometric data, and the marks of each item. The output depends on the output operators of the geometric primitives provided by the traits class, and on the output operators of the used number type. Therefore, it is necessary to use the same kernel and the same number type for input and output operations.

We recommend the use of the CGAL kernels *Homogeneous*, *Exact_predicates_exact_constructions_kernel*, or *Extended_homogeneous*. The Homogeneous kernel provides reliable fast performance. In combination with *leda_integer* it is the fastest kernel for *Nef_polyhedron_3*. The *Exact_predicates_exact_constructions_kernel* uses filtering. In non-degenerate scenarios it's faster than the *Homogeneous* kernel. The most important advantage of the filtered kernel is that it is a Cartesian kernel, which allows the proper handling of OFF files using floating-point coordinates.

For effective filtering we had to change some concepts. The new concepts must be activated by using the *SNC_indexed_items*, because they don't apply for the extended kernels, yet. The new concepts also speed up *Nef_polyhedron_3* also in combination with all other standard kernels. The following example illustrates their usage.

```

#include <CGAL/Exact_predicates_exact_constructions_kernel.h>
#include <CGAL/Polyhedron_3.h>
#include <CGAL/IO/Polyhedron_iostream.h>
#include <CGAL/Nef_polyhedron_3.h>
#include <CGAL/IO/Nef_polyhedron_iostream_3.h>

typedef CGAL::Exact_predicates_exact_constructions_kernel Kernel;
typedef CGAL::Polyhedron_3<Kernel> Polyhedron;
typedef CGAL::Nef_polyhedron_3<Kernel> Nef_polyhedron;

int main() {

    Polyhedron P;
    std::cin >> P;
    Nef_polyhedron N(P);
}

```

```

std::cout << "Exact_predicates_exact_constructions_kernel +
SNC_indexed_items"
          << std::endl
          << "  allows efficient handling of input "
          << "    using floating point coordinates"
          << std::endl;

if(N.is_simple()) {
    N.convert_to_polyhedron(P);
    std::cout << P;
}
else {
    std::cout << N;
}
}

```

File: examples/Nef_3/handling_double_coordinates.cpp

We provide compatibility between the input and output of various kernels. For most of the CGAL kernels it is possible to write a file constructed with one kernel and reread it with another. Also, it is possible to write a bounded Nef polyhedron using the *Extended_homogeneous* kernel and to read it afterwards using a standard kernel.

```

#include <CGAL/Gmpz.h>
#include <CGAL/Homogeneous.h>
#include <CGAL/Extended_homogeneous.h>
#include <CGAL/Nef_polyhedron_3.h>
#include <CGAL/IO/Nef_polyhedron_iostream_3.h>
#include <fstream>

typedef CGAL::Gmpz NT;
typedef CGAL::Homogeneous<NT> SK;
typedef CGAL::Extended_homogeneous<NT> EK;
typedef CGAL::Nef_polyhedron_3<SK> Nef_polyhedron_S;
typedef CGAL::Nef_polyhedron_3<EK> Nef_polyhedron_E;

int main() {
    Nef_polyhedron_E E;
    Nef_polyhedron_S S;

    std::cin >> E;

    if(E.is_bounded()) {
        std::ofstream out("temp.nef3");
        out << E;
        std::ifstream in("temp.nef3");
        in >> S;
    }
}

```

File: examples/Nef_3/nefIO.cpp

27.7 Further Example Programs

27.7.1 Exploring a Sphere Map

A sphere map is explored by using the function `get_sphere_map`, which returns the sphere map of the specified vertex as a `Nef_polyhedron_S2`. `Nef_polyhedron_S2` provides the functionality necessary for the exploration. Note, that one has to use the type `Nef_polyhedron_S2` as specified in `Nef_polyhedron_3` as is shown in the following example.

```
#include <CGAL/Gmpz.h>
#include <CGAL/Homogeneous.h>
#include <CGAL/Nef_polyhedron_3.h>
#include <CGAL/IO/Nef_polyhedron_iostream_3.h>

typedef CGAL::Homogeneous<CGAL::Gmpz> Kernel;
typedef CGAL::Nef_polyhedron_3<Kernel> Nef_polyhedron_3;

int main() {

    // We've put the typedefs here as VC7 gives us an ICE if they are
    // global typedefs
    typedef Nef_polyhedron_3::Vertex_const_iterator Vertex_const_iterator;
    typedef Nef_polyhedron_3::Nef_polyhedron_S2 Nef_polyhedron_S2;
    typedef Nef_polyhedron_S2::SVertex_const_handle SVertex_const_handle;
    typedef Nef_polyhedron_S2::SHalfedge_const_handle
        SHalfedge_const_handle;
    typedef Nef_polyhedron_S2::SHalfloop_const_handle
        SHalfloop_const_handle;
    typedef Nef_polyhedron_S2::SFace_const_iterator SFace_const_iterator;
    typedef Nef_polyhedron_S2::SFace_cycle_const_iterator
        SFace_cycle_const_iterator;

    Nef_polyhedron_3 N;
    std::cin >> N;

    Vertex_const_iterator v = N.vertices_begin();
    Nef_polyhedron_S2 S(N.get_sphere_map(v));

    int i=0;
    SFace_const_iterator sf;
    for(sf = S.sfaces_begin(); sf != S.sfaces_end(); sf++) {
        SFace_cycle_const_iterator it;
        std::cout << "the sface cycles of sface " << i++ << " start with
an\n";
        for(it = sf->sface_cycles_begin(); it != sf->sface_cycles_end();
it++) {
            if (it.is_svertex())
                std::cout << " svertex at position "
                    << SVertex_const_handle(it)->point() << std::endl;
            else if (it.is_shalfedge())
                std::cout << " shalfedge from "
                    << SHalfedge_const_handle(it)->source()->point() << "
```

```

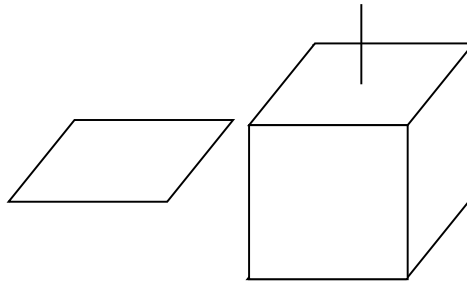

to "
    << SHalfedge_const_handle(it)->target()->point() <<
std::endl;
else if (it.is_shalfloop())
    std::cout << " shalfloop lying in the plane "
    << SHalfloop_const_handle(it)->circle() << std::endl;
    // other cases can not occur.
}
}
return 0;
}

```

File: examples/Nef_3/exploration_SM.cpp

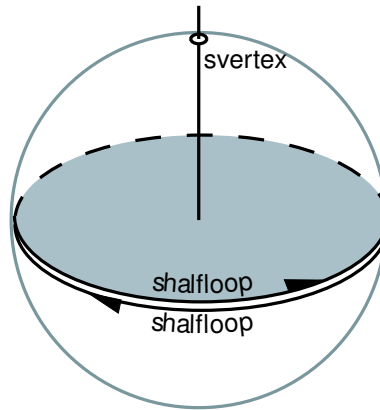

27.7.2 Exploring Shells

A *shell* of a Nef polyhedron is the connected part of the surface incident to a certain volume. Each halffacet, sface and shalfedge belongs to a single shell. The figure below illustrates the notion of a shell. It shows a Nef polyhedron with two volumes and three shells.

The first volume is the outer volume and the second volume is the interior of the cube. The first shell is the whole surface of the left object. The second shell is the outer surface of the right object, and the third shell is the inner surface of the right object.

In detail, the first shell consists of two halffacets, eight halfedges and four vertices. The second shell consists of the eight vertices of the cube plus the two endpoints of the antenna, all halffacets oriented outwards, and all halfedges. The third shell consists of the same eight vertices of the cube, plus the endpoint of the antenna that is in contact with the cube, all halffacets oriented inwards, and all halfedges (the same as for the second shell).

We discuss how sfaces, shalfedges, and sloops belong to the shells with a closeup view of the situation at the antenna foot. As you can see, there are three items on the sphere map - a shalfloop for each halfacet which intersects the sphere, and an svertex where the antenna intersects the sphere. The upper shalfloop lies on the halfacet which is oriented outwards and is therefore also oriented outwards. This shalfloop and the svertex belong to the second shell. The other shalfloop lies on the inwards oriented halfacet and is oriented inwards, too. This shalfloop belongs to the third shell.

Nef_polyhedron_3 offers a visitor interface to explore a shell following the well-known visitor pattern [GHJV95]. The interface is illustrated by the following example.

```
#include <CGAL/Gmpz.h>
#include <CGAL/Homogeneous.h>
#include <CGAL/Nef_polyhedron_3.h>
#include <CGAL/IO/Nef_polyhedron_iostream_3.h>

typedef CGAL::Homogeneous<CGAL::Gmpz> Kernel;
typedef CGAL::Nef_polyhedron_3<Kernel> Nef_polyhedron;
typedef Nef_polyhedron::Vertex_const_handle Vertex_const_handle;
typedef Nef_polyhedron::Halfedge_const_handle Halfedge_const_handle;
typedef Nef_polyhedron::Halfacet_const_handle Halfacet_const_handle;
typedef Nef_polyhedron::SHalfedge_const_handle SHalfedge_const_handle;
typedef Nef_polyhedron::SHalfloop_const_handle SHalfloop_const_handle;
typedef Nef_polyhedron::SFace_const_handle SFace_const_handle;
typedef Nef_polyhedron::Volume_const_iterator Volume_const_iterator;
typedef Nef_polyhedron::Shell_entry_const_iterator
    Shell_entry_const_iterator;
typedef Kernel::Point_3 Point_3;

class Shell_explorer {
    bool first;
    const Nef_polyhedron& N;
    Vertex_const_handle v_min;

public:
    Shell_explorer(const Nef_polyhedron& N_)
        : first(true), N(N_) {}

    void visit(Vertex_const_handle v) {
        if(first ||
            CGAL::lexicographically_xyz_smaller(v->point(), v_min->point())) {
            v_min = v;
        }
    }
};
```

```

        first=false;
    }
}

void visit(Halfedge_const_handle ) {}
void visit(Halffacet_const_handle ) {}
void visit(SHalfedge_const_handle ) {}
void visit(SHalfloop_const_handle ) {}
void visit(SFace_const_handle ) {}

Vertex_const_handle& minimal_vertex() { return v_min; }
void reset_minimal_vertex() { first = true; }
};

int main() {
    Nef_polyhedron N;
    std::cin >> N;

    int ic = 0;
    Volume_const_iterator c;
    Shell_explorer SE(N);
    CGAL_forall_volumes(c,N) {
        std::cout << "Volume " << ic++ << std::endl;
        int is = 0;
        Shell_entry_const_iterator it;
        CGAL_forall_shells_of(it,c) {
            SE.reset_minimal_vertex();
            N.visit_shell_objects(SFace_const_handle(it), SE);
            Point_3 p(SE.minimal_vertex()->point());
            std::cout << "  minimal vertex of shell " << is++
                        << " is at " << p << std::endl;
        }
    }
}

```

File: examples/Nef_3/shell_exploration.cpp

The function `visit_shell_objects(SFace_const_handle sf, Visitor& V)` explores a shell starting at the `sf`. The second argument expects any class providing the (possibly empty) functions `visit(Vertex_const_handle)`, `visit(Halfedge_const_handle)` (remember that `Halfedge` is the same type as `SVertex`), `visit(Halffacet_const_handle)`, `visit(SHalfedge_const_handle)`, `visit(SHalfloop_const_handle)` and `visit(SFace_const_handle)`. The `visit_shell_objects` function will call `visit` for each item belonging to the shell once. There are no further requirements on that class.

In the example, the class `Shell_explorer` is passed as second argument to `visit_shell_objects`. Its task is to find the lexicographically smallest vertex of a shell. Its internal state consists of three variables. The first one is a reference to the explored Nef polyhedron. This reference is often necessary to retrieve information from the Nef polyhedron. The second variable `v_min` stores the smallest vertex found so far, and the third variable `first` is initialized to `false` to signal that no vertex has been visited so far. After the first vertex has been visited `first` is changed to `true`.

`Shell_explorer` provides further member functions. After the exploration of a shell the `minimal_vertex` function retrieves the smallest vertex. The `reset_minimal_vertex` function allows one to use the same instance of

Shell_explorer on multiple shells. In this case, the *reset_minimal_vertex* function has to be called between the exploration of two shells.

The example program uses the *Shell_explorer* for each shell of the given Nef polyhedron once and reports the smallest vertex of each shell to the standard output.

27.7.3 Point Location

The *locate(Point_3 p)* function locates the point *p* in the Nef polyhedron and returns the item the point belongs to. The *locate* function returns an instance of *Object_handle*, which is a polymorphic handle type representing any handle type, no matter if it is mutable or const. For further usage of the result, the *Object_handle* has to be casted to the concrete handle type. The *CGAL::assign* function performs such a cast. It returns a boolean that reports the success or the failure of the cast. Looking at the possible return values of the *locate* function, the *Object_handle* can represent a *Vertex_const_handle*, a *Halfedge_const_handle*, a *Halffacet_handle*, or a *Volume_const_handle*. One of the four casts will succeed.

```
#include <CGAL/Gmpz.h>
#include <CGAL/Homogeneous.h>
#include <CGAL/Nef_polyhedron_3.h>
#include <CGAL/IO/Nef_polyhedron_istream_3.h>

typedef CGAL::Homogeneous<CGAL::Gmpz> Kernel;
typedef CGAL::Nef_polyhedron_3<Kernel> Nef_polyhedron_3;
typedef Kernel::Point_3 Point_3;

int main() {
    //We've put the typedefs here as VC7 gives us an ICE if they are global
    typedefs
    typedef Nef_polyhedron_3::Vertex_const_handle Vertex_const_handle;
    typedef Nef_polyhedron_3::Halfedge_const_handle Halfedge_const_handle;
    typedef Nef_polyhedron_3::Halffacet_const_handle
        Halffacet_const_handle;
    typedef Nef_polyhedron_3::Volume_const_handle Volume_const_handle;
    typedef Nef_polyhedron_3::Object_handle Object_handle;

    Nef_polyhedron_3 N;
    std::cin >> N;

    Vertex_const_handle v;
    Halfedge_const_handle e;
    Halffacet_const_handle f;
    Volume_const_handle c;
    Object_handle o = N.locate(Point_3(0,0,0));
    if(CGAL::assign(v,o))
        std::cout << "Locating vertex" << std::endl;
    else if(CGAL::assign(e,o))
        std::cout << "Locating edge" << std::endl;
    else if(CGAL::assign(f,o))
        std::cout << "Locating facet" << std::endl;
    else if(CGAL::assign(c,o))
        std::cout << "Locating volume" << std::endl;
    //other cases can not occur
}
```

```

    return 0;
}

```

File: examples/Nef_3/nef_3_point_location.cpp

27.8 Visualization

With the *Qt_widget_OpenGL* class an interface to OpenGL visualization via Qt is offered. The class knows how to handle mouse movements and clicks and how to move and scale the 3D object displayed in the widget. *Qt_widget_OpenGL* is a basis for writing Qt widgets displaying 3D objects. A user can derive a new class from *Qt_widget_OpenGL* which implements the drawing method and configures the context menus.

27.8.1 Visualizing a 3D Nef polyhedron

Qt_widget_Nef_3 implements the drawing methods for displaying instances of *Nef_polyhedron_3*. The following example shows how to set up an QApplication with a main widget of type *Qt_widget_Nef_3* and how to start the viewer.

```

#include <CGAL/basic.h>
#include <CGAL/Gmpz.h>
#include <CGAL/Homogeneous.h>
#include <CGAL/Nef_polyhedron_3.h>
#include <CGAL/IO/Nef_polyhedron_iostream_3.h>
#include <CGAL/IO/Qt_widget_Nef_3.h>
#include <qapplication.h>

typedef CGAL::Homogeneous<CGAL::Gmpz> Kernel;
typedef CGAL::Nef_polyhedron_3<Kernel> Nef_polyhedron_3;

int main(int argc, char* argv[]) {
    Nef_polyhedron_3 N;
    std::cin >> N;
}

```

```

File: demo/Nef_3/visualization_SNC.cpp

27.8.2 Visualizing a Sphere Map

Qt_widget_Nef_S2 is a widget implemented on the basis of *Qt_widget_OpenGL*. It can be used to visualize the sphere map of a vertex in a *Nef_polyhedron_3* using the interface between *Nef_polyhedron_S2* and *Nef_polyhedron_3*.

```

#include <CGAL/basic.h>
#include <CGAL/Gmpz.h>
#include <CGAL/Homogeneous.h>
#include <CGAL/Nef_polyhedron_3.h>
#include <CGAL/IO/Nef_polyhedron_iostream_3.h>
#include <CGAL/IO/Qt_widget_Nef_S2.h>
#include <qapplication.h>

typedef CGAL::Homogeneous<CGAL::Gmpz> Kernel;
typedef CGAL::Nef_polyhedron_3<Kernel> Nef_polyhedron_3;

int main(int argc, char* argv[]) {

    // We've put the typedefs here as VC7 gives us an ICE if they are
    // global typedefs
    typedef Nef_polyhedron_3::Vertex_const_iterator Vertex_const_iterator;
    typedef Nef_polyhedron_3::Nef_polyhedron_S2 Nef_polyhedron_S2;

    Nef_polyhedron_3 N;
    std::cin >> N;
    Vertex_const_iterator v = N.vertices_begin();
    Nef_polyhedron_S2 S(N.get_sphere_map(v));

    QApplication a(argc, argv);
    CGAL::Qt_widget_Nef_S2<Nef_polyhedron_S2>* w =
        new CGAL::Qt_widget_Nef_S2<Nef_polyhedron_S2>(S);
    a.setMainWidget(w);
    w->show();
    return a.exec();
}

```

3D Boolean Operations on Nef Polyhedra Reference Manual

Peter Hachenberger, Lutz Kettner, and Michael Seel

A Nef polyhedron is any point set generated from a finite number of open halfspaces by set complement and set intersection operations. In our implementation of Nef polyhedra in 3-dimensional space, we offer a B-rep data structures that is closed under boolean operations and with all their generality. Starting from halfspaces (and also directly from oriented 2-manifolds), we can work with set union, set intersection, set difference, set complement, interior, exterior, boundary, closure, and regularization operations. In essence, we can evaluate a CSG-tree with halfspaces as primitives and convert it into a B-rep representation.

In fact, we work with two data structures; one that represents the local neighborhoods of vertices, which is in itself already a complete description, and a data structure that connects these neighborhoods up to a global data structure with edges, facets, and volumes. We offer a rich interface to investigate these data structures, their different elements and their connectivity. We provide affine (rigid) transformations and a point location query operation. We have a custom file format for storing and reading Nef polyhedra from files. We offer a simple OpenGL visualization for debugging and illustrations.

CGAL::Nef_polyhedron_3<Traits>

Definition

A 3D Nef polyhedron is a subset of the 3-dimensional space that is the result of forming complements and intersections starting from a finite set H of 3-dimensional halfspaces. Nef polyhedra are closed under all binary set operations, i.e., intersection, union, difference, complement, and under the topological operations boundary, closure, and interior.

A 3D Nef polyhedron can be represented by the local pyramids of the minimal elements of its incidence structure. Without going into too much detail, a local pyramid essentially reflects the topologic and geometric situation at a certain location in a point set. For finite polyhedra the minimal elements of the incidence structure are vertices only. This means, that it suffices to model the topological and geometric situation of the vertices. For 3D Nef polyhedra, the local pyramid of a vertex is represented by a planar Nef polyhedra embedded on a sphere.

A *Nef_polyhedron_3* consists of vertices V , a sphere map for each vertex in V , edges E , facets F , volumes C , a mark for every item, and an incidence relation on them. Each edge and each facet is represented by two halfedges or two halffacets, respectively.

```
#include <CGAL/Nef_polyhedron_3.h>
```

Parameters

```
template < class Nef_polyhedronTraits_3,
           class Nef_polyhedronItems_3 = CGAL::Default_items<Nef_polyhedronTraits_3>,
           class Nef_polyhedronMarks = bool >
class Nef_polyhedron_3;
```

The first parameter requires one of the following exact kernels: *Homogeneous*, *Simple_homogeneous*, *Extended_homogeneous* parametrized with *Gmpz*, *leda_integer* or any other number type modeling \mathbb{Z} , or *Cartesian*, *Simple_cartesian*, *Extended_cartesian* parametrized with *Gmpq*, *leda_rational*, *Quotient<Gmpz>* or any other number type modeling \mathbb{Q} .

The second parameter and the third parameter are for future considerations. Neither *Nef_polyhedronItems_3* nor *Nef_polyhedronMarks* is specified, yet. Do not use any other than the default types for these two template parameters.

Types

<i>Nef_polyhedron_3<Traits>:: Traits</i>	traits class selected for <i>Nef_polyhedronTraits_3</i> .
<i>Nef_polyhedron_3<Traits>:: Mark</i>	All object (vertices, edges, etc.) are attributed by a Mark. Mark equals bool.
<i>Nef_polyhedron_3<Traits>:: size_type</i>	size type of <i>Nef_polyhedron_3</i> .
<i>Nef_polyhedron_3<Traits>:: Vertex_const_handle</i>	non-mutable handle to a vertex.
<i>Nef_polyhedron_3<Traits>:: Halfedge_const_handle</i>	non-mutable handle to a halfedge.
<i>Nef_polyhedron_3<Traits>:: Halffacet_const_handle</i>	non-mutable handle to a halffacet.

<i>Nef_polyhedron_3<Traits>:: Volume_const_handle</i>	non-mutable handle to a volume.
<i>Nef_polyhedron_3<Traits>:: SVertex_const_handle</i>	non-mutable handle to a svertex.
<i>Nef_polyhedron_3<Traits>:: SHalfedge_const_handle</i>	non-mutable handle to a shalfedge.
<i>Nef_polyhedron_3<Traits>:: SHalfloop_const_handle</i>	non-mutable handle to a shalfloop.
<i>Nef_polyhedron_3<Traits>:: SFace_const_handle</i>	non-mutable handle to a sface.
<i>Nef_polyhedron_3<Traits>:: Vertex_const_iterator</i>	non-mutable iterator over all vertices.
<i>Nef_polyhedron_3<Traits>:: Halfedge_const_iterator</i>	non-mutable iterator over all halfedges.
<i>Nef_polyhedron_3<Traits>:: Halffacet_const_iterator</i>	non-mutable iterator over all halffacets.
<i>Nef_polyhedron_3<Traits>:: Volume_const_iterator</i>	non-mutable iterator over all volumes.
<i>Nef_polyhedron_3<Traits>:: SVertex_const_iterator</i>	non-mutable iterator over all svertices.
<i>Nef_polyhedron_3<Traits>:: SHalfedge_const_iterator</i>	non-mutable iterator over all shalfedges.
<i>Nef_polyhedron_3<Traits>:: SHalfloop_const_iterator</i>	non-mutable iterator over all shalfloops.
<i>Nef_polyhedron_3<Traits>:: SFace_const_iterator</i>	non-mutable iterator over all sfaces.
<i>Nef_polyhedron_3<Traits>:: SHalfedge_around_svertex_const_circulator</i>	
	non-mutable circulator of shalfedges around a svertex (cw).
<i>Nef_polyhedron_3<Traits>:: SHalfedge_around_sface_const_circulator</i>	
	non-mutable circulator of shalfedges around a sface (ccw).
<i>Nef_polyhedron_3<Traits>:: SHalfedge_around_facet_const_circulator</i>	
	non-mutable circulator of shalfedges around a halffacet (ccw).
<i>Nef_polyhedron_3<Traits>:: SFace_cycle_const_iterator</i>	
	non-mutable iterator over the cycles of a sface.
<i>Nef_polyhedron_3<Traits>:: Halffacet_cycle_const_iterator</i>	
	non-mutable iterator over the cycles of a halffacet.
<i>Nef_polyhedron_3<Traits>:: Shell_entry_const_iterator</i>	
	non-mutable iterator providing an entry to each shell.
<i>Nef_polyhedron_3<Traits>:: Object_handle</i>	a generic handle to an object. The kind of object (<i>vertex</i> , <i>halfedge</i> , <i>halffacet</i> , <i>volume</i> , <i>svertex</i> , <i>shalfedge</i> , <i>shalfloop</i> , <i>sface</i>) can be determined and the object can be assigned to a corresponding constant handle by one of the following functions: <i>bool assign(Vertex_const_handle& h, Object_handle)</i> <i>bool assign(Halfedge_const_handle& h, Object_handle)</i> <i>bool assign(Halffacet_const_handle& h, Object_handle)</i> <i>bool assign(Volume_const_handle& h, Object_handle)</i> <i>bool assign(SVertex_const_handle& h, Object_handle)</i> <i>bool assign(SHalfedge_const_handle& h, Object_handle)</i> <i>bool assign(SHalfloop_const_handle& h, Object_handle)</i> <i>bool assign(SFace_const_handle& h, Object_handle)</i> where each function returns <i>true</i> iff the assignment to <i>h</i> could be accomplished.
<i>Nef_polyhedron_3<Traits>:: Point_3</i>	location of vertices.

Nef_polyhedron_3<Traits>:: Segment_3 segment represented by a halfedge.
Nef_polyhedron_3<Traits>:: Vector_3 direction of a halfedge.
Nef_polyhedron_3<Traits>:: Plane_3 plane of a halffacet lies in.
Nef_polyhedron_3<Traits>:: Aff_transformation_3

affine transformation.

Nef_polyhedron_3<Traits>:: Polylines_tag tag for calling polyline constructor.

enum Boundary { EXCLUDED, INCLUDED};

construction selection.

enum Content { EMPTY, COMPLETE}; construction selection.
enum Intersection_mode { CLOSED_HALFSPACE, OPEN_HALFSPACE, PLANE_ONLY};

intersection selection.

Nef_polyhedron_3<Traits>:: Nef_polyhedron_S2

a sphere map.

Nef_polyhedron_3<Traits>:: Polyhedron a polyhedral surface.

Creation

Nef_polyhedron_3<Traits> N(Content space = EMPTY);

creates a Nef polyhedron and initializes it to the empty set if *plane == EMPTY* and to the whole space if *space == COMPLETE*.

Nef_polyhedron_3<Traits> N(Plane_3 p, Boundary b = INCLUDED);

creates a Nef polyhedron containing the halfspace on the negative side of *p* including *p* if *b==INCLUDED*, excluding *p* if *b==EXCLUDED*.

Nef_polyhedron_3<Traits> N(Polyhedron& P);

creates a Nef polyhedron, which represents the same point set as the polyhedral surface *P* does.

Nef_polyhedron_3<Traits> N(Input_iterator begin, Input_iterator end);

creates a Nef polyhedron consisting of a single polygon spanned by the list of points in the iterator range *[begin,end)*. If the points do not on a common supporting plane, the constructor tries to triangulate the polygon into multiple facets.If the construction does not succeed, the empty set is created.

template <class Forward_iterator>

Nef_polyhedron_3<Traits> N(Forward_iterator it, Forward_iterator end, Polylines_tag);

The iterator range [it, end) defines a set point ranges, each of which defines a polyline.

Access Member Functions

<i>bool</i>	<i>N.is_simple()</i>	returns true, if <i>N</i> is a 2-manifold.
<i>bool</i>	<i>N.is_valid()</i>	checks the integrity of <i>N</i> .
<i>Size_type</i>	<i>N.number_of_vertices()</i>	returns the number of vertices.
<i>Size_type</i>	<i>N.number_of_halfedges()</i>	return the number of halfedges.
<i>Size_type</i>	<i>N.number_of_edges()</i>	returns the number of halfedge pairs.
<i>Size_type</i>	<i>N.number_of_halffacets()</i>	returns the number of halffacets.
<i>Size_type</i>	<i>N.number_of_facets()</i>	returns the number of halffacet pairs.
<i>Size_type</i>	<i>N.number_of_volumes()</i>	returns the number of volumes.
<i>Vertex_const_iterator</i>	<i>N.vertices_begin()</i>	iterator over all vertices.
<i>Vertex_const_iterator</i>	<i>N.vertices_end()</i>	past-the-end iterator.
<i>Halfedge_const_iterator</i>	<i>N.halfedges_begin()</i>	iterator over all halfedges.
<i>Halfedge_const_iterator</i>	<i>N.halfedges_end()</i>	past-the-end iterator.
<i>Halffacet_const_iterator</i>	<i>N.halffacets_begin()</i>	iterator over all halffacets.
<i>Halffacet_const_iterator</i>	<i>N.halffacets_end()</i>	past-the-end iterator.
<i>Volume_const_iterator</i>	<i>N.volumes_begin()</i>	iterator over all volumes.
<i>Volume_const_iterator</i>	<i>N.volumes_end()</i>	past-the-end iterator.

The following macros are provided: *CGAL_forall_vertices(v,N)*, *CGAL_forall_halfedges(e,N)*, *CGAL_forall_edges(e,N)*, *CGAL_forall_halffacets(f,N)*, *CGAL_forall_facets(f,N)*, *CGAL_forall_volumes(c,N)* where *N* is a *Nef_polyhedron_3*.

<i>Object_handle</i>	<i>N.locate(Point_3 p)</i>	returns a generic handle to the object (vertex, edge, facet or volume) which contains the point p in its relative interior.
<i>Nef_polyhedron_S2</i>	<i>N.get_sphere_map(Vertex_const_iterator v)</i>	returns the neighborhood of a vertex modeled by a <i>Nef_polyhedron_S2</i> .

Point Set Predicates

<i>bool</i>	<i>N.is_empty()</i>	returns true, if <i>N</i> is the empty point set.
<i>bool</i>	<i>N.is_space()</i>	returns true, if <i>N</i> is the complete 3D space.
<i>bool</i>	<i>N == N1</i>	returns true, if <i>N</i> and <i>N1</i> comprise the same point sets.

<i>bool</i>	$N \neq N1$	returns true, if N and $N1$ comprise different point sets.
<i>bool</i>	$N < N1$	returns true, if N is a proper subset of $N1$.
<i>bool</i>	$N > N1$	returns true, if N is a proper superset of $N1$.
<i>bool</i>	$N \leq N1$	returns true, if N is a subset of $N1$.
<i>bool</i>	$N \geq N1$	returns true, if N is a superset of $N1$.

Unary Set Operations

<i>Nef_polyhedron_3<Traits></i>	<i>N.complement()</i>	returns the complement of N .
<i>Nef_polyhedron_3<Traits></i>	<i>N.interior()</i>	returns the interior of N .
<i>Nef_polyhedron_3<Traits></i>	<i>N.boundary()</i>	returns the boundary of N .
<i>Nef_polyhedron_3<Traits></i>	<i>N.closure()</i>	returns the closure of N .
<i>Nef_polyhedron_3<Traits></i>	<i>N.regularization()</i>	returns the regularization, i.e. the closure of the interior, of N .
<i>Nef_polyhedron_3<Traits></i>	$!N$	returns the complement of N .

Binary Set Operations

<i>Nef_polyhedron_3<Traits></i>	<i>N.intersection(N1)</i>	return the intersection of N and $N1$.
<i>Nef_polyhedron_3<Traits></i>	<i>N.join(N1)</i>	return the union of N and $N1$. (Note that "union" is a C++ keyword and cannot be used for this operation.)
<i>Nef_polyhedron_3<Traits></i>	<i>N.difference(N1)</i>	return the difference between N and $N1$.
<i>Nef_polyhedron_3<Traits></i>	<i>N.symmetric_difference(N1)</i>	return the symmetric difference of N and $N1$.
<i>Nef_polyhedron_3<Traits></i>	<i>N.intersection(Plane_3 p, Intersection_mode im)</i>	returns intersection of N with plane ($im=PLANE_ONLY$), open halfspace ($im=OPEN_HALFSPACE$), or closed halfspace ($im=CLOSED_HALFSPACE$). In the latter two cases, the halfspaces are on the negative side of the plane p . The function is written for the use with standard kernels, where halfspaces are not part of the domain. The function does not work in combination with an extended kernels or with an unbounded polyhedron.
<i>Nef_polyhedron_3<Traits></i>	$N * N1$	return the intersection of N and $N1$.
<i>Nef_polyhedron_3<Traits></i>	$N + N1$	return the union of N and $N1$.
<i>Nef_polyhedron_3<Traits></i>	$N - N1$	return the difference between N and $N1$.
<i>Nef_polyhedron_3<Traits></i>	$N \wedge N1$	return the symmetric difference of N and $N1$.
<i>void</i>	$N * = N1$	intersects N and $N1$.
<i>void</i>	$N + = N1$	unites N with $N1$.
<i>void</i>	$N - = N1$	subtracts $N1$ from N .
<i>void</i>	$N \wedge = N1$	performs a symmetric intersection of N and $N1$.

Operations

void *N.clear(Content space = EMPTY)*

make *N* the empty set if *space == EMPTY* and the complete 3D space if *space == COMPLETE*.

void *N.transform(Aff_transformation_3 aff)*

applies an affine transformation to *N* .

void *N.convert_to_polyhedron(Polyhedron& P)*

converts *N* into a Polyhedron.

Precondition: *N* is simple.

void *N.visit_shell_objects(SFace_const_handle f, Visitor& V)*

calls the visit function of *V* for every item which belongs to the same shell as *sf*.

CGAL::Nef_polyhedron_3<Traits>::Vertex

Definition

A vertex is a point in the 3-dimensional space. Its incidence structure can be accessed creating a sphere map of the vertex. This is done by the member function *get_sphere_map* of the class *Nef_polyhedron_3*.

```
#include <CGAL/Nef_polyhedron_3.h>
```

Types

The following types are the same as in *Nef_polyhedron_3*<Traits>.

Vertex::Mark type of mark.

Vertex::Point_3 point type stored in Vertex.

Creation

There is no need for a user to create a *Vertex* explicitly. The class *Nef_polyhedron_3<Traits>* manages the needed vertices internally.

Operations

<i>Mark</i>	$v.mark()$	the mark of v .
-------------	------------	-------------------

<i>Point_3</i>	<i>v.point()</i>	the point of <i>v</i> .
----------------	------------------	-------------------------

CGAL::Nef_polyhedron_3<Traits> page 1877

CGAL::Nef_polyhedron_S2<Traits> page 1569

CGAL::Nef_polyhedron_3<Traits>::Halfedge

Definition

A Halfedge has a double meaning. In the global incidence structure of a *Nef_polyhedron_3* it is an oriented edge going from one vertex to another. A halfedge also coincides with an svertex of the sphere map of its source vertex. Because of this, we offer the types *Halfedge* and *SVertex* which are the same. Furthermore, the redundant functions *center_vertex()* and *source()* are provided. The reason is, that we get the same vertex either if we want to have the source vertex of a halfedge, or if we want to have the vertex in the center of the sphere map a svertex lies on. Figures 27.9 and 27.9 illustrate the incidence of a svertex on a sphere map and of a halfedge in the global structure.

As part of the global incidence structure, the member functions *source* and *target* return the source and target vertex of an edge. The member function *twin()* returns the opposite halfedge.

Looking at the incidence structure on a sphere map, the member function *out_sedge* returns the first outgoing shalfedge, and *incident_sface* returns the incident sface.

```
#include <CGAL/Nef_polyhedron_3.h>
```

Types

The following types are the same as in *Nef_polyhedron_3<Traits>*.

<i>Halfedge::Mark</i>	type of mark.
<i>Halfedge::Sphere_point</i>	sphere point type stored in Halfedge.
<i>Halfedge::Vertex_const_handle</i>	const handle to vertex.
<i>Halfedge::Halfedge_const_handle</i>	const handle to halfedge.
<i>Halfedge::SHalfedge_const_handle</i>	const handle to SHalfedge.
<i>Halfedge::SFace_const_handle</i>	const handle to SFace.

Creation

There is no need for a user to create a *Halfedge* explicitly. The class *Nef_polyhedron_3<Traits>* manages the needed halfedges internally.

Operations

<i>Mark</i>	<i>e.mark()</i>	the mark of <i>e</i> .
<i>Sphere_point</i>	<i>e.point()</i>	the sphere point of <i>e</i> .
<i>bool</i>	<i>e.is_isolated()</i>	returns —true— if <i>e</i> has no adjacent sedges.
<i>Vertex_const_handle</i>	<i>e.center_vertex()</i>	the center vertex of the sphere map <i>e</i> belongs to.

<i>Vertex_const_handle</i>	<i>e.source()</i>	the source vertex of <i>e</i> .
<i>Vertex_const_handle</i>	<i>e.target()</i>	the target vertex <i>e</i> .
<i>Halfedge_const_handle</i>	<i>e.twin()</i>	the twin of <i>e</i> .
<i>SHalfedge_const_handle</i>		
	<i>e.out_sedge()</i>	the first out sedege of <i>e</i> .
<i>SFace_const_handle</i>	<i>e.incident_sface()</i>	the incident sface of <i>e</i> .

CGAL::Nef_polyhedron_3<Traits>::Halffacet

Definition

A halffacet is an oriented, rectilinear bounded part of a plane. The following figure depicts the incidences to halfedges, vertices and the notion of facet cycles.

The member function *twin* returns the opposite halffacet, *incident_volume* returns the incident volume. A Halffacet cycle either consists of consecutive halfedges along the border (or a hole) of the halffacet, or of a single halfloop on the sphere map of a vertex isolated on the halffacet. The iterator range (*halffacet_cycles_begin()/halffacet_cycles_end()*) provides an entry element for each halffacet cycle of a halffacet.

```
#include <CGAL/Nef_polyhedron_3.h>
```

Types

The following types are the same as in *Nef_polyhedron_3<Traits>*.

<i>Halffacet:: Mark</i>	type of mark.
<i>Halffacet:: Plane_3</i>	plane type stored in Halffacet.
<i>Halffacet:: Object_list</i>	list of Object handles.
<i>Halffacet:: Halffacet_const_handle</i>	const handle to Halffacet.
<i>Halffacet:: Volume_const_handle</i>	const handle to volume.
<i>Halffacet:: Halffacet_cycle_const_iterator</i>	const iterator over the entries to all halffacet cycles of a halffacet.

Creation

There is no need for a user to create a *Halffacet* explicitly. The class *Nef_polyhedron_3<Traits>* manages the needed halffacets internally.

Operations

<i>Mark</i>	<i>f.mark()</i>	the mark of <i>f</i> .
<i>Plane_3</i>	<i>f.plane()</i>	the supporting plane of <i>f</i> .
<i>Halffacet_const_handle</i>	<i>f.twin()</i>	the twin of <i>f</i> .
<i>Volume_const_handle</i>	<i>f.incident_volume()</i>	the incident volume of <i>f</i> .
<i>Halffacet_cycle_const_iterator</i>	<i>f.facet_cycle_begin()</i>	iterator over the entries to all halffacet cycles of <i>f</i> .
<i>Halffacet_cycle_const_iterator</i>	<i>f.facet_cycle_end()</i>	past-the-end iterator.

CGAL::Nef_polyhedron_3<Traits>::Volume

Definition

A volume is a full-dimensional connected point set in \mathbb{R}^3 . It is bounded by several shells, i.e. a connected part of the boundary incident to a single volume. An entry element to each shell is provided by the iterator range (*shells_begin()/shells_end()*). A *Shell_entry_iterator* is assignable to *SFace_handle*.

```
#include <CGAL/Nef_polyhedron_3.h>
```

Types

The following types are the same as in *Nef_polyhedron_3<Traits>*.

<i>Volume:: Mark</i>	type of mark.
<i>Volume:: Object_list</i>	list of Object handles.
<i>Volume:: Volume_const_handle</i>	const handle to Volume.
<i>Volume:: Shell_entry_const_iterator</i>	const iterator over the entries to all shells adjacent to a volume.

Creation

There is no need for a user to create a *Volume* explicitly. The class *Nef_polyhedron_3<Traits>* manages the needed volumes internally.

Operations

<i>Mark</i>	<i>c.mark()</i>	the mark of <i>c</i> .
<i>Shell_entry_const_iterator</i>	<i>c.shells_begin()</i>	const iterator over the entries to all shells adjacent to <i>c</i> .
<i>Shell_entry_const_iterator</i>	<i>c.shells_end()</i>	past-the-end iterator.

CGAL::Nef_polyhedron_3<Traits>::SHalfedge

Definition

A shalfedge is a great arc on a sphere map. Figure 27.9 depicts the relationship between a shalfedge and its incident shalfedges, svertices, and sfaces on a sphere map. A shalfedge is an oriented sedge between two svertices. It is always paired with a shalfedge pointing in the opposite direction. The *twin()* member function returns this shalfedge of opposite orientation.

The *snext()* member function points to the successor shalfedge around this sface while the *sprev()* member function points to the preceding shalfedge. An successive assignments of the form *se = se->snext()* cycles counterclockwise around the sface (or hole).

Similarly, the successive assignments of the form *se = se->snext()->twin()* cycle clockwise around the svertex and traverse all halfedges incident to this svertex. The assignment *se = se->cyclic_adj_succ()* can be used as a shortcut.

The role of shalfedges in a facet is illustrated in Figure 27.9. The *facet()* member function returns the facet in which the shalfedge is part of one of the facet cycles. The successive assignment of the form *se = se->next()* cycles counterclockwise around the facet (or a hole of the facet).

A const circulators is provided for each of the three circular orders. The circulators are bidirectional and assignable to *SHalfedge_const_handle*.

```
#include <CGAL/Nef_polyhedron_3.h>
```

Types

The following types are the same as in *Nef_polyhedron_3<Traits>*.

SHalfedge::Mark type of mark.

SHalfedge::Sphere_circle sphere circle type stored in SHalfedge.

SHalfedge::Halffacet_const_handle const handle to Halffacet.

SHalfedge::SVertex_const_handle const handle to SVertex.

SHalfedge::SHalfedge_const_handle const handle to SHalfedge.

SHalfedge::SFace_const_handle const handle to SFace.

Creation

There is no need for a user to create a *SHalfedge* explicitly. The class *Nef_polyhedron_3<Traits>* manages the needed shalfedges internally.

Operations

<i>Mark</i>	<i>se.mark()</i>	the mark of <i>se</i> .
<i>Sphere_circle</i>	<i>se.circle()</i>	the sphere circle of <i>se</i> .
<i>SHalfedge_const_handle</i>	<i>se.twin()</i>	the twin of <i>se</i> .
<i>SVertex_const_handle</i>	<i>se.source()</i>	the source svertex of <i>se</i> .
<i>SVertex_const_handle</i>	<i>se.target()</i>	equals <i>twin()->source()</i> .
<i>SHalfedge_const_handle</i>	<i>se.prev()</i>	the SHalfedge previous to <i>se</i> in a facet cycle.
<i>SHalfedge_const_handle</i>	<i>se.next()</i>	the next SHalfedge of <i>se</i> in a facet cycle.
<i>SHalfedge_const_handle</i>	<i>se.sprev()</i>	the SHalfedge previous to <i>se</i> in a sface cycle.
<i>SHalfedge_const_handle</i>	<i>se.snext()</i>	the next SHalfedge of <i>se</i> in a sface cycle.
<i>SHalfedge_const_handle</i>	<i>se.cyclic_adj_pred()</i>	the edge before <i>se</i> in the cyclic ordered adjacency list of <i>source()</i> .
<i>SHalfedge_const_handle</i>	<i>se.cyclic_adj_succ()</i>	the edge after <i>se</i> in the cyclic ordered adjacency list of <i>source()</i> .
<i>Halffacet_const_handle</i>	<i>se.facet()</i>	the facet that corresponds to <i>se</i> in the 3D incidence structure.
<i>SFace_const_handle</i>	<i>se.incident_sface()</i>	the incident sface of <i>se</i> .
<i>bool</i>	<i>se.in_outer_sface_cycle()</i>	determines whether <i>se</i> is in an outer sface cycle.
<i>bool</i>	<i>se.in_inner_sface_cycle()</i>	determines whether <i>se</i> is in an inner sface cycle.
<i>bool</i>	<i>se.in_outer_facet_cycle()</i>	determines whether <i>se</i> is in an outer facet cycle.

```
se.in_inner_facet_cycle()
```

determines whether se is in an inner facet cycle.

CGAL::Nef_polyhedron_3<Traits>::SHalfloop

Definition

A shalfloop is a great circle on a sphere map. Figure 27.9 depicts the relationship between a shalfloop and its incident shalfloops, and sfaces on a sphere map. A shalfloop is an oriented sloop. It is always paired with a shalfloop whose supporting *Sphere_circle* is pointing in the opposite direction. The *twin()* member function returns this shalfloop of opposite orientation.

A sphere map having a shalfloop models the neighborhood of a vertex which is isolated on a facet. That facet is returned by the member function *facet*.

```
#include <CGAL/Nef_polyhedron_3.h>
```

Types

The following types are the same as in *Nef_polyhedron_3<Traits>*.

<i>SHalfloop::Mark</i>	type of mark.
<i>SHalfloop::Sphere_circle</i>	sphere circle type stored in SHalfloop.
<i>SHalfloop::Halfacet_const_handle</i>	const handle to Halfacet.
<i>SHalfloop::SHalfloop_const_handle</i>	const handle to SHalfloop.
<i>SHalfloop::SFace_const_handle</i>	const handle to SFace.

Creation

There is no need for a user to create a *SHalfloop* explicitly. The class *Nef_polyhedron_3<Traits>* manages the needed shalfloops internally.

Operations

<i>Mark</i>	<i>se.mark()</i>	the mark of <i>se</i> .
<i>Sphere_circle</i>	<i>se.circle()</i>	the sphere circle of <i>se</i> .

<i>SHalfloop_const_handle</i>	<i>se.twin()</i>	the twin of <i>se</i> .
<i>Halffacet_const_handle</i>	<i>se.facet()</i>	the facet that corresponds to <i>se</i> in the 3D incidence structure.
<i>SFace_const_handle</i>	<i>se.incident_sface()</i>	the incident sface of <i>se</i> .

CGAL::Nef_polyhedron_3<Traits>::SFace

Definition

Figures 27.9 and 27.9 illustrate the incidences of an sface. An sface is described by its boundaries. An entry item to each boundary cycle can be accessed using the iterator range (*sface_cycles_begin()*/*sface_cycles_end()*). Additionally, *Nef_polyhedron_S2* provides the macro *CGAL_forall_sface_cycles_of*. The iterators are of type *SFace_cycle_const_iterator* and represent either a shalfedge, a shalfloop, or a svertex.

```
#include <CGAL/Nef_polyhedron_3.h>
```

Types

The following types are the same as in *Nef_polyhedron_3<Traits>*.

<i>SFace:: Mark</i>	type of mark.
<i>SFace:: Object_list</i>	list of Object handles.
<i>SFace:: Vertex_const_handle</i>	const handle to Vertex.
<i>SFace:: Volume_const_handle</i>	const handle to Volume.
<i>SFace:: SFace_const_handle</i>	const handle to SFace.
<i>SFace:: SFace_cycle_const_iterator</i>	const iterator over the entries to all sface cycles of a sface.

Creation

There is no need for a user to create a *SFace* explicitly. The class *Nef_polyhedron_3<Traits>* manages the needed sfaces internally.

Operations

<i>Mark</i>	<i>sf.mark()</i>	the mark of <i>sf</i> .
<i>Vertex_const_handle</i>	<i>sf.center_vertex()</i>	the center vertex of the sphere map <i>sf</i> belongs to.
<i>Volume_const_handle</i>	<i>sf.volume()</i>	the volume that corresponds to <i>sf</i> in the 3D incidence structure.
<i>SFace_cycle_const_iterator</i>	<i>sf.sface_cycle_begin()</i>	iterator over the entries to all sface cycles of <i>sf</i> .
<i>SFace_cycle_const_iterator</i>	<i>sf.sface_cycle_end()</i>	past-the-end iterator.

CGAL::Nef_polyhedron_3<Traits>::Halfacet_cycle_iterator

Definition

The type *Halfacet_cycle_iterator* iterates over a list of *Object_handles*. Each item of that list can either be assigned to *SHalfedge_handle* or *SHalfloop_handle*. To find out which of these assignment works out, the member functions *is_shalfedge()* and *is_shalfloop()* are provided.

```
#include <CGAL/Nef_polyhedron_3.h>
```

Types

<i>Halfacet_cycle_iterator::SHalfedge_handle</i>	const handle to <i>SHalfedge</i> .
<i>Halfacet_cycle_iterator::SHalfloop_handle</i>	const handle to <i>SHalfloop</i> .

Creation

<i>Halfacet_cycle_iterator hfc;</i>	default constructor.
-------------------------------------	----------------------

Operations

<i>bool</i>	<i>hfc.is_shalfedge()</i>	returns true if <i>hfc</i> represents a <i>SHalfedge_handle</i> .
<i>bool</i>	<i>hfc.is_shalfloop()</i>	returns true if <i>hfc</i> represents a <i>SHalfloop_handle</i> .
<i>SHalfedge_handle</i>	<i>SHalfedge_handle(hfc)</i>	casts <i>hfc</i> to <i>SHalfedge_handle</i> .
<i>SHalfloop_handle</i>	<i>SHalfloop_handle(hfc)</i>	casts <i>hfc</i> to <i>SHalfloop_handle</i> .

CGAL::OFF_to_nef_3

Definition

This constructor creates a 3D Nef polyhedron from OFF file. OFF file is read from input stream *in*. The purpose of *OFF_to_nef_3* is to create a Nef polyhedron from an OFF file that cannot be handled by the *Nef_polyhedron_3* constructors. It handles double coordinates while using a homogenous kernel, non-coplanar facets, surfaces with boundaries, self-intersecting surfaces, and single facets. Every closed volume gets marked. The function returns the number of facets it could not handle.

```
template<class Nef_polyhedron_3>
std::size_t      OFF_to_nef_3( std::istream& in, Nef_polyhedron_3& N)
```

CGAL::Nef_polyhedron_3<Traits> page [1877](#)

CGAL::Nef_nary_union_3<Nef_polyhedron_3>

Definition

This class helps to perform the union of a set of 3D Nef polyhedra efficiently. It successively applies the binary union operation of *Nef_polyhedron_3*, but schedules these union operations in an opportune way. The class is most efficient, if the polyhedra are added in sorted order. Any order that reflects proximity in the three-dimensional space is helpful. To allow saving memory space, the sorting is left to the user. This way the user can generate the polyhedra in a sorted way and add them one by one to *Nef_nary_union_3*.

```
#include <CGAL/Nef_nary_union_3.h>
```

Parameters

```
template < class Nef_polyhedron_3,
class Nef_nary_union_3;
```

As a template parameter an instantiation of the template class Nef polyhedra is needed.

Creation

```
Nef_nary_union_3<Nef_polyhedron_3> U;      initialization only.
```

Member Functions

<i>Nef_polyhedron_3</i>	<i>U.get_union()</i>
	returns the union of the polyhedra previously added to the class.

void	<i>U.add_polyhedron(Nef_polyhedron_3 N)</i>
	adds a polyhedron.

CGAL::Nef_polyhedron_3<Traits> page [1877](#)

CGAL::operator<<

Definition

This operator writes The Nef polyhedron N to the output stream *out* using a propriatary file format. It includes the complete incidence structure, the geometric data, and the marks of each item.

Using CGAL stream modifiers the following output formats can be chosen: ASCII(*set_ascii_mode*), binary(*set_binary_mode*) or pretty(*set_pretty_mode*). The mandatory format is the ASCII format. It is recommended to use this format for file input and output.

As the output depends on the output operators of the geometric primitives provided by the traits class, it might not be possible that the input operator and output operators of different traits classes are not compatible. We recommend to use the CGAL kernels *Homogeneous*, *Simple_homogeneous*, or *Extended_homogeneous* parametrized with any exact number type that models \mathbb{Z} (e.g. *Gmpz* or *leda_integer*).

A bounded *Nef_polyhedron_3*<*Extended_homogeneous*> is automatically written as though *Nef_polyhedron_3*<*CGAL::Homogeneous*> or *Nef_polyhedron_3*<*CGAL::Simple_homogeneous*> is used. As a result, the input operator of each of these types can read the output.

```
#include <CGAL/IO/Nef_polyhedron_iostream_3.h>
```

```
template <class Traits>
ostream& ostream& out << CGAL::Nef_polyhedron_3<Traits> N
```

CGAL::operator>>

Definition

This operator reads a Nef polyhedron, which is given in the proprietary file format written by the input operator *in* and assigns it to *N*. It includes the complete incidence structure, the geometric data, and the marks of each item.

It is recommended to use the CGAL kernels *Homogeneous*, *Simple_homogeneous*, or *Extended_homogeneous* parametrized with any exact number type that models \mathbb{Z} (e.g. *Gmpz* or *leda_integer*). The input and output iterators of Nef polyhedra parametrized with either of these kernels are compatible as long as the Nef polyhedron is bounded. An unbounded Nef polyhedron can only be read by a Nef polyhedron parametrized with an extended kernel. It is also recommended to use the CGAL stream modifier *set_ascii_mode*.

```
#include <CGAL/IO/Nef_polyhedron_iostream_3.h>
```

```
template <class Traits>
istream& operator>> (istream& in) { CGAL::Nef_polyhedron_3<Traits>& N
```

CGAL::Qt_widget_Nef_3<Nef_polyhedron_3>

Definition

The class *Qt_widget_Nef_3* uses the OpenGL interface of Qt to display a *Nef_polyhedron_3*. Its purpose is to provide an easy to use viewer for *Nef_polyhedron_3*. There are no means provided to enhance the functionality of the viewer.

In addition to the functions inherited from the Qt class *OpenGLWidget* via, *Qt_widget_Nef_3* only has a single public constructor. For the usage of *Qt_widget_Nef_3* see the example below.

```
#include <CGAL/IO/Qt_widget_Nef_3.h>
```

Parameters

The template parameter expects an instantiation of *Nef_polyhedron_3<Traits>*.

Creation

```
Qt_widget_Nef_3<Nef_polyhedron_3> W( Nef_polyhedron_3 N);
```

Creates a widget *W* for displaying the 3D Nef polyhedron *N*.

See Also

CGAL::Nef_polyhedron_3<Traits> page [1877](#)

Example

This example reads a 3D Nef polyhedron from standard input and displays it in a Qt widget.

```
#include <CGAL/basic.h>
#include <CGAL/Gmpz.h>
#include <CGAL/Homogeneous.h>
#include <CGAL/Nef_polyhedron_3.h>
#include <CGAL/IO/Nef_polyhedron_istream_3.h>
#include <CGAL/IO/Qt_widget_Nef_3.h>
#include <qapplication.h>

typedef CGAL::Homogeneous<CGAL::Gmpz> Kernel;
typedef CGAL::Nef_polyhedron_3<Kernel> Nef_polyhedron_3;

int main(int argc, char* argv[]) {
    Nef_polyhedron_3 N;
    std::cin >> N;

    QApplication a(argc, argv);
```

```
CGAL::Qt_widget_Nef_3<Nef_polyhedron_3>* w =  
    new CGAL::Qt_widget_Nef_3<Nef_polyhedron_3>(N);  
a.setMainWidget(w);  
w->show();  
return a.exec();  
}
```

Chapter 28

Convex Decomposition of Polyhedra

Peter Hachenberger

28.1 Introduction

For many applications on non-convex polyhedra, there are efficient solutions that first decompose the polyhedron into convex pieces. As an example, the Minkowski sum of two polyhedra can be computed by decomposing both polyhedra into convex pieces, compute pair-wise Minkowski sums of the convex pieces, and unite the pair-wise sums.

While it is desirable to have a decomposition into a minimum number of pieces, this problem is known to be NP-hard [Cha84]. Our implementation decomposes a Nef polyhedron N into $O(r^2)$ convex pieces, where r is the number of edges that have two adjacent facets that span an angle of more than 180 degrees with respect to the interior of the polyhedron. Those edges are also called reflex edges. The bound of $O(r^2)$ convex pieces is worst-case optimal [Cha84].

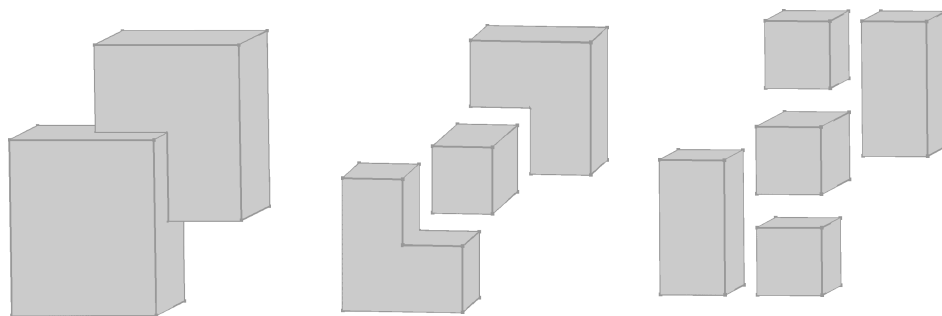

Figure 28.1: Vertical decomposition based on the insertion of vertical facets (viewed from the top). Left: Non-convex polyhedron. Middle: Non-vertical reflex edges have been resolved. Right: Vertical reflex edges have been resolved. The sub-volumes are convex.

Our decomposition runs in two steps. In the first step, each non-vertical reflex edge e is resolved by insertion of vertical facets through e . In the second step, we do the same with the vertical reflex edges. Figure 28.1 illustrates the two steps.

At the moment our implementation is restricted to the decomposition of bounded polyhedra. An extension to unbounded polyhedra is planned.

28.2 Interface and Usage

An instance of *Nef_polyhedron_3* represents a subdivision of the three-dimensional space into vertices, edges, facets, and volumes. Some of these items form the polyhedron (selected), while others represent the outer volume or holes within the polyhedron (unselected). As an example, the unit cube is the point set $[0, 1]^3$. The smallest subdivision that represents the unit cube has 8 vertices, 12 edges, 6 facets, and 2 volumes. The volumes enclosed by the vertices, edges, and facets is the interior of the cube and therefore selected. The volume outside the cube does not belong to it and is therefore unselected. The vertices, edges, and facets—also denoted as boundary items—are needed to separate the two volumes, but are also useful for representing topological properties. In case of the (closed) unit cube the boundary items are part of the polyhedron and therefore selected, but in case of the open unit cube $[0, 1)^3$ they are unselected. Each item has its own selection mark, which allows the correct representation of Nef polyhedra, which are closed under Boolean and topological operations. Details can be found in the chapter on 3D Boolean operations on Nef polyhedra [27](#).

Usually, an instance of *Nef_polyhedron_3* does not contain any redundant items. However, the function *convex_decomposition_3* subdivides selected volumes of a given *Nef_polyhedron_3* by selected facets. These additional facets are therefore redundant, i.e., their insertion alters the representation of the polyhedron, but not the polyhedron itself.

When *convex_decomposition_3* resolved all reflex edges, the selected sub-volumes have become convex. Each of them is represented by a separate volume item and can therefore be traversed separately [27.7.2](#). Another possibility of accessing the convex pieces is to convert them into separate Nef polyhedra, as illustrated by the example code given below.

Note that due to the restriction to bounded polyhedra, the use of extended kernels is unnecessary and expensive. We therefore do not support the use of extended kernels in the convex decomposition (see Chapter [27](#)).

```
#include <CGAL/Exact_predicates_exact_constructions_kernel.h>
#include <CGAL/Polyhedron_3.h>
#include <CGAL/Nef_polyhedron_3.h>
#include <CGAL/IO/Nef_polyhedron_iostream_3.h>
#include <CGAL/Nef_3/SNC_indexed_items.h>
#include <CGAL/convex_decomposition_3.h>
#include <list>

typedef CGAL::Exact_predicates_exact_constructions_kernel Kernel;
typedef CGAL::Polyhedron_3<Kernel> Polyhedron_3;
typedef CGAL::Nef_polyhedron_3<Kernel, CGAL::SNC_indexed_items>
    Nef_polyhedron_3;
typedef Nef_polyhedron_3::Volume_const_iterator Volume_const_iterator;

int main() {

    Nef_polyhedron_3 N;
    std::cin >> N;

    CGAL::convex_decomposition_3(N);
    std::list<Polyhedron_3> convex_parts;

    // the first volume is the outer volume, which is
```

```

// ignored in the decomposition
Volume_const_iterator ci = ++N.volumes_begin();
for( ; ci != N.volumes_end(); ++ci) {
    if(ci->mark()) {
        Polyhedron_3 P;
        N.convert_inner_shell_to_polyhedron(ci->shells_begin(), P);
        convex_parts.push_back(P);
    }
}
std::cout << "decomposition into " << convex_parts.size() << " convex
parts " << std::endl;
}

```

convex_decomposition_3 page [1908](#)

CGAL::convex_decomposition_3

Definition

The function *convex_decomposition_3* inserts additional facets into the given *Nef_polyhedron_3* N , such that each bounded marked volume (the outer volume is unbounded) is subdivided into convex pieces. The modified polyhedron represents a decomposition into $O(r^2)$ convex pieces, where r is the number of edges that have two adjacent facets that span an angle of more than 180 degrees with respect to the interior of the polyhedron.

The worst-case running time of our implementation is $O(n^2 r^4 \sqrt[3]{nr^2} \log(nr))$, where n is the complexity of the polyhedron (the complexity of a *Nef_polyhedron_3* is the sum of its *Vertices*, *Halfedges* and *SHalfedges*) and r is the number of reflex edges.

void *convex_decomposition_3*(*Nef_polyhedron_3* & N)

Precondition:

The polyhedron N is bounded. Otherwise, the outer volume is ignored.

Postcondition:

If the polyhedron N is non-convex, it is modified to represent the convex decomposition. If N is convex, it is not modified.

Chapter 29

3D Minkowski Sum of Polyhedra

Peter Hachenberger

29.1 Introduction

Figure 29.1: The Minkowski sum of a spoon and a star.

The Minkowski sum of two point sets P and Q in \mathbb{R}^d , denoted by $P \oplus Q$, is defined as the set $\{p + q : p \in P, q \in Q\}$. Minkowski sums are used in a wide range of applications such as robot motion planning [Lat91] and computer-aided design [EK99]. Figure 29.2 shows an example how Minkowski sums can be used to plan the motion of a translational robot. We want to know which are legal positions of the robot, and where can the robot go to from a specified starting position. If we model both the robot and the obstacles as a polyhedron and compute the Minkowski sum of the inverted robot (robot reflected at the origin) and the obstacles, then this Minkowski sum represents all illegal positions of the robot, i.e., all positions where it intersects the obstacle. Of course, the complement of that polyhedron describes all legal positions of the robot, i.e., all positions where it does not intersect an obstacle.

The Minkowski sum can be illustrated as follows. Pick an arbitrary reference point r of P (black dot in the lower left corner of the robot in Figure 29.2). Then place the inverted set $-P$ on Q , such that $-r$ is on the boundary of Q . Finally, move $-P$ along the complete boundary of Q . The union of Q and the points swept by $-P$ is the Minkowski sum of P and Q .

Implementing the Minkowski sum, the reference point does not need to be chosen. It is implicitly given as the origin of the coordinate system. Choosing a different reference point is equivalent to translating the coordinate system. Such a translation does not change the shape of the Minkowski sum; it only translates the Minkowski sum by the same vector.

This package provides a function `minkowski_sum_3` that computes the Minkowski sum of two Nef polyhedra.

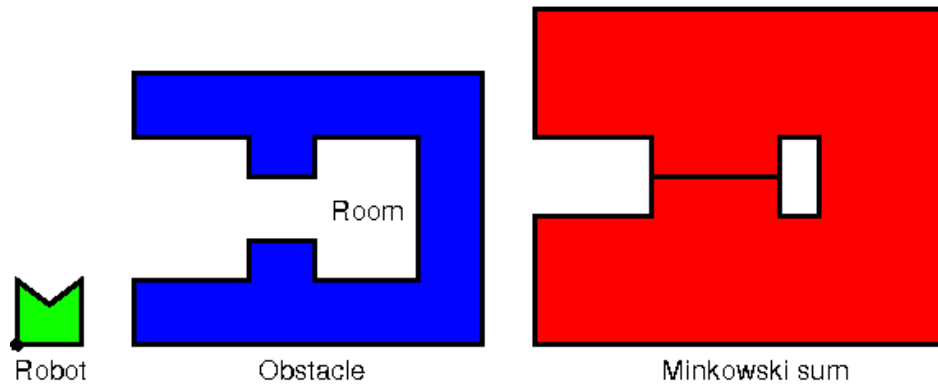

Figure 29.2: Can the robot enter the room? The Minkowski sum of the inverted robot and the obstacle describes the illegal positions of the robot with respect to the obstacle. Since the boundary of the Minkowski sum describes legal positions, there is a path for the robot between the outer area and the room.

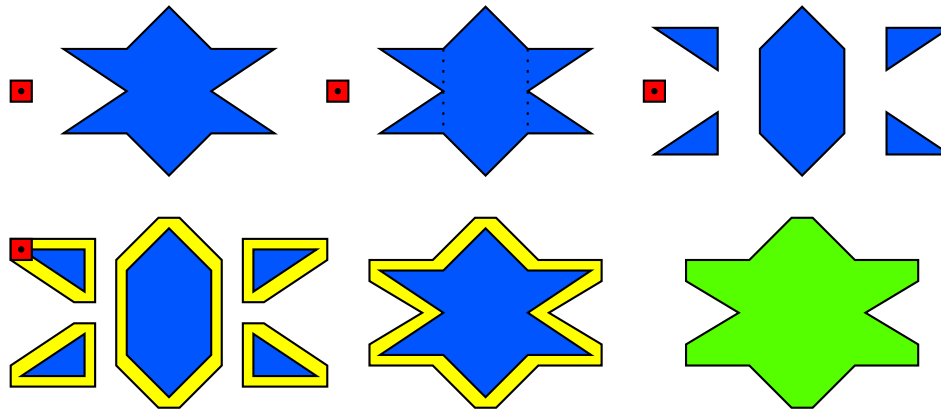

Figure 29.3: The decomposition method decomposes both input polyhedra into convex parts, computes all pairwise Minkowski sums of the convex parts, and merges the pairwise sums.

We do not support arbitrary Nef polyhedra, yet. The restrictions are discussed in detail in Section 29.3.

29.2 Decomposition Method

The decomposition method for computing the Minkowski sum of non-convex polyhedra makes use of the fact that Minkowski sums of convex polyhedra are rather easy to compute. It decomposes both polyhedra into convex pieces, computes all pairwise Minkowski sums of the convex pieces, and merges the pairwise sums [dBvKOS97].

Minkowski sum are inherently complex to compute. Using the decomposition method, each polyhedron might be divided into a quadratic number of pieces, which is worst-case optimal. Then up to n^2m^2 pairwise sums have to be computed and merged, where n and m are the complexities of the two input polyhedra (the complexity of a *Nef_polyhedron_3* is the sum of its *Vertices*, *Halfedges* and *SHalfedges*). In total the operation runs in $O(n^3m^3)$ time.

Since the computation of the Minkowski sum takes quite some time, we give the running times of some

Minkowski sum computations. They were computed with CGAL 3.3 on a machine with a 2.4 GHz AMD Opteron processor and 4 GB RAM. The code was compiled with g++ 3.2 and compiler options -O2. The *Nef_polyhedron_3* class was instantiated with the geometric kernel *Homogeneous<leda_integer>*. The Minkowski sum of the spoon and the star is illustrated in Figure 29.1.

model 1			model 2			running time
name	facets	conv. pcs.	name	facets	conv. pcs.	
mushroom	448	255	cube	6	1	204s
mushroom	448	255	ball1	128	1	553s
spoon	336	186	star	24	5	882s
cup	1000	774	ball2	1000	1	9851s

Table 29.1: Performance of the function *minkowski_sum_3*.

29.3 Features and Restrictions

This package was written to allow the computation of Minkowski sums of full-dimensional polyhedra even in so-called tight-passage scenarios. Tight passage scenarios occur in robot motion planning, when a robot is just as wide as a passage it needs to traverse. In these scenarios at least one polyhedron—the obstacles or the robot—must be modeled as an open set. Then the Minkowski sum will also be an open set and tight passages will occur as lower-dimensional exclusions, i.e., as facets, lines, or vertices that are, in contrast to the volume around them, not part of the resulting point set. Figure 29.2 shows such a tight passage scenario.

Our implementation uses *Nef_polyhedron_3* to model the input polyhedra and the result polyhedron. An instance of *Nef_polyhedron_3* represents a subdivision of the three-dimensional space into vertices, edges, facets, and volumes. Some of these items form the polyhedron (selected), while others represent the outer volume or holes within the polyhedron (unselected). As an example, the unit cube is the point set $[0, 1]^3$. The smallest subdivision that represents the unit cube has 8 vertices, 12 edges, 6 facets, and 2 volumes. The volumes enclosed by the vertices, edges, and facets is the interior of the cube and therefore selected. The volume outside the cube does not belong to it and is therefore unselected. The vertices, edges, and facets—also denoted as boundary items—are needed to separate the two volumes, but are also useful for representing topological properties. In case of the (closed) unit cube the boundary items are part of the polyhedron and therefore selected, but in case of the open unit cube $[0, 1)^3$ they are unselected. Each item has its own selection mark, which allows the correct representation of Nef polyhedra, which are closed under Boolean and topological operations. Details can be found in the chapter on 3D Boolean operations on Nef polyhedra 27.

The use of *Nef_polyhedron_3* allows many scenarios beyond the Minkowski sum of two solids. First, they can model the input and the result of a tight passage scenario, i.e., they can model open and closed solids as is needed for the input models, and they can model tight passages, which are lower-dimensional exclusions represented as unselected facets, edges, and vertices. We strive for extending the package to work for arbitrary 3D Nef polyhedra. In addition to the Minkowski sums of two solids, we added several features. At the moment we allow an input polyhedron to consist of:

1. singular vertices
2. singular edges
3. singular convex facets without holes
4. surfaces with convex facets that have no holes.
5. three-dimensional features, whose coplanar facets have common selection marks (this includes open and closed solids)

Taking a different viewpoint, the implementation is restricted as follows:

1. The input polyhedra must be bounded (selected outer volume is ignored).
2. All sets of coplanar facets of a full-dimensional feature must have the same selection mark (in case of different selection marks, unselected is assumed).
3. All facets of lower-dimensional features need to be convex and must not have holes (non-convex facets and holes are ignored).

The second restriction might seem a bit odd. It stems from the fact that the Minkowski sum on convex polyhedra can only handle polyhedra, whose sides consist of a single facet. The decomposition process usually yields complex adjacency relations between a convex part, its adjacent convex parts, and the outer volume. The side of a convex piece is then decomposed into several facets, each of which represents one of these adjacency relations. For the convex Minkowski sum, we ignore the decompositions of the sides, but need to find a common selection mark. If there are two facets that are adjacent to the outer volume, but have different selections marks, we cannot set a common selection mark without spoiling the correctness of the Minkowski sum.

29.4 Usage

The function *minkowski_sum_3* should be used with the *Exact_predicates_exact_constructions_kernel*, which often is the most efficient choice and allows floating-point input. Consult Section for more details.

The following example code illustrates the usage of the function *minkowski_sum_3*. Note that either input polyhedra will be modified by the function if it is non-convex. So, if they are needed further on, they need to be copied, first. The copying is not done by the function itself to keep the memory usage as small as possible.

```
#include <CGAL/Exact_predicates_exact_constructions_kernel.h>
#include <CGAL/Nef_polyhedron_3.h>
#include <CGAL/IO/Nef_polyhedron_iostream_3.h>
#include <CGAL/minkowski_sum_3.h>
#include <fstream>
#include <iostream>

typedef CGAL::Exact_predicates_exact_constructions_kernel Kernel;
typedef CGAL::Nef_polyhedron_3<Kernel> Nef_polyhedron;

int main() {

    Nef_polyhedron N0, N1;
    std::ifstream in("cube.nef3");
    in >> N0;
    std::cin >> N1;
    Nef_polyhedron result = CGAL::minkowski_sum_3(N0, N1);
}
```

File: examples/Minkowski_sum_3/cube_offset.cpp

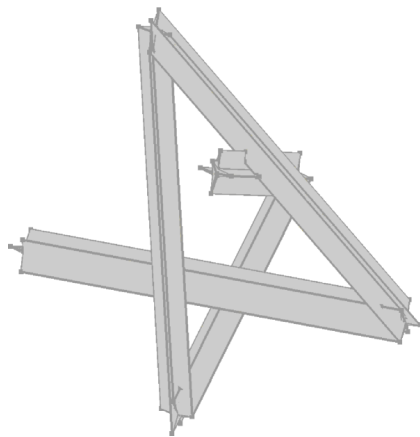

Figure 29.4: The region swept by a star that moves along a polygonal path.

29.5 Glide

With the function *minkowski_sum_3* it is also possible to realize other interesting geometric operations like the glide operation, which computes the point set swept by a polyhedron that moves along a polygonal path. The following example shows how to construct a polygonal path and then compute the glide operation by calling the function *minkowski_sum_3*.

```
#include <CGAL/Exact_predicates_exact_constructions_kernel.h>
#include <CGAL/Nef_polyhedron_3.h>
#include <CGAL/IO/Nef_polyhedron_istream_3.h>
#include <CGAL/minkowski_sum_3.h>
#include <iostream>

typedef CGAL::Exact_predicates_exact_constructions_kernel Kernel;
typedef CGAL::Nef_polyhedron_3<Kernel>      Nef_polyhedron;
typedef Kernel::Point_3 Point_3;
typedef Point_3* point_iterator;
typedef std::pair<point_iterator,point_iterator>
    point_range;
typedef std::list<point_range> polyline;

int main(int argc, char* argv[])
{
    Nef_polyhedron N0;
    std::cin >> N0;
    Point_3 p1[6] =
```

```

    {Point_3(-100,0,0),
      Point_3(40,-70,0),
      Point_3(40,50,40),
      Point_3(-90,-60,60),
      Point_3(0, 0, -100),
      Point_3(30,0,150)
    };

    polyline poly;
    poly.push_back(point_range(pl,pl+6));
    Nef_polyhedron N1(poly.begin(), poly.end(),
      Nef_polyhedron::Polylines_tag());
    Nef_polyhedron result = CGAL::minkowski_sum_3(N0, N1);
}

```

CGAL::minkowski_sum_3

Definition

The function *minkowski_sum_3* computes the Minkowski sum of two given 3D Nef polyhedra *N0* and *N1*. Note that the function runs in $O(n^3 m^3)$ time in the worst case, where *n* and *m* are the complexities of the two input polyhedra (the complexity of a *Nef_polyhedron_3* is the sum of its *Vertices*, *Halfedges* and *SHalfedges*).

Nef_polyhedron_3 *minkowski_sum_3*(*Nef_polyhedron_3* *N0*, *Nef_polyhedron_3* *N1*)

Precondition:

An input polyhedron may consist of:

1. singular vertices
2. singular edges
3. singular convex facets without holes
4. surfaces with convex facets that have no holes.
5. three-dimensional features, whose coplanar facets have common selection marks (this includes open and closed solids)

Taking a different viewpoint, the implementation is restricted as follows:

1. The input polyhedra must be bounded (selected outer volume is ignored).
2. All sets of coplanar facets of a full-dimensional feature must have the same selection mark (in case of different selection marks, unselected is assumed).
3. All facets of lower-dimensional features need to be convex and must not have holes (non-convex facets and holes are ignored).

Postcondition:

If either of the input polyhedra is non-convex, it is modified during the computation, i.e., it is decomposed into convex pieces.

30.1 Introduction

Given a set C of planar curves, the *arrangement* $\mathcal{A}(C)$ is the subdivision of the plane into zero-dimensional, one-dimensional and two-dimensional cells, called *vertices*, *edges* and *faces*, respectively induced by the curves in C . Arrangements are ubiquitous in the computational-geometry literature and have many applications; see, e.g., [AS00, Hal04].

The curves in C can intersect each other (a single curve may also be self-intersecting or may be comprised of several disconnected branches) and are not necessarily x -monotone.¹ We construct a collection C'' of x -monotone subcurves that are pairwise disjoint in their interiors in two steps as follows. First, we decompose each curve in C into maximal x -monotone subcurves (and possibly isolated points), obtaining the collection C' . Note that an x -monotone curve cannot be self-intersecting. Then, we decompose each curve in C' into maximal connected subcurves not intersecting any other curve (or point) in C' . The collection C'' may also contain isolated points, if the curves of C contain such points. The arrangement induced by the collection C'' can be conveniently embedded as a planar graph, whose vertices are associated with curve endpoints or with isolated points, and whose edges are associated with subcurves. It is easy to see that $\mathcal{A}(C) = \mathcal{A}(C'')$. This graph can be represented using a *doubly-connected edge list* data-structure (DCEL for short), which consists of containers of vertices, edges and faces and maintains the incidence relations among these objects.

The main idea behind the DCEL data-structure is to represent each edge using a pair of directed *halfedges*, one going from the xy -lexicographically smaller (left) endpoint of the curve toward its the xy -lexicographically larger (right) endpoint, and the other, known as its *twin* halfedge, going in the opposite direction. As each halfedge is directed, we say it has a *source* vertex and a *target* vertex. Halfedges are used to separate faces, and to connect vertices (with the exception of *isolated vertices*, which are unconnected).

If a vertex v is the target of a halfedge e , we say that v and e are *incident* to each other. The halfedges incident to a vertex v form a circular list oriented in a clockwise order around this vertex. (An isolated vertex has no incident halfedges.)

¹A continuous planar curve C is *x-monotone* if every vertical line intersects it at most once. For example, a non-vertical line segment is always x -monotone and so is the graph of any continuous function $y = f(x)$. For convenience, we treat vertical line segments as *weakly x-monotone*, as there exists a single vertical line that overlaps them. A circle of radius r centered at (x_0, y_0) is not x -monotone, as the vertical line $x = x_0$ intersects it at $(x_0, y_0 - r)$ and at $(x_0, y_0 + r)$.

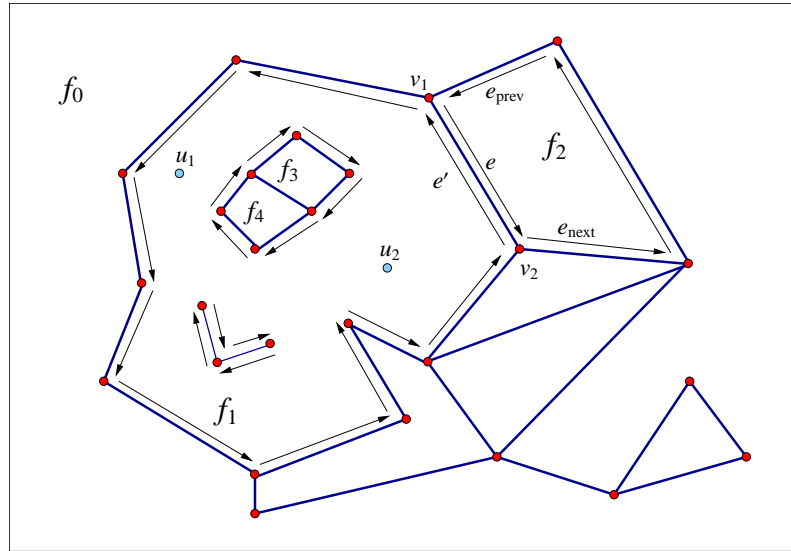

Figure 30.1: An arrangement of interior-disjoint line segments with some of the DCEL records that represent it. The unbounded face f_0 has a single connected component that forms a hole inside it, and this hole is comprised of several faces. The half-edge e is directed from its source vertex v_1 to its target vertex v_2 . This edge, together with its twin e' , correspond to a line segment that connects the points associated with v_1 and v_2 and separates the face f_1 from f_2 . The predecessor e_{prev} and successor e_{next} of e are part of the chain that form the outer boundary of the face f_2 . The face f_1 has a more complicated structure as it contains two holes in its interior: One hole consists of two adjacent faces f_3 and f_4 , while the other hole is comprised of two edges. f_1 also contains two isolated vertices u_1 and u_2 in its interior.

Each halfedge e stores a pointer to its *incident face*, which is the face lying to its left. Moreover, every halfedge is followed by another halfedge sharing the same incident face, such that the target vertex of the halfedge is the same as the source vertex of the next halfedge. The halfedges are therefore connected in circular lists, and form chains, such that all edges of a chain are incident to the same face and wind along its boundary. We call such a chain a *connected component of the boundary* (or *CCB* for short).

The unique CCB of halfedges winding in a counterclockwise orientation along a face boundary is referred to as the *outer CCB* of the face. For the time being let us consider only arrangements of bounded curves, such that exactly one unbounded face exists in every arrangement. The unbounded face does not have an outer boundary. Any other connected component of the boundary of the face is called a *hole* (or *inner CCB*), and can be represented as a circular chain of halfedges winding in a clockwise orientation around it. Note that a hole does not necessarily correspond to a single face, as it may have no area, or alternatively it may consist of several connected faces. Every face can have several holes contained in its interior (or no holes at all). In addition, every face may contain isolated vertices in its interior. See Figure 30.1 for an illustration of the various DCEL features. For more details on the DCEL data structure see [dBvKOS00, Chapter 2].

The rest of this chapter is organized as follows: In Section 30.2 we review in detail the interface of the *Arrangement_2* class-template, which is the central component in the arrangement package. In Section 30.3 we show how queries on an arrangement can be issued. In Section 30.4 we review some important free (global) functions that operate on arrangements, the most important ones being the free insertion-functions. Section 30.6 contains detailed descriptions of the various geometric traits classes included in the arrangement package. Using these traits classes it is possible to construct arrangements of different families of curves. In Section 30.7 we review the notification mechanism that allows external classes to keep track of the changes that an arrangement instance goes through. Section 30.8 explains how to extend the DCEL records, to store extra data with them, and to efficiently update this data. In Section 30.9 we introduce the fundamental operation of overlaying two arrangements. Section 30.10 describes the *Arrangement_with_history_2* class-template that extends the arrange-

ment by storing additional history records with its curves. Finally, in Section 30.11 we review the arrangement input/output functions.

30.2 The Main Arrangement Class

The class `Arrangement_2<Traits,Dcel>` is the main class in the arrangement package. It is used to represent planar arrangements and provides the interface needed to construct them, traverse them, and maintain them. An arrangement is defined by a geometric *traits* class that determines the family of planar curves that form the arrangement, and a DCEL class, which represents the *topological structure* of the planar subdivision. It supplies a minimal set of geometric operations (predicates and constructions) required to construct and maintain the arrangement and to operate on it.

The design of the arrangement package is guided by the need to separate between the representation of the arrangements and the various geometric algorithms that operate on them, and by the need to separate between the topological and geometric aspects of the planar subdivision. The separation is exhibited by the two template parameters of the `Arrangement_2` template:

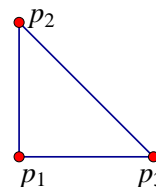

- The *Traits* template-parameter should be instantiated with a model of the *ArrangementBasicTraits_2* concept. The traits class defines the types of *x-monotone* curves and two-dimensional points, *X_monotone_curve_2* and *Point_2* respectively, and supports basic geometric predicates on them.

In the first sections of this chapter we always use `Arr_segment_traits_2` as our traits class, to construct arrangements of line segments. However, the arrangement package contains several other traits classes that can handle also polylines (continuous piecewise-linear curves), conic arcs, and arcs of rational functions. We exemplify the usage of these traits classes in Section 30.6.

- The *Dcel* template-parameter should be instantiated with a class that is a model of the *ArrangementDcel* concept. The value of this parameter is `Arr_default_dcel<Traits>` by default. However, in many applications it is necessary to extend the DCEL features; see Section 30.8 for further explanations and examples.

30.2.1 A Simple Program

The simple program listed below constructs a planar map of three line segments forming a triangle. The constructed arrangement is instantiated with the `Arr_segment_traits_2` traits class to handle segments only. The resulting arrangement consists of two faces, a bounded triangular face and the unbounded face. The program is not very useful as it is, since it ends immediately after the arrangement is constructed. We give more enhanced examples in the rest of this chapter.

```
#include <CGAL/Cartesian.h>
#include <CGAL/MP_Float.h>
#include <CGAL/Quotient.h>
#include <CGAL/Arr_segment_traits_2.h>
#include <CGAL/Arrangement_2.h>

typedef CGAL::Quotient<CGAL::MP_Float>      Number_type;
typedef CGAL::Cartesian<Number_type>        Kernel;
typedef CGAL::Arr_segment_traits_2<Kernel> Traits_2;
typedef Traits_2::Point_2                    Point_2;
typedef Traits_2::X_monotone_curve_2         Segment_2;
```

```

typedef CGAL::Arrangement_2<Traits_2>      Arrangement_2;

int main()
{
    Arrangement_2    arr;
    Segment_2        cv[3];
    Point_2           p1 (0, 0), p2 (0, 4), p3 (4, 0);

    cv[0] = Segment_2 (p1, p2);
    cv[1] = Segment_2 (p2, p3);
    cv[2] = Segment_2 (p3, p1);
    CGAL::insert (arr, &cv[0], &cv[3]);

    return (0);
}

```

30.2.2 Traversing the Arrangement

The simplest and most fundamental arrangement operations are the various traversal methods, which allow users to systematically go over the relevant features of the arrangement at hand.

As mentioned above, the arrangement is represented as a DCEL, which stores three containers of vertices, halfedges and faces. Thus, the *Arrangement_2* class supplies iterators for these containers. For example, the methods *vertices_begin()* and *vertices_end()* return *Arrangement_2::Vertex_iterator* objects that define the valid range of arrangement vertices. The value type of this iterator is *Arrangement_2::Vertex*. Moreover, the vertex-iterator type is equivalent to *Arrangement_2::Vertex_handle*, which serves as a pointer to a vertex. As we show next, all functions related to arrangement features accept handle types as input parameters and return handle types as their output.

In addition to the iterators for arrangement vertices, halfedges and faces, the arrangement class also provides *edges_begin()* and *edges_end()* that return *Arrangement_2::Edge_iterator* objects for traversing the arrangement edges. Note that the value type of this iterator is *Arrangement_2::Halfedge*, representing one of the twin halfedges that represent the edge.

All iterator, circulator² and handle types also have non-mutable (*const*) counterparts. These non-mutable iterators are useful to traverse an arrangement without changing it. For example, the arrangement has a non-constant member function called *vertices_begin()* that returns a *Vertex_iterator* object and another *const* member function that returns a *Vertex_const_iterator* object. In fact, all methods listed in this section that return an iterator, a circulator or a handle have non-mutable counterparts. It should be noted that, for example, *Vertex_handle* can be readily converted into a *Vertex_const_handle*, but not vice-verse.

Conversion of a non-mutable handle to a corresponding mutable handle are nevertheless possible, and can be performed using the static function *Arrangement_2::non_const_handle()* (see, e.g., Section 30.3.1). There are three variant of this function, one for each type of handle.

Traversal Methods for an Arrangement Vertex

A vertex is always associated with a geometric entity, namely with a *Point_2* object, which can be obtained by the *point()* method of the *Vertex* class nested within *Arrangement_2*.

²A *circulator* is used to traverse a circular list, such as the list of halfedges incident to a vertex — see below.

The *is_isolated()* method determines whether a vertex is isolated or not. Recall that the halfedges incident to a non-isolated vertex, namely the halfedges that share a common target vertex, form a circular list around this vertex. The *incident_halfedges()* method returns a circulator of type *Arrangement_2::Halfedge_around_vertex_circulator* that enables the traversal of this circular list in a clockwise direction. The value type of this circulator is *Halfedge*.

The following function prints all the neighbors of a given arrangement vertex (assuming that the *Point_2* type can be inserted into the standard output using the << operator). The arrangement type is the same as in the simple example above.

```
void print_neighboring_vertices (Arrangement_2::Vertex_const_handle v)
{
    if (v->is_isolated()) {
        std::cout << "The vertex (" << v->point() << ") is isolated" << std::endl;
        return;
    }

    Arrangement_2::Halfedge_around_vertex_const_circulator first, curr;
    first = curr = v->incident_halfedges();

    std::cout << "The neighbors of the vertex (" << v->point() << ") are:";
    do {
        // Note that the current halfedge is directed from u to v:
        Arrangement_2::Vertex_const_handle u = curr->source();
        std::cout << " (" << u->point() << ") ";
    } while (++curr != first);
    std::cout << std::endl;
}
```

In case of an isolated vertex, it is possible to obtain the face that contains this vertex using the *face()* method.

Traversal Methods for an Arrangement Halfedge

Each arrangement edge, realized as a pair of twin halfedges, is associated with an *X_monotone_curve_2* object, which can be obtained by the *curve()* method of the *Halfedge* class nested in the *Arrangement_2* class.

The *source()* and *target()* methods return handles to the halfedge source and target vertices respectively. We can obtain a handle to the twin halfedge using the *twin()* method. From the definition of halfedges, it follows that if *he* is a halfedge handle, then:

- *he->curve()* is equivalent to *he->twin()->curve()*,
- *he->source()* is equivalent to *he->twin()->target()*, and
- *he->target()* is equivalent to *he->twin()->source()*.

Every halfedge has an incident face that lies to its left, which can be obtained by the *face()* method. Recall that a halfedge is always one link in a connected chain of halfedges that share the same incident face, known as a *CCB*. The *prev()* and *next()* methods return handles to the previous and next halfedges in the *CCB* respectively.

As the *CCB* is a circular list of halfedges, it is only natural to traverse it using a circulator. The *ccb()* method returns a *Arrangement_2::Ccb_halfedge_circulator* object for the halfedges along the *CCB*.

The function *print_ccb()* listed below prints all *x*-monotone curves along a given CCB (assuming that the *Point_2* and the *X_monotone_curve_2* types can be inserted into the standard output using the `<<` operator).

```
void print_ccb (Arrangement_2::Ccb_halfedge_const_circulator circ)
{
    Ccb_halfedge_const_circulator curr = circ;
    std::cout << "(" << curr->source()->point() << ")";
    do {
        Arrangement_2::Halfedge_const_handle he = curr->handle();
        std::cout << "    [" << he->curve() << "]" << "    "
            << "(" << he->target()->point() << ")";
    } while (++curr != circ);
    std::cout << std::endl;
}
```

Traversal Methods for an Arrangement Face

An arrangement of bounded curves always has a single unbounded face. The function *unbounded_face()* returns a handle to this face. (Note that an empty arrangement contains nothing *but* the unbounded face.)

Given a *Face* object, we can use the *is_unbounded()* method to determine whether it is unbounded. Bounded faces have an outer CCB, and the *outer_ccb()* method returns a circulator for the halfedges along this CCB. Note that the halfedges along this CCB wind in a counterclockwise orientation around the outer boundary of the face.

A face can also contain disconnected components in its interior, namely holes and isolated vertices:

- The *holes_begin()* and *holes_end()* methods return *Arrangement_2::Hole_iterator* iterators that define the range of holes inside the face. The value type of this iterator is *Ccb_halfedge_circulator*, defining the CCB that winds in a clockwise orientation around a hole.
- The *isolated_vertices_begin()* and *isolated_vertices_end()* methods return *Arrangement_2::Isolated_vertex_iterator* iterators that define the range of isolated vertices inside the face. The value type of this iterator is *Vertex*.

The function *print_face()* listed below prints the outer and inner boundaries of a given face, using the function *print_ccb()*, which was introduced in the previous subsection.

```
void print_face (Arrangement_2::Face_const_handle f)
{
    // Print the outer boundary.
    if (f->is_unbounded())
        std::cout << "Unbounded face. " << std::endl;
    else {
        std::cout << "Outer boundary: ";
        print_ccb (f->outer_ccb());
    }

    // Print the boundary of each of the holes.
    Arrangement_2::Hole_const_iterator hi;
    int index = 1;
    for (hi = f->holes_begin(); hi != f->holes_end(); ++hi, ++index) {
```

```

        std::cout << "    Hole #" << index << ": ";
        print_ccb (*hi);
    }

    // Print the isolated vertices.
    Arrangement_2::Isolated_vertex_const_iterator iv;
    for (iv = f->isolated_vertices_begin(), index = 1;
         iv != f->isolated_vertices_end(); ++iv, ++index)
    {
        std::cout << "    Isolated vertex #" << index << ": "
                  << "(" << iv->point() << ")" << std::endl;
    }
}

```

Additional Example

The function listed below prints the current setting of a given arrangement. This concludes the preview of the various traversal methods.³

```

void print_arrangement (const Arrangement_2& arr)
{
    // Print the arrangement vertices.
    Vertex_const_iterator vit;
    std::cout << arr.number_of_vertices() << " vertices:" << std::endl;
    for (vit = arr.vertices_begin(); vit != arr.vertices_end(); ++vit) {
        std::cout << "(" << vit->point() << ")";
        if (vit->is_isolated())
            std::cout << " - Isolated." << std::endl;
        else
            std::cout << " - degree " << vit->degree() << std::endl;
    }

    // Print the arrangement edges.
    Edge_const_iterator eit;
    std::cout << arr.number_of_edges() << " edges:" << std::endl;
    for (eit = arr.edges_begin(); eit != arr.edges_end(); ++eit)
        std::cout << "[" << eit->curve() << "]" << std::endl;

    // Print the arrangement faces.
    Face_const_iterator fit;
    std::cout << arr.number_of_faces() << " faces:" << std::endl;
    for (fit = arr.faces_begin(); fit != arr.faces_end(); ++fit)
        print_face (fit);
}

```

³The file *arr_print.h*, which can be found under the examples folder, includes this function and the rest of the functions listed in this section. Over there they are written in a more generic fashion, where the arrangement type serves as a template parameter for these functions, so different instantiations of the *Arrangement_2<Traits,Dcel>* template can be provided to the same function templates.

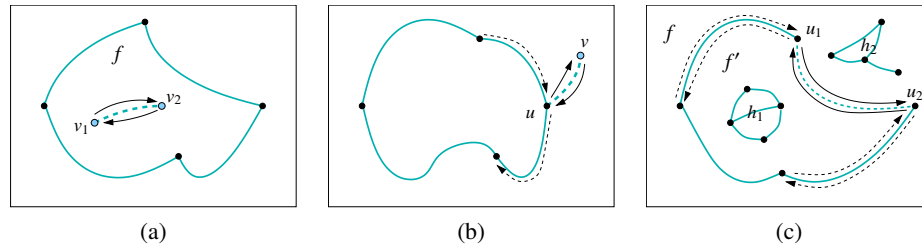

Figure 30.2: The various specialized insertion procedures. The inserted x -monotone curve is drawn with a light dashed line, surrounded by two solid arrows that represent the pair of twin half-edges added to the DCEL. Existing vertices are shown as black dots while new vertices are shown as light dots. Existing half-edges that are affected by the insertion operations are drawn as dashed arrows. (a) Inserting a curve as a new hole inside the face f . (b) Inserting a curve from an existing vertex u that corresponds to one of its endpoints. (c) Inserting an x -monotone curve whose endpoints are the already existing vertices u_1 and u_2 . In our case, the new pair of half-edges close a new face f' , where the hole h_1 , which used to belong to f , now becomes an enclave in this new face.

30.2.3 Modifying the Arrangement

In this section we review the various member functions of the *Arrangement_2* class that allow users to modify the topological structure of the arrangement by introducing new edges or vertices, modifying them, or removing them.

The arrangement member-functions that insert new curves into the arrangement, thus enabling the construction of a planar subdivision, are rather specialized, as they require a-priori knowledge on the location of the inserted curve. Indeed, for most purposes it is more convenient to construct an arrangement using the free (global) insertion-functions.

Inserting Non-Intersecting x -Monotone Curves

The most important functions that allow users to modify the arrangement, and perhaps the most frequently used ones, are the specialized insertion functions of x -monotone curves whose interior is disjoint from any other curve in the existing arrangement and do not contain any vertex of the arrangement. In addition, these function require that the location of the curve in the arrangement is known.

The motivation behind these rather harsh restrictions on the nature of the inserted curves is the decoupling of the topological arrangement representation from the various algorithms that operate on it. While the insertion of an x -monotone curve whose interior is disjoint from all existing arrangement features is quite straightforward (as we show next), inserting curves that intersect with the curves already inserted into the arrangement is much more complicated and requires the application of non-trivial geometric algorithms. These insertion operations are therefore implemented as free functions that operate on the arrangement and the inserted curve(s); see Section 30.4 for more details and examples.⁴

When an x -monotone curve is inserted into an existing arrangement, such that the interior of this curve is disjoint from any arrangement feature, only the following three scenarios are possible, depending on the status of the endpoints of the inserted subcurve:

1. In case both curve endpoints do not correspond to any existing arrangement vertex we have to create two new vertices corresponding to the curve endpoints and connect them using a pair of twin halfedges. This halfedge pair initiates a new hole inside the face that contains the curve in its interior.

⁴You may skip to Section 30.4, and return to this subsection at a later point in time.

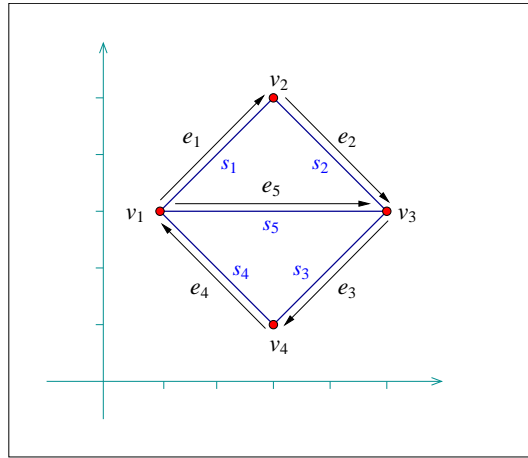

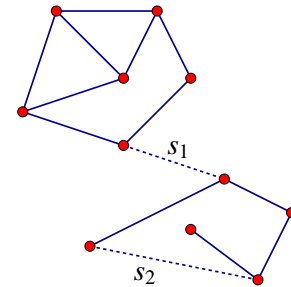

Figure 30.3: The arrangement of the line segments s_1, \dots, s_5 constructed in *edge_insertion.cpp*. The arrows mark the direction of the halfedges returned from the various insertion functions.

2. If exactly one endpoint corresponds to an existing arrangement vertex (we distinguish between a vertex that corresponds to the left endpoint of the inserted curve and a vertex corresponding to its right endpoint), we have to create a new vertex that corresponds to the other endpoint of the curve and to connect the two vertices by a pair of twin halfedges that form an “antenna” emanating from the boundary of an existing connected component (note that if the existing vertex used to be isolated, this operation is actually equivalent to forming a new hole inside the face that contains this vertex).
3. If both endpoints correspond to existing arrangement vertices, we connect these vertices using a pair of twin halfedges. (If one or both vertices are isolated this case reduces to one of the two previous cases respectively.)
The two following subcases may occur:

- Two disconnected components are merged into a single connected component (as is the case with the segment s_1 in the figure to the left).
- A new face is created, a face that splits from an existing arrangement face. In this case we also have to examine the holes and isolated vertices in the existing face and move the relevant ones inside the new face (as is the case with the segment s_2 in the figure to the left).

The *Arrangement_2* class offers insertion functions named *insert_in_face_interior()*, *insert_from_left_vertex()*, *insert_from_right_vertex()* and *insert_at_vertices()* that perform the special insertion procedures listed above. The first function accepts an x -monotone curve c and an arrangement face f that contains this curve in its interior. The other functions accept an x -monotone curve c and handles to the existing vertices that correspond to the curve endpoint(s). Each of the four functions returns a handle to one of the twin halfedges that have been created, where:

- *insert_in_face_interior(c, f)* returns a halfedge directed from the vertex corresponding to the left endpoint of c toward the vertex corresponding to its right endpoint.
- *insert_from_left_vertex(c, v)* and *insert_from_right_vertex(c, v)* returns a halfedge whose source is the vertex v that and whose target is the new vertex that has just been created.
- *insert_at_vertices(c, v1, v2)* returns a halfedge directed from v_1 to v_2 .

The following program demonstrates the usage of the four insertion functions. It creates an arrangement of five line segments, as depicted in Figure 30.3.⁵ As the arrangement is very simple, we use the simple Cartesian kernel of CGAL with integer coordinates for the segment endpoints. We also use the *Arr_segment_traits_2* class that enables the efficient maintenance of arrangements of line segments; see more details on this traits class in Section 30.6. This example, as many others in this chapter, uses some print-utility functions from the file *print_arr.h*; these functions are also listed in Section 30.2.2.

```
#include <CGAL/Simple_cartesian.h>
#include <CGAL/Arr_segment_traits_2.h>
#include <CGAL/Arrangement_2.h>

#include "arr_print.h"

typedef int                                     Number_type;
typedef CGAL::Simple_cartesian<Number_type>    Kernel;
typedef CGAL::Arr_segment_traits_2<Kernel>      Traits_2;
typedef Traits_2::Point_2                      Point_2;
typedef Traits_2::X_monotone_curve_2           Segment_2;
typedef CGAL::Arrangement_2<Traits_2>          Arrangement_2;
typedef Arrangement_2::Vertex_handle            Vertex_handle;
typedef Arrangement_2::Halfedge_handle          Halfedge_handle;

int main ()
{
    Arrangement_2    arr;

    Segment_2        s1 (Point_2 (1, 3), Point_2 (3, 5));
    Segment_2        s2 (Point_2 (3, 5), Point_2 (5, 3));
    Segment_2        s3 (Point_2 (5, 3), Point_2 (3, 1));
    Segment_2        s4 (Point_2 (3, 1), Point_2 (1, 3));
    Segment_2        s5 (Point_2 (1, 3), Point_2 (5, 3));

    Halfedge_handle e1 = arr.insert_in_face_interior (s1,
        arr.unbounded_face());
    Vertex_handle   v1 = e1->source();
    Vertex_handle   v2 = e1->target();
    Halfedge_handle e2 = arr.insert_from_left_vertex (s2, v2);
    Vertex_handle   v3 = e2->target();
    Halfedge_handle e3 = arr.insert_from_right_vertex (s3, v3);
    Vertex_handle   v4 = e3->target();
    Halfedge_handle e4 = arr.insert_at_vertices (s4, v4, v1);
    Halfedge_handle e5 = arr.insert_at_vertices (s5, v1, v3);

    print_arrangement (arr);
    return 0;
}
```

File: examples/Arrangement_on_surface_2/edge_insertion.cpp

Observe that the first line segment is inserted in the interior of the unbounded face. The other line segments are

⁵Notice that in all figures in the rest of this chapter the coordinate axes are drawn only for illustrative purposes and are *not* part of the arrangement.

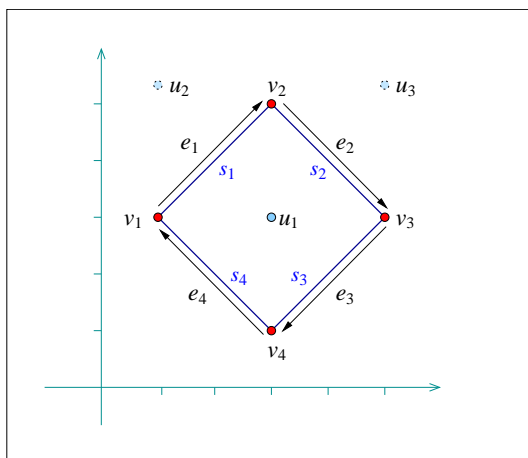

Figure 30.4: An arrangement of line segments containing three isolated vertices, as constructed in *isolated_vertices.cpp*. The vertices u_2 and u_3 are eventually removed from the arrangement.

inserted using the vertices created by the insertion of previous segments. The resulting arrangement consists of three faces, where the two bounded faces form together a hole in the unbounded face.

Manipulating Isolated Vertices

Isolated points are in general simpler geometric entities than curves and indeed the member functions that manipulate them are easier to understand.

The function *insert_in_face_interior*(p, f) inserts an isolated point p , located in the interior of a given face f , into the arrangement and returns a handle to the arrangement vertex it has created and associated with p . Naturally, this function has a precondition that p is really an isolated point, namely it does not coincide with any existing arrangement vertex and does not lie on any edge. As mentioned in Section 30.2.2, it is possible to obtain the face containing an isolated vertex handle v by calling $v \rightarrow \text{face}()$.

The function *remove_isolated_vertex*(v) receives a handle to an isolated vertex and removes it from the arrangement.

The following program demonstrates the usage of the arrangement member-functions for manipulating isolated vertices. It first inserts three isolated vertices located inside the unbounded face, then it inserts four line segments that form a rectangular hole inside the unbounded face (see Figure 30.4 for an illustration). Finally, it traverses the vertices and removes those isolated vertices that are still contained in the unbounded face (u_2 and u_3 in this case):

```
#include <CGAL/Simple_cartesian.h>
#include <CGAL/Arr_segment_traits_2.h>
#include <CGAL/Arrangement_2.h>

#include "arr_print.h"

typedef int                                     Number_type;
typedef CGAL::Simple_cartesian<Number_type>   Kernel;
typedef CGAL::Arr_segment_traits_2<Kernel>     Traits_2;
typedef Traits_2::Point_2                      Point_2;
```

```

typedef Traits_2::X_monotone_curve_2          Segment_2;
typedef CGAL::Arrangement_2<Traits_2>         Arrangement_2;
typedef Arrangement_2::Vertex_handle          Vertex_handle;
typedef Arrangement_2::Halfedge_handle        Halfedge_handle;
typedef Arrangement_2::Face_handle            Face_handle;

int main ()
{
    Arrangement_2    arr;

    // Insert some isolated points:
    Face_handle      uf = arr.unbounded_face();
    Vertex_handle     u1 = arr.insert_in_face_interior (Point_2 (3, 3), uf);
    Vertex_handle     u2 = arr.insert_in_face_interior (Point_2 (1, 5), uf);
    Vertex_handle     u3 = arr.insert_in_face_interior (Point_2 (5, 5), uf);

    // Insert four segments that form a rectangular face:
    Segment_2         s1 (Point_2 (1, 3), Point_2 (3, 5));
    Segment_2         s2 (Point_2 (3, 5), Point_2 (5, 3));
    Segment_2         s3 (Point_2 (5, 3), Point_2 (3, 1));
    Segment_2         s4 (Point_2 (3, 1), Point_2 (1, 3));

    Halfedge_handle   e1 = arr.insert_in_face_interior (s1, uf);
    Vertex_handle      v1 = e1->source();
    Vertex_handle      v2 = e1->target();
    Halfedge_handle   e2 = arr.insert_from_left_vertex (s2, v2);
    Vertex_handle      v3 = e2->target();
    Halfedge_handle   e3 = arr.insert_from_right_vertex (s3, v3);
    Vertex_handle      v4 = e3->target();
    Halfedge_handle   e4 = arr.insert_at_vertices (s4, v4, v1);

    // Remove the isolated vertices located in the unbounded face.
    Arrangement_2::Vertex_iterator    curr_v, next_v;

    for (curr_v = arr.vertices_begin();
         curr_v != arr.vertices_end(); curr_v = next_v)
    {
        // Store an iterator to the next vertex (as we may delete curr_v and
        // invalidate the iterator).
        next_v = curr_v;
        ++next_v;

        if (curr_v->is_isolated() && curr_v->face() == uf)
            arr.remove_isolated_vertex (curr_v);
    }

    print_arrangement (arr);
    return 0;
}

```

File: examples/Arrangement_on_surface_2/isolated_vertices.cpp

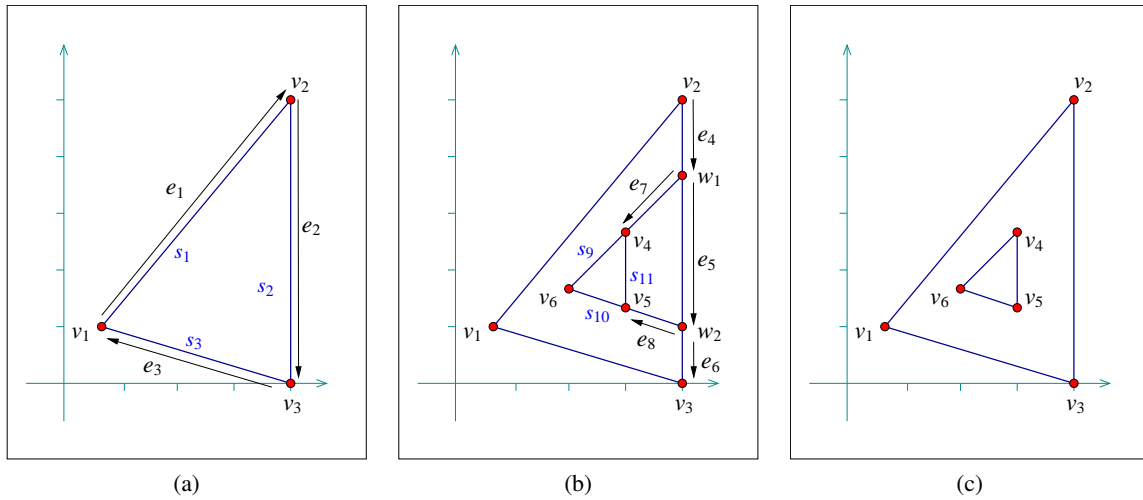

Figure 30.5: An arrangement of line segments as constructed in *edge_manipulation.cpp*. Note that the edges e_7 and e_8 and the vertices w_1 and w_2 , introduced in step (b) are eventually removed in step (c).

Manipulating Halfedges

In the previous subsection we showed how to introduce new isolated vertices in the arrangement. But how does one create a vertex that lies on an existing arrangement edge (more precisely, on an x -monotone curve that is associated with an arrangement edge)?

It should be noted that such an operation involves the splitting of a curve at a given point in its interior, while the traits class used by *Arrangement_2* does not necessarily have the ability to perform such a split operation. However, if users have the ability to split an x -monotone curve into two at a given point p (this is usually the case when employing a more sophisticated traits class; see Section 30.6 for more details) they can use the *split_edge*(e , c_1 , c_2) function, where c_1 and c_2 are the two subcurves resulting from splitting the x -monotone curve associated with the halfedge e at some point (call it p) in its interior. The function splits the halfedge pair into two pairs, both incident to a new vertex v associated with p , and returns a handle to a halfedge whose source equals e 's source vertex and whose target is the new vertex v .

The reverse operation is also possible. Suppose that we have a vertex v of degree 2, whose two incident halfedges, e_1 and e_2 , are associated with the curves c_1 and c_2 . Suppose further that it is possible to merge these two curves into a single continuous x -monotone curve c . Calling *merge_edge*(e_1 , e_2 , c) will merge the two edges into a single edge associated with the curve c , essentially removing the vertex v from the arrangement.

Finally, the function *remove_edge*(e) removes the edge e from the arrangement. Note that this operation is the reverse of an insertion operation, so it may cause a connected component to split into two, or two faces to merge into one, or a hole to disappear. By default, if the removal of e causes one of its end-vertices to become isolated, we remove this vertex as well. However, users can control this behavior and choose to keep the isolated vertices by supplying additional Boolean flags to *remove_edge*() indicating whether the source and the target vertices are to be removed should they become isolated.

In the following example program we show how the edge-manipulation functions can be used. The program works in three steps, as demonstrated in Figure 30.5. Note that here we still stick to integer coordinates, but as we work on a larger scale we use an unbounded integer number-type (in this case, the *Gmpz* type taken from the GMP library) instead of the built-in *int* type.⁶ In case the GMP library is not installed (as indicated

⁶As a rule of thumb, one can use a bounded integer type for representing line segments whose coordinates are bounded by $\lfloor \sqrt[3]{M} \rfloor$, where M is the maximal representable integer value. This guarantees that no overflows occur in the computations carried out by the traits class, hence all traits-class predicates always return correct results.

by the `CGAL_USE_GMP` flag defined in `CGAL/basic.h`), we use `MP_Float`, a number-type included in CGAL's support library that is capable of storing floating-point numbers with unbounded mantissa. We also use the standard Cartesian kernel of CGAL as our kernel. This is recommended when the kernel is instantiated with a more complex number type, as we demonstrate in other examples in this chapter.

```
#include <CGAL/basic.h>

#ifdef CGAL_USE_GMP
#include <CGAL/Gmpz.h>
typedef CGAL::Gmpz                                Number_type;
#else
#include <CGAL/MP_Float.h>
typedef CGAL::MP_Float                            Number_type;
#endif

#include <CGAL/Cartesian.h>
#include <CGAL/Arr_segment_traits_2.h>
#include <CGAL/Arrangement_2.h>

#include "arr_print.h"

typedef CGAL::Cartesian<Number_type>               Kernel;
typedef CGAL::Arr_segment_traits_2<Kernel>         Traits_2;
typedef Traits_2::Point_2                          Point_2;
typedef Traits_2::X_monotone_curve_2               Segment_2;
typedef CGAL::Arrangement_2<Traits_2>              Arrangement_2;
typedef Arrangement_2::Vertex_handle               Vertex_handle;
typedef Arrangement_2::Halfedge_handle             Halfedge_handle;

int main ()
{
    // Step (a) - construct a triangular face.
    Arrangement_2    arr;

    Segment_2        s1 (Point_2 (667, 1000), Point_2 (4000, 5000));
    Segment_2        s2 (Point_2 (4000, 0), Point_2 (4000, 5000));
    Segment_2        s3 (Point_2 (667, 1000), Point_2 (4000, 0));

    Halfedge_handle e1 = arr.insert_in_face_interior (s1,
        arr.unbounded_face());
    Vertex_handle   v1 = e1->source();
    Vertex_handle   v2 = e1->target();
    Halfedge_handle e2 = arr.insert_from_right_vertex (s2, v2);
    Vertex_handle   v3 = e2->target();
    Halfedge_handle e3 = arr.insert_at_vertices (s3, v3, v1);

    // Step (b) - create additional two faces inside the triangle.
    Point_2          p1 (4000, 3666), p2 (4000, 1000);
    Segment_2        s4 (Point_2 (4000, 5000), p1);
    Segment_2        s5 (p1, p2);
    Segment_2        s6 (Point_2 (4000, 0), p2);

    Halfedge_handle e4 = arr.split_edge(e2, s4, Segment_2 (Point_2(4000,
        0), p1));
```

```

Vertex_handle w1 = e4->target();
Halfedge_handle e5 = arr.split_edge (e4->next(), s5, s6);
Vertex_handle w2 = e5->target();
Halfedge_handle e6 = e5->next();

Segment_2 s7 (p1, Point_2 (3000, 2666));
Segment_2 s8 (p2, Point_2 (3000, 1333));
Segment_2 s9 (Point_2 (3000, 2666), Point_2 (2000, 1666));
Segment_2 s10 (Point_2 (3000, 1333), Point_2 (2000, 1666));
Segment_2 s11 (Point_2 (3000, 1333), Point_2 (3000, 2666));

Halfedge_handle e7 = arr.insert_from_right_vertex (s7, w1);
Vertex_handle v4 = e7->target();
Halfedge_handle e8 = arr.insert_from_right_vertex (s8, w2);
Vertex_handle v5 = e8->target();
Vertex_handle v6 = arr.insert_in_face_interior (Point_2 (2000, 1666),
                                                e8->face());

arr.insert_at_vertices (s9, v4, v6);
arr.insert_at_vertices (s10, v5, v6);
arr.insert_at_vertices (s11, v4, v5);

// Step (c) - remove and merge faces to form a single hole in the
// triangle.
arr.remove_edge (e7);
arr.remove_edge (e8);

e5 = arr.merge_edge (e5, e6, Segment_2 (e5->source()->point(),
                                         e6->target()->point()));
e2 = arr.merge_edge (e4, e5, s2);

print_arrangement (arr);
return 0;
}

```

File: examples/Arrangement_on_surface_2/edge_manipulation.cpp

Note how we use the halfedge handles returned from *split_edge()* and *merge_edge()*. Also note the insertion of the isolated vertex v_6 located inside the triangular face (the incident face of e_7). This vertex seizes from being isolated, as it is gets connected to other vertices.

In this context, we should mention the two member functions *modify_vertex(v, p)*, which sets p to be the point associated with the vertex v , and *modify_edge(e, c)*, which sets c to be the x -monotone curve associated with the halfedge e . These functions have preconditions that p is geometrically equivalent to $v->point()$ and c is equivalent to $e->curve()$ (i.e., the two curves have the same graph), respectively, to avoid the invalidation of the geometric structure of the arrangement. At a first glance it may seem as these two functions are of little use. However, we should keep in mind that there may be extraneous data (probably non-geometric) associated with the point objects or with the curve objects, as defined by the traits class. With these two functions we can modify this data; see more details in Section 30.6.

In addition, we can use these functions to replace a geometric object (a point or a curve) with an equivalent object that has a more compact representation. For example, we can replace the point $(\frac{20}{40}, \frac{99}{33})$ associated with some vertex v , by $(\frac{1}{2}, 3)$.

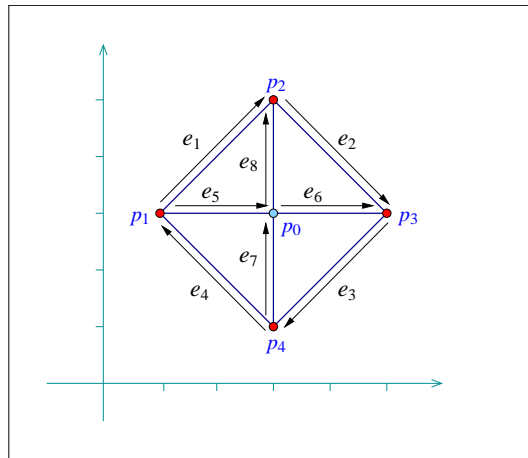

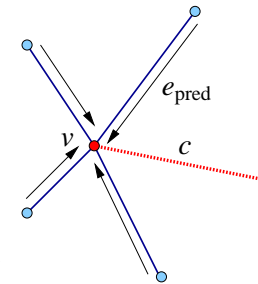

Figure 30.6: An arrangement of line segments, as constructed in *special_edge_insertion.cpp*. Note that p_0 is initially inserted as an isolated point and later on connected to the other four vertices.

advanced

Advanced Insertion Functions

Assume that the specialized insertion function *insert_from_left_vertex*(c, v) is invoked for a curve c , whose left endpoint is already associated with a non-isolated vertex v . Namely, v has already several incident halfedges. It is necessary in this case to locate the exact place for the new halfedge mapped to the inserted new curve c in the circular list of halfedges incident to v . More precisely, it is sufficient to locate one of the halfedges *pred* directed toward v such that c is located between *pred* and *pred*->next() in clockwise order around v , in order to complete the insertion (see Figure 30.2 for an illustration). This may take $O(d)$ time where d is the degree of the vertex. However, if the halfedge *pred* is known in advance, the insertion can be carried out in constant time.

The *Arrangement_2* class provides the advanced versions of the specialized insertion functions for a curve c — namely we have *insert_from_left_vertex*($c, pred$) and *insert_from_right_vertex*($c, pred$) that accept a halfedge *pred* as specified above, instead of a vertex v . These functions are more efficient, as they take constant time and do not perform any geometric operations. Thus, they should be used when the halfedge *pred* is known. In case that the vertex v is isolated or that the predecessor halfedge for the new inserted curve is not known, the simpler versions of these insertion functions should be used.

Similarly, there exist two overrides of the *insert_at_vertices*() function: One that accept the two predecessor halfedges around the two vertices v_1 and v_2 that correspond to the curve endpoints, and one that accepts a handle for one vertex and a predecessor halfedge around the other vertex.

The following program shows how to construct the arrangement depicted in Figure 30.6 using the specialized insertion functions that accept predecessor halfedges:

```
#include <CGAL/Simple_cartesian.h>
#include <CGAL/Arr_segment_traits_2.h>
#include <CGAL/Arrangement_2.h>

#include "arr_print.h"
```

```

        arr.unbounded_face());
    Halfedge_handle  e1 = arr.insert_in_face_interior (s1,
        arr.unbounded_face());
    Halfedge_handle  e2 = arr.insert_from_left_vertex (s2, e1);
    Halfedge_handle  e3 = arr.insert_from_right_vertex (s3, e2);
    Halfedge_handle  e4 = arr.insert_at_vertices (s4, e3, e1->twin());
    Halfedge_handle  e5 = arr.insert_at_vertices (s5, e1->twin(), v0);
    Halfedge_handle  e6 = arr.insert_at_vertices (s6, e5, e3->twin());
    Halfedge_handle  e7 = arr.insert_at_vertices (s7, e4->twin(),
        e6->twin());
    Halfedge_handle  e8 = arr.insert_at_vertices (s8, e5, e2->twin());

    print_arrangement (arr);
    return 0;
}

```

File: examples/Arrangement_on_surface_2/special_edge_insertion.cpp

It is possible to perform even more refined operations on an *Arrangement_2* instance given specific topological information. As most of these operations are very fragile and perform no precondition testing on their input in order to gain efficiency, they are not included in the public interface of the arrangement class. Instead, the *Arr_accessor<Arrangement>* class allows access to these internal arrangement operations — see more details in the Reference Manual.

— advanced —

30.3 Issuing Queries on an Arrangement

One of the most important query types defined on arrangements is the *point-location* query: Given a point, find the arrangement cell that contains it. Typically, the result of a point-location query is one of the arrangement faces, but in degenerate situations the query point can be located on an edge or coincide with a vertex.

Point-location queries are not only common in many applications, they also play an important role in the free insertion-functions (see Section 30.4). Therefore, it is crucial to have the ability to answer such queries effectively for any arrangement instance.

30.3.1 Point-Location Queries

The arrangement package includes several classes (more precisely, class templates parameterized by an arrangement class) that model the *ArrangementPointLocation_2* concept. Namely, they all have a member function called *locate(q)* that accepts a query point *q* and result with a CGAL *Object* that wraps a handle to the arrangement cell containing the query point. This object can be assigned to either a *Face_const_handle*, *Halfedge_const_handle* or a *Vertex_const_handle*, depending on whether the query point is located inside a face, on an edge or on a vertex.

Note that the handles returned by the *locate()* functions are *const* (non-mutable) handles. If necessary, such handles may be casted to mutable handles using the static functions *Arrangement_on_surface_2::non_const_handle()* provided by the arrangement class.

An instance of any point-location class must be attached to an *Arrangement_on_surface_2* instance so we can use it to issue point-location queries. This attachment can be performed when the point-location instance is constructed, or at a later time, using the *init(arr)* method, where *arr* is the attached *Arrangement_on_surface_2* instance. In this chapter we always use the first option.

The following function template, which can be found in the example file *point_location_utils.h*, accepts a point-location object (whose type can be any of the models to the *ArrangementPointLocation_2* concept) and a query point, and prints out the result of the point-location query for the given point. Observe how we use the function *CGAL::assign()* in order to cast the resulting *CGAL::Object* into a handle to an arrangement feature. The point-location object *pl* is assumed to be already associated with an arrangement:

```
template <class PointLocation>
void point_location_query
    (const PointLocation& pl,
     const typename PointLocation::Arrangement_on_surface_2::Point_2& q)
{
    // Perform the point-location query.
    CGAL::Object obj = pl.locate (q);

    // Print the result.
    typedef typename PointLocation::Arrangement_on_surface_2 Arrangement_on_surface_2;

    typename Arrangement_on_surface_2::Vertex_const_handle    v;
    typename Arrangement_on_surface_2::Halfedge_const_handle   e;
    typename Arrangement_on_surface_2::Face_const_handle       f;

    std::cout << "The point " << q << " is located ";
    if (CGAL::assign (f, obj)) {
        // q is located inside a face:
```

```

    if (f->is_unbounded())
        std::cout << "inside the unbounded face." << std::endl;
    else
        std::cout << "inside a bounded face." << std::endl;
}
else if (CGAL::assign (e, obj)) {
    // q is located on an edge:
    std::cout << "on an edge: " << e->curve() << std::endl;
}
else if (CGAL::assign (v, obj)) {
    // q is located on a vertex:
    if (v->is_isolated())
        std::cout << "on an isolated vertex: " << v->point() << std::endl;
    else
        std::cout << "on a vertex: " << v->point() << std::endl;
}
else {
    CGAL_assertion_msg (false, "Invalid object.");
}
}

```

Choosing a Point-Location Strategy

Each of the various point-location classes employs a different algorithm or *strategy*⁷ for answering queries:

- *Arr_naive_point_location*<Arrangement> locates the query point naively, by exhaustively scanning all arrangement cells.
- *Arr_walk_along_a_line_point_location*<Arrangement> simulates a traversal, in reverse order, along an imaginary vertical ray emanating from the query point: It starts from the unbounded face of the arrangement and moves downward toward the query point until locating the arrangement cell containing it.
- *Arr_landmarks_point_location*<Arrangement, Generator> uses a set of “landmark” points whose location in the arrangement is known. Given a query point, it uses a KD-tree to find the nearest landmark and then traverses the straight line segment connecting this landmark to the query point.

There are various ways to select the landmark set in the arrangement, determined by the *Generator* template parameter. By default, the generator class *Arr_landmarks_vertices_generator* is used and the arrangement vertices are the selected landmarks, but other landmark generators, such as sampling random points or choosing points on a grid, are also available; see the Reference Manual for more details.

- *Arr_trapezoid_ric_point_location*<Arrangement> implements Mulmuley’s point-location algorithm [Mul90] (see also [dBvKOS00, Chapter 6]). The arrangement faces are decomposed into simpler cells of constant complexity known as *pseudo-trapezoids* and a search-structure (a directed acyclic graph) is constructed on top of these cells, allowing to locate the pseudo-trapezoid (hence the arrangement cell) containing a query point in expected logarithmic time.

The main advantage of the first two strategies is that they do not require any extra data, so the respective classes just store a pointer to an arrangement object and operate directly on it. Attaching such point-location objects to an existing arrangement has virtually no running-time cost at all, but the query time is linear in the size of the arrangement (the performance of the “walk” strategy is much better in practice, but its worst-case performance

⁷We use the term *strategy* following the design pattern taxonomy [GHJV95].

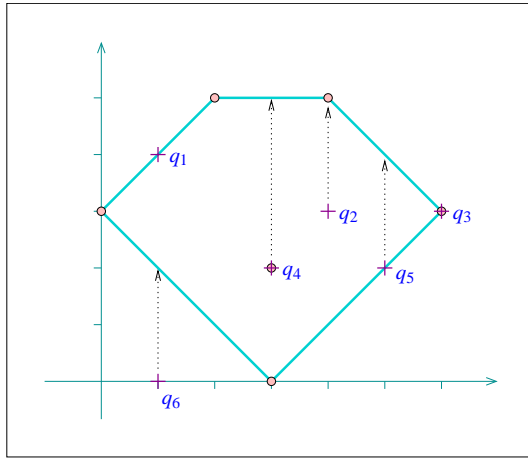

Figure 30.7: The arrangement of line segments, as constructed in *point_location.cpp*, *vertical_ray_shooting.cpp*, and *batched_point_location.cpp*. The arrangement vertices are drawn as small discs, while the query points q_1, \dots, q_6 are marked with crosses.

is linear). Using these strategies is therefore recommended only when a relatively small number of point-location queries are issued by the application, or when the arrangement is constantly changing (i.e., changes in the arrangement structure are more frequent than point-location queries).

On the other hand, the landmarks and the trapezoid RIC strategies require auxiliary data structures on top of the arrangement, which they need to construct once they are attached to an arrangement object and need to keep up-to-date as this arrangement changes. The data structures needed by both strategies can be constructed in $O(N \log N)$ time (where N is the overall number of edges in the arrangement), but the construction needed by the landmark algorithm is in practice significantly faster. In addition, although both resulting data structures are asymptotically linear in size, the KD-tree that the landmark algorithm stores needs significantly less memory. We note that Mulmuley's algorithm guarantees a logarithmic query time, while the query time for the landmark strategy is only logarithmic on average — and we may have scenarios where the query time can be linear. In practice however, the query times of both strategies are competitive. For a detailed experimental comparison, see [HH05]

The main drawback in the current implementation of the landmark strategy, compared to the trapezoidal RIC strategy, is that while the updating the auxiliary data structures related to the trapezoidal decomposition is done very efficiently, the KD-tree maintained by the landmark algorithm needs to be frequently rebuilt as the arrangement changes. In addition, using the landmark point-location class adds some extra requirement from the traits class (that is, the traits class should be a model of a refined concept *ArrangementLandmarkTraits_2*; see Section 30.6 for the details). However, most built-in traits classes that come with the CGAL public release support these extra operations.

It is therefore recommended to use the *Arr_landmarks_point_location* class when the application frequently issues point-location queries on an arrangement that only seldom changes. If the arrangement is more dynamic and is frequently going through changes, the *Arr_trapezoid_ric_point_location* class should be the selected point-location strategy.

An Example

The following program constructs a simple arrangement of five line segments that form a pentagonal face, with a single isolated vertex in its interior, as depicted in Figure 30.7 (the arrangement construction is performed by

the function `construct_segment_arr()` whose listing is omitted here and can be found in `point_location_utils.h`. It then employs the naive and the landmark strategies to issue several point-location queries on this arrangement:

```
#include <CGAL/Simple_cartesian.h>
#include <CGAL/Arr_segment_traits_2.h>
#include <CGAL/Arrangement_2.h>
#include <CGAL/Arr_naive_point_location.h>
#include <CGAL/Arr_landmarks_point_location.h>

#include "point_location_utils.h"

typedef int
    Number_type;
typedef CGAL::Simple_cartesian<Number_type>           Kernel;
typedef CGAL::Arr_segment_traits_2<Kernel>            Traits_2;
typedef Traits_2::Point_2                             Point_2;
typedef CGAL::Arrangement_2<Traits_2>                 Arrangement_2;
typedef CGAL::Arr_naive_point_location<Arrangement_2> Naive_pl;
typedef CGAL::Arr_landmarks_point_location<Arrangement_2> Landmarks_pl;

int main ()
{
    // Construct the arrangement.
    Arrangement_2    arr;
    Naive_pl         naive_pl (arr);
    Landmarks_pl     landmarks_pl;

    construct_segments_arr (arr);

    // Perform some point-location queries using the naive strategy.
    Point_2          q1 (1, 4);
    Point_2          q2 (4, 3);
    Point_2          q3 (6, 3);

    point_location_query (naive_pl, q1);
    point_location_query (naive_pl, q2);
    point_location_query (naive_pl, q3);

    // Attach the landmarks object to the arrangement and perform queries.
    Point_2          q4 (3, 2);
    Point_2          q5 (5, 2);
    Point_2          q6 (1, 0);

    landmarks_pl.attach (arr);

    point_location_query (landmarks_pl, q4);
    point_location_query (landmarks_pl, q5);
    point_location_query (landmarks_pl, q6);

    return 0;
}
```

File: examples/Arrangement_on_surface_2/point_location.cpp

Note that the program uses the auxiliary *point_location_query()* function template to nicely print the result of each query. This function can be found in the header file *point_location_utils.h*.

30.3.2 Vertical Ray Shooting

Another important query issued on arrangements is the vertical ray-shooting query: Given a query point, which arrangement feature do we encounter if we shoot a vertical ray emanating upward (or downward) from this point? In the general case the ray hits an edge, but it is possible that it hits a vertex, or that the arrangement does not have any feature lying directly above (or below) the query point.

All point-location classes listed in the previous section are also models of the *ArrangementVerticalRayShoot_2* concept. That is, they all have member functions called *ray_shoot_up(q)* and *ray_shoot_down(q)* that accept a query point *q* and output a CGAL *Object*. This can be assigned to either a *Halfedge_const_handle* or to a *Vertex_const_handle*. Alternatively, the returned value is a *Face_const_handle* for the unbounded face of the arrangement, in case there is no edge or vertex lying directly above (or below) *q*.

The following function template, *vertical_ray_shooting_query()*, which also located in the header file *point_location_utils.h*, accepts a vertical ray-shooting object, whose type can be any of the models to the *ArrangementVerticalRayShoot_2* concept and prints out the result of the upward vertical ray-shooting operations from a given query point. The ray-shooting object *vrs* is assumed to be already associated with an arrangement:

```
template <class VerticalRayShoot>
void vertical_ray_shooting_query
    (const VerticalRayShoot& vrs,
     const typename VerticalRayShoot::Arrangement_on_surface_2::Point_2& q)
{
    // Perform the point-location query.
    CGAL::Object    obj = vrs.ray_shoot_up (q);

    // Print the result.
    typedef typename VerticalRayShoot::Arrangement_on_surface_2 Arrangement_on_surface_2;

    typename Arrangement_on_surface_2::Vertex_const_handle    v;
    typename Arrangement_on_surface_2::Halfedge_const_handle    e;
    typename Arrangement_on_surface_2::Face_const_handle        f;

    std::cout << "Shooting up from " << q << " : ";
    if (CGAL::assign (e, obj)) {
        // We hit an edge:
        std::cout << "hit an edge: " << e->curve() << std::endl;
    }
    else if (CGAL::assign (v, obj)) {
        // We hit a vertex:
        if (v->is_isolated())
            std::cout << "hit an isolated vertex: " << v->point() << std::endl;
        else
            std::cout << "hit a vertex: " << v->point() << std::endl;
    }
    else if (CGAL::assign (f, obj)) {
```

```

    // We did not hit anything:
    CGAL_assertion (f->is_unbounded());

    std::cout << "hit nothing." << std::endl;
}
else {
    CGAL_assertion_msg (false, "Invalid object.");
}
}

```

The following program uses the auxiliary function listed above to perform vertical ray-shooting queries on an arrangement. The arrangement and the query points are exactly the same as in *point_location.cpp* (see Figure 30.7):

```

#include <CGAL/Cartesian.h>
#include <CGAL/MP_Float.h>
#include <CGAL/Arr_segment_traits_2.h>
#include <CGAL/Arrangement_2.h>
#include <CGAL/Arr_walk_along_line_point_location.h>
#include <CGAL/Arr_trapezoid_ric_point_location.h>

#include "point_location_utils.h"

typedef CGAL::MP_Float
    Number_type;
typedef CGAL::Cartesian<Number_type>           Kernel;
typedef CGAL::Arr_segment_traits_2<Kernel>     Traits_2;
typedef Traits_2::Point_2                      Point_2;
typedef CGAL::Arrangement_2<Traits_2>          Arrangement_2;
typedef CGAL::Arr_walk_along_line_point_location<Arrangement_2> Walk_pl;
typedef CGAL::Arr_trapezoid_ric_point_location<Arrangement_2> Trap_pl;

int main ()
{
    // Construct the arrangement.
    Arrangement_2    arr;
    Walk_pl          walk_pl (arr);
    Trap_pl          trap_pl;

    construct_segments_arr (arr);

    // Perform some vertical ray-shooting queries using the walk strategy.
    Point_2          q1 (1, 4);
    Point_2          q2 (4, 3);
    Point_2          q3 (6, 3);

    vertical_ray_shooting_query (walk_pl, q1);
    vertical_ray_shooting_query (walk_pl, q2);
    vertical_ray_shooting_query (walk_pl, q3);

    // Attach the trapezoid-RIC object to the arrangement and perform
    queries.

```

```

Point_2      q4 (3, 2);
Point_2      q5 (5, 2);
Point_2      q6 (1, 0);

trap_pl.attach (arr);
vertical_ray_shooting_query (trap_pl, q4);
vertical_ray_shooting_query (trap_pl, q5);
vertical_ray_shooting_query (trap_pl, q6);

return 0;
}

```

File: examples/Arrangement_on_surface_2/vertical_ray_shooting.cpp

The number type we use in this example is CGAL's built-in *MP_Float* type which is a floating-point number with an unbounded mantissa and a 32-bit exponent. It supports construction from an integer or from a machine *float* or *double* and performs additions, subtractions and multiplications in an exact number.

30.3.3 Batched Point-Location

Suppose that at a given moment our application has to issue a relatively large number m of point-location queries on a specific arrangement instance. It is possible of course to define a point-location object and to issue separate queries on the arrangement. However, as explained in Section 30.3.1, choosing a simple point-location strategy (either the naive or the walk strategy) means inefficient queries, while the more sophisticated strategies need to construct auxiliary structures that incur considerable overhead in running time.

On the other hand, the arrangement package includes a free *locate()* function that accepts an arrangement a range of query points as its input and sweeps through the arrangement to locate all query points in one pass. The function outputs the query results as pairs, where each pair is comprised of a query point and a CGAL *Object* that represents the cell containing the point (see Section 30.3.1). The output pairs are sorted in increasing *xy*-lexicographical order of the query point.

The batched point-location operation can be performed in $O((m + N) \log(m + N))$ time, where N is the number of edges in the arrangement. This means that when the number m of point-location queries is of the same order of magnitude as N , this operation is more efficient than issuing separate queries. This suggestion is also backed up by experimental results. Moreover, the batched point-location operation is also advantageous as it does not have to construct and maintain additional data structures.

The following program issues a batched point-location query, which is essentially equivalent to the six separate queries performed in *point_location.cpp* (see Section 30.3.1):

```

#include <CGAL/Cartesian.h>
#include <CGAL/MP_Float.h>
#include <CGAL/Arr_segment_traits_2.h>
#include <CGAL/Arrangement_2.h>
#include <CGAL/Arr_batched_point_location.h>
#include <list>

#include "point_location_utils.h"

```

```

typedef CGAL::MP_Float                               Number_type;
typedef CGAL::Cartesian<Number_type>                 Kernel;
typedef CGAL::Arr_segment_traits_2<Kernel>            Traits_2;
typedef Traits_2::Point_2                             Point_2;
typedef CGAL::Arrangement_2<Traits_2>                Arrangement_2;
typedef std::pair<Point_2, CGAL::Object>              Query_result;

int main ()
{
    // Construct the arrangement.
    Arrangement_2 arr;

    construct_segments_arr (arr);

    // Perform a batched point-location query.
    std::list<Point_2> query_points;
    std::list<Query_result> results;

    query_points.push_back (Point_2 (1, 4));
    query_points.push_back (Point_2 (4, 3));
    query_points.push_back (Point_2 (6, 3));
    query_points.push_back (Point_2 (3, 2));
    query_points.push_back (Point_2 (5, 2));
    query_points.push_back (Point_2 (1, 0));

    locate (arr, query_points.begin(), query_points.end(),
            std::back_inserter (results));

    // Print the results.
    std::list<Query_result>::const_iterator res_iter;
    Arrangement_2::Vertex_const_handle v;
    Arrangement_2::Halfedge_const_handle e;
    Arrangement_2::Face_const_handle f;

    for (res_iter = results.begin(); res_iter != results.end();
        ++res_iter) {
        std::cout << "The point (" << res_iter->first << ") is located ";
        if (CGAL::assign (f, res_iter->second)) {
            // The current query point is located inside a face:
            if (f->is_unbounded())
                std::cout << "inside the unbounded face." << std::endl;
            else
                std::cout << "inside a bounded face." << std::endl;
        }
        else if (CGAL::assign (e, res_iter->second)) {
            // The current query point is located on an edge:
            std::cout << "on an edge: " << e->curve() << std::endl;
        }
        else if (CGAL::assign (v, res_iter->second)) {
            // The current query point is located on a vertex:
            if (v->is_isolated())
                std::cout << "on an isolated vertex: " << v->point() <<
std::endl;
            else

```

```

        std::cout << "on a vertex: " << v->point() << std::endl;
    }
}

return 0;
}

```

30.4 Free Functions in the Arrangement Package

In Section 30.2 we reviewed in details the *Arrangement_2* class, which represents two-dimensional subdivisions induced by planar curves, and mentioned that its interface is minimal in the sense that the member functions hardly perform any geometric algorithms and are mainly used for maintaining the topological structure of the subdivision. In this section we explain how to utilize the free (global) functions that operate on arrangements. The implementation of these operations typically require non-trivial geometric algorithms or load some extra requirements on the traits class.

30.4.1 Incremental Insertion Functions

Inserting Non-Intersecting Curves

In Section 30.2 we explained how to construct arrangements of x -monotone curves that are pairwise disjoint in their interior, when the location of the segment endpoints in the arrangement is known. Here we relax this constraint, and allow the location of the inserted x -monotone curve endpoints to be arbitrary, as it may be unknown at the time of insertion. We retain, for the moment, the requirement that the interior of the inserted curve is disjoint from all existing arrangement edges and vertices.

The free function *insert_non_intersecting_curve*(*arr*, *c*, *pl*) inserts the x -monotone curve *c* into the arrangement *arr*, with the precondition that the interior of *c* is disjoint from all *arr*'s existing edges and vertices. The third argument *pl* is a point-location object attached to the arrangement, which is used for performing the insertion. It locates both curve endpoints in the arrangement, where each endpoint is expected to either coincide with an existing vertex or lie inside a face. It is possible to invoke one of the specialized insertion functions (see Section 30.2), based on the query results, and insert *c* at its proper position.⁸ The insertion operation thus hardly requires any geometric operations on top on the ones needed to answer the point-location queries. Moreover, it is sufficient that the arrangement class is instantiated with a traits class that models the *ArrangementBasicTraits_2* concept (or the *ArrangementLandmarkTraits_2* concept, if the landmark point-location strategy is used), which does not have to support the computation of intersection points between curves.

The variant *insert_non_intersecting_curve*(*arr*, *c*) is also available. Instead of accepting a user-defined point-location object, it defines a local instance of the walk point-location class and uses it to insert the curve.

Inserting x -Monotone Curves

The *insert_non_intersecting_curve*() function is very efficient, but its preconditions on the input curves are still rather restricting. Let us assume that the arrangement is instantiated with a traits class that models the refined

⁸The *insert_non_intersecting_curve*() function, as all other functions reviewed in this section, is a function template, parameterized by an arrangement class and a point-location class (a model of the *ArrangementPointLocation_2* concept).

ArrangementXMonotoneTraits_2 concept and supports intersection computations (see Section 30.6 for the exact details). Given an x -monotone curve, it is sufficient to locate its left endpoint in the arrangement and to trace its *zone*, namely the set of arrangement features crossing the curve, until the right endpoint is reached. Each time the new curve c crosses an existing vertex or an edge, the curve is split into subcurves (in the latter case, we have to split the curve associated with the existing halfedge as well) and associate new edges with the resulting subcurves. Recall that an edge is represented by a pair of twin halfedges, so we split it into two halfedge pairs.

The free function *insert(arr, c, pl)* performs this insertion operation. It accepts an x -monotone curve c , which may intersect some of the curves already in the arrangement *arr*, and inserts it into the arrangement by computing its zone. Users may supply a point-location object *pl*, or use the default walk point-location strategy (namely, the variant *insert(arr, c)* is also available). The running-time of this insertion function is proportional to the complexity of the zone of the curve c .

— advanced —

In some cases users may have a prior knowledge of the location of the left endpoint of the x -monotone curve c they wish to insert, so they can perform the insertion without issuing any point-location queries. This can be done by calling *insert(arr, c, obj)*, where *obj* is an object represents the location of c 's left endpoint in the arrangement — namely it wraps a *Vertex_const_handle*, a *Halfedge_const_handle* or a *Face_const_handle* (see also Section 30.3.1).

— advanced —

Inserting General Curves

So far all our examples were of arrangements of line segments, where the *Arrangement_2* template was instantiated with the *Arr_segment_traits_2* class. In this case, the fact that *insert()* accepts an x -monotone curve does not seem to be a restriction, as all line segments are x -monotone (note that we consider vertical line segments to be *weakly* x -monotone).

Suppose that we construct an arrangement of circles. A circle is obviously not x -monotone, so we cannot insert it in the same way we inserted x -monotone curves.⁹ However, it is possible to subdivide each circle into two x -monotone circular arcs (its upper half and its lower half) and to insert each x -monotone arc separately.

The free function *insert()* also supports general curve and not necessarily x -monotone curves. In this case it requires that the traits class used by the arrangement *arr* to be a model of the concept *ArrangementTraits_2*, which refines the *ArrangementXMonotoneTraits_2* concept. It has to define an additional *Curve_2* type (which may differ from the *X_monotone_curve_2* type), and support the subdivision of curves of this new type into x -monotone curves (see the exact details in Section 30.6). The *insert(arr, c, pl)* function performs the insertion of the curve c , which does not need to be x -monotone, into the arrangement by subdividing it (if needed) into x -monotone subcurves and inserting each one separately. Users may supply a point-location object *pl*, or use the default walk point-location strategy by calling *insert(arr, c)*.

Inserting Points

The arrangement class enables us to insert a point as an isolated vertex in a given face. The free function *insert_point(arr, p, pl)* inserts a vertex into *arr* that corresponds to the point p at an arbitrary location. It uses the point-location object *pl* to locate the point in the arrangement (by default, the walk point-location strategy is used), and acts according to the result as follows:

⁹Note that a key operation performed by *insert()* is to locate the left endpoint of the curve in the arrangement. A circle, however, does not have any endpoints!

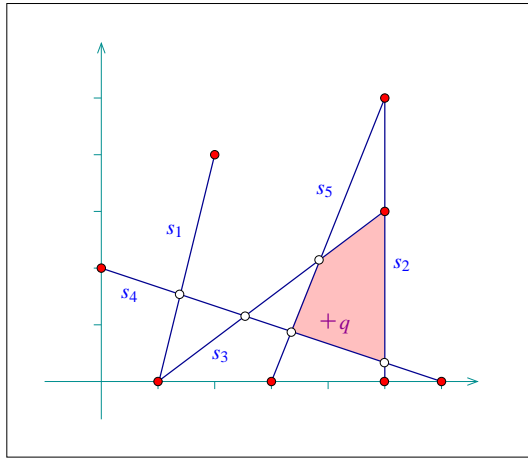

Figure 30.8: An arrangement of five intersecting line segments, as constructed in *incremental_insertion.cpp* and *aggregated_insertion.cpp*. The segment endpoints are marked by black disks and the arrangement vertices that correspond to intersection points are marked by circles. The query point q is marked with a cross and the face that contains it is shaded.

- If p is located inside a face, it is inserted as an isolated vertex inside this face.
- If p lies on an edge, the edge is split to create a vertex associated with p .
- Otherwise, p coincides with an existing vertex and we are done.

In all cases, the function returns a handle to the vertex associated with p .

The arrangement *arr* should be instantiated with a traits class that models the *ArrangementXMonotoneTraits_2* concept, as the insertion operation may involve splitting curves.

An Example

The program below constructs an arrangement of intersecting line-segments. We know that s_1 and s_2 do not intersect, so we use *insert_non_intersecting_curve()* to insert them into the empty arrangement. The rest of the segments are inserted using *insert()*. The resulting arrangement consists of 13 vertices, 16 edges, and 5 faces, as can be seen in Figure 30.8.

In the earlier examples, all arrangement vertices corresponded to segment endpoints. In this example we have additional vertices that correspond to intersection points between two segments. The coordinates of these intersection points are rational numbers, if the input coordinates are rational (or integer). Therefore, the *Quotient<int>* number type is used to represent the coordinates:

```
#include <CGAL/Cartesian.h>
#include <CGAL/Quotient.h>
#include <CGAL/Arr_segment_traits_2.h>
#include <CGAL/Arrangement_2.h>
#include <CGAL/Arr_walk_along_line_point_location.h>

#include "arr_print.h"
```

```

typedef CGAL::Quotient<int>
    Number_type;
typedef CGAL::Cartesian<Number_type>           Kernel;
typedef CGAL::Arr_segment_traits_2<Kernel>      Traits_2;
typedef Traits_2::Point_2                       Point_2;
typedef Traits_2::X_monotone_curve_2            Segment_2;
typedef CGAL::Arrangement_2<Traits_2>           Arrangement_2;
typedef CGAL::Arr_walk_along_line_point_location<Arrangement_2> Walk_pl;

int main ()
{
    // Construct the arrangement of five intersecting segments.
    Arrangement_2  arr;
    Walk_pl        pl(arr);

    Segment_2      s1 (Point_2(1, 0), Point_2(2, 4));
    Segment_2      s2 (Point_2(5, 0), Point_2(5, 5));
    Segment_2      s3 (Point_2(1, 0), Point_2(5, 3));
    Segment_2      s4 (Point_2(0, 2), Point_2(6, 0));
    Segment_2      s5 (Point_2(3, 0), Point_2(5, 5));

    insert_non_intersecting_curve (arr, s1, pl);
    insert_non_intersecting_curve (arr, s2, pl);
    insert (arr, s3, pl);
    insert (arr, s4, pl);
    insert (arr, s5, pl);

    // Print the size of the arrangement.
    std::cout << "The arrangement size:" << std::endl
               << "    V = " << arr.number_of_vertices()
               << ",    E = " << arr.number_of_edges()
               << ",    F = " << arr.number_of_faces() << std::endl;

    // Perform a point-location query on the resulting arrangement and
    print
    // the boundary of the face that contains it.
    Point_2        q (4, 1);
    CGAL::Object    obj = pl.locate (q);

    Arrangement_2::Face_const_handle f;
    CGAL_assertion_code (bool          success =) CGAL::assign (f, obj);

    CGAL_assertion (success);
    std::cout << "The query point (" << q << ") is located in: ";
    print_face<Arrangement_2> (f);

    return 0;
}

```

Other Zone Related Functions

In this section we have described so far free functions that insert curves and points to a given arrangement. Now we will describe functions that don't insert curves or points to an arrangement nor do they change the arrangement, but they are closely related to the incremental insertion functions as they also use the zone algorithm.

The free function *do_intersect()* checks if a given curve or x -monotone curve intersects an existing arrangement's edges or vertices. If the given curve is not an x -monotone curve then the function subdivides the given curve into x -monotone subcurves and isolated vertices. Each subcurve is in turn checked for intersection. The function uses the zone algorithm to check if the curve intersects the arrangement. First, the curve's left endpoint is located. Then, its zone is computed starting from its left endpoint location. The zone computation terminates when an intersection with an arrangement's edge/vertex is found or when the right endpoint is reached. A given point-location object is used for locating the left endpoint of the given curve in the existing arrangement. By default, the function uses the "walk along line" point-location strategy — namely an instance of the class *Arr_walk_along_line_point_location*. If the given curve is x -monotone then the traits class must model the *ArrangementXMonotoneTraits_2* concept. If the curve is not x -monotone curve then the traits class must model the *ArrangementTraits_2* concept.

The *zone()* function computes the zone of a given x -monotone curve in a given arrangement. Meaning, it outputs all the arrangement's elements (vertices, edges and faces) that the x -monotone curve intersects in the order that they are discovered when traversing the x -monotone curve from left to right. The function uses a given point-location object to locate the left endpoint of the given x -monotone curve. By default, the function uses the "walk along line" point-location strategy. The function requires that the traits class will model the *ArrangementXMonotoneTraits_2* concept.

30.4.2 Aggregated Insertion Functions

Let us assume that we have to insert a set of m input curves into an arrangement. It is possible to do this incrementally, inserting the curves one by one, as shown in the previous section. However, the arrangement package provides three free functions that aggregately insert a range of curves into an arrangement:

- *insert_non_intersecting_curves(arr, begin, end)* inserts a range of x -monotone curves given by the input iterators *[begin, end)* into an arrangement *arr*. The x -monotone curves should be pairwise disjoint in their interior and also interior-disjoint from all existing edges and vertices of *arr*.
- *insert(arr, begin, end)* inserts a range of general (not necessarily x -monotone) curves of type *Curve_2* or *X_monotone_curve_2* that may intersect one another, given by the input iterators *[begin, end)*, into the arrangement *arr*.

We distinguish between two cases: (i) The given arrangement *arr* is empty (has only an unbounded face), so we have to construct it from scratch. (ii) We have to insert m input curves to a non-empty arrangement *arr*.

In the first case, we sweep over the input curves, compute their intersection points and construct the DCEL that represents their planar arrangement. This process is performed in $O((m+k)\log m)$ time, where k is the total number of intersection points. The running time is asymptotically better than the time needed for incremental insertion, if the arrangement is relatively sparse (when k is bounded by $\frac{m^2}{\log m}$), but in practice it is recommended to use this aggregated construction process even for dense arrangements, since the sweep-line algorithm needs less geometric operations compared to the incremental insertion algorithms and hence typically runs much faster in practice.

Another important advantage the aggregated insertion functions have is that they do not issue point-location queries. Thus, no point-location object needs to be attached to the arrangement. As explained in Section 30.3.1,

there is a trade-off between construction time and query time in each of the point-location strategies, which affects the running times of the incremental insertion process. Naturally, this trade-off is irrelevant in case of aggregated insertion as above.

The example below shows how to construct the arrangement of line segments depicted in Figure 30.8 and built incrementally in *incremental_insertion.cpp*, as shown in the previous section. We use the aggregated insertion function *insert()* as we deal with line segments. Note that no point-location object needs to be defined and attached to the arrangement:

```
#include <CGAL/Cartesian.h>
#include <CGAL/Quotient.h>
#include <CGAL/Arr_segment_traits_2.h>
#include <CGAL/Arrangement_2.h>
#include <list>

typedef CGAL::Quotient<int>           Number_type;
typedef CGAL::Cartesian<Number_type> Kernel;
typedef CGAL::Arr_segment_traits_2<Kernel> Traits_2;
typedef Traits_2::Point_2            Point_2;
typedef Traits_2::X_monotone_curve_2 Segment_2;
typedef CGAL::Arrangement_2<Traits_2> Arrangement_2;

int main ()
{
    // Construct the arrangement of five intersecting segments.
    Arrangement_2      arr;
    std::list<Segment_2> segments;

    segments.push_back (Segment_2 (Point_2(1, 0), Point_2(2, 4)));
    segments.push_back (Segment_2 (Point_2(5, 0), Point_2(5, 5)));
    segments.push_back (Segment_2 (Point_2(1, 0), Point_2(5, 3)));
    segments.push_back (Segment_2 (Point_2(0, 2), Point_2(6, 0)));
    segments.push_back (Segment_2 (Point_2(3, 0), Point_2(5, 5)));

    insert (arr, segments.begin(), segments.end());

    // Print the size of the arrangement.
    std::cout << "The arrangement size:" << std::endl
              << "    V = " << arr.number_of_vertices()
              << ",    E = " << arr.number_of_edges()
              << ",    F = " << arr.number_of_faces() << std::endl;

    return 0;
}
```

File: examples/Arrangement_on_surface_2/aggregated_insertion.cpp

In case we have to insert a set of m curves into an existing arrangement, where we denote the number of edges in the arrangement by N . As a rule of thumb, if $m = o(\sqrt{N})$, we insert the curves one by one. For larger input sets, we use the aggregated insertion procedures.

In the example below we aggregately construct an arrangement of a set \mathcal{S}_1 containing five line segments. Then we insert a single segment using the incremental insertion function. Finally, we add a set \mathcal{S}_2 with five more

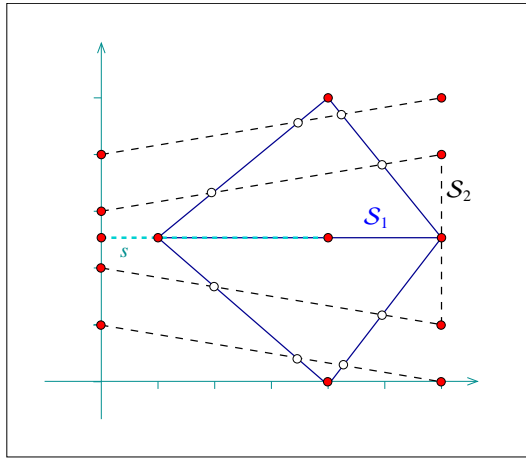

Figure 30.9: An arrangement of intersecting line segments, as constructed in *global_insertion.cpp*. The segments of S_1 are drawn in solid lines and the segments of S_2 are drawn in dark dashed lines. Note that the segment s (light dashed line) overlaps one of the segments in S_1 .

line segments in an aggregated fashion. Notice that the line segments of S_1 are pairwise interior-disjoint, so we use *insert_non_intersecting_curves()*. S_2 also contain pairwise interior-disjoint segments, but as they intersect the existing arrangement, we have to use *insert()* to insert them. Also note that the single segment s we insert incrementally overlaps an existing arrangement edge:

```
#include <CGAL/Cartesian.h>
#include <CGAL/Quotient.h>
#include <CGAL/MP_Float.h>
#include <CGAL/Arr_segment_traits_2.h>
#include <CGAL/Arrangement_2.h>
#include <CGAL/Arr_naive_point_location.h>

#include "arr_print.h"

typedef CGAL::Quotient<CGAL::MP_Float>      Number_type;
typedef CGAL::Cartesian<Number_type>        Kernel;
typedef CGAL::Arr_segment_traits_2<Kernel>   Traits_2;
typedef Traits_2::Point_2                    Point_2;
typedef Traits_2::X_monotone_curve_2         Segment_2;
typedef CGAL::Arrangement_2<Traits_2>        Arrangement_2;
typedef CGAL::Arr_naive_point_location<Arrangement_2> Naive_pl;

int main ()
{
    // Construct the arrangement of five intersecting segments.
    Arrangement_2    arr;
    Segment_2        S1 [5];

    S1[0] = Segment_2 (Point_2 (1, 2.5), Point_2 (4, 5));
    S1[1] = Segment_2 (Point_2 (1, 2.5), Point_2 (6, 2.5));
    S1[2] = Segment_2 (Point_2 (1, 2.5), Point_2 (4, 0));
    S1[3] = Segment_2 (Point_2 (4, 5), Point_2 (6, 2.5));
    S1[4] = Segment_2 (Point_2 (4, 0), Point_2 (6, 2.5));
```

```

insert_non_intersecting_curves (arr, S1, S1 + 5);

// Perform an incremental insertion of a single overlapping segment.
Naive_pl          pl (arr);

insert (arr, Segment_2 (Point_2 (0, 2.5), Point_2 (4, 2.5)), pl);

// Aggregately insert an additional set of five segments.
Segment_2        S2 [5];

S2[0] = Segment_2 (Point_2 (0, 4), Point_2 (6, 5));
S2[1] = Segment_2 (Point_2 (0, 3), Point_2 (6, 4));
S2[2] = Segment_2 (Point_2 (0, 2), Point_2 (6, 1));
S2[3] = Segment_2 (Point_2 (0, 1), Point_2 (6, 0));
S2[4] = Segment_2 (Point_2 (6, 1), Point_2 (6, 4));

insert (arr, S2, S2 + 5);

// Print the size of the arrangement.
std::cout << "The arrangement size:" << std::endl
          << "  V = " << arr.number_of_vertices()
          << ",  E = " << arr.number_of_edges()
          << ",  F = " << arr.number_of_faces() << std::endl;
return 0;
}

```

File: examples/Arrangement_on_surface_2/global_insertion.cpp

The number type used in the example above, *Quotient<MP_Float>*, is comprised of a numerator and a denominator of type *MP_Float*, namely floating-point numbers with unbounded mantissa. This number type is therefore capable of exactly computing the intersection points as long as the segment endpoints are given as floating-point numbers.

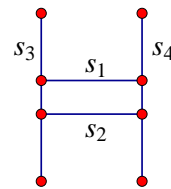

30.4.3 Removing Vertices and Edges

The free functions *remove_vertex()* and *remove_edge()* handle the removal of vertices and edges from an arrangement. The difference between these functions and the member functions of the *Arrangement_2* template having the same name is that they allow the merger of two curves associated with adjacent edges to form a single edge. Thus, they require that the traits class that instantiates the arrangement instance is a model of the refined *ArrangementXMonotoneTraits_2* concept (see Section 30.6).

The function *remove_vertex(arr, v)* removes the vertex *v* from the given arrangement *arr*, where *v* is either an isolated vertex or is a *redundant* vertex — namely, it has exactly two incident edges that are associated with two curves that can be merged to form a single *x*-monotone curve. If neither of the two cases apply, the function returns an indication that it has failed to remove the vertex.

The function *remove_edge(arr, e)* removes the edge *e* from the arrangement by simply calling *arr.remove_edge(e)* (see Section 30.2.3). In addition, if either of the end vertices of *e* becomes isolated or redundant after the removal of the edge, it is removed as well.

The following example demonstrates the usage of the free removal functions. It creates an arrangement of four line segments forming an H-shape with a double horizontal line. Then it removes the two horizontal edges and clears all redundant vertices, such that the final arrangement consists of just two edges associated with the vertical line segments:

```
#include <CGAL/Cartesian.h>
#include <CGAL/Arr_segment_traits_2.h>
#include <CGAL/Arrangement_2.h>
#include <CGAL/Arr_naive_point_location.h>

#include "arr_print.h"

typedef int                                     Number_type;
typedef CGAL::Cartesian<Number_type>          Kernel;
typedef CGAL::Arr_segment_traits_2<Kernel>     Traits_2;
typedef Traits_2::Point_2                     Point_2;
typedef Traits_2::X_monotone_curve_2          Segment_2;
typedef CGAL::Arrangement_2<Traits_2>         Arrangement_2;
typedef Arrangement_2::Vertex_handle           Vertex_handle;
typedef Arrangement_2::Halfedge_handle         Halfedge_handle;
typedef CGAL::Arr_naive_point_location<Arrangement_2> Naive_pl;

int main ()
{
    // Create an arrangement of four line segments forming an H-shape:
    Arrangement_2    arr;
    Naive_pl         pl (arr);

    Segment_2        s1 (Point_2 (1, 3), Point_2 (4, 3));
    Halfedge_handle e1 = arr.insert_in_face_interior (s1,
        arr.unbounded_face());
    Segment_2        s2 (Point_2 (1, 4), Point_2 (4, 4));
    Halfedge_handle e2 = arr.insert_in_face_interior (s2,
        arr.unbounded_face());
    Segment_2        s3 (Point_2 (1, 1), Point_2 (1, 6));
    Segment_2        s4 (Point_2 (4, 1), Point_2 (4, 6));

    insert (arr, s3, pl);
    insert (arr, s4, pl);

    std::cout << "The initial arrangement:" << std::endl;
    print_arrangement (arr);

    // Remove the horizontal edge from the arrangement, and its end
    // vertices:
    Vertex_handle    v1 = e1->source(), v2 = e1->target();
    arr.remove_edge (e1);
    remove_vertex (arr, v1);
    remove_vertex (arr, v2);

    // Remove the second horizontal edge e2 from the arrangement:
    remove_edge (arr, e2);
}
```

```

std::cout << "The final arrangement:" << std::endl;
print_arrangement (arr);
return 0;
}

```

File: examples/Arrangement_on_surface_2/global_removal.cpp

30.5 Arrangements of Unbounded Curves

Previous sections dealt only with arrangements of line segments, namely of bounded curves. Such arrangements always have one unbounded face that contains all other arrangement features. This section explains how to construct arrangements of unbounded curves, such as lines and rays.

30.5.1 Basic Manipulation and Traversal Methods

Consider the arrangement induced by the two lines $y = x$ and $y = -x$. These two lines intersect at the origin, such that the arrangement contains a single vertex $v = (0,0)$, with four infinite rays emanating from it. Each ray corresponds to an arrangement edge, and these edges subdivide the plane into four unbounded faces. Consider a halfedge pair that represents one of the edges. The source vertex of one of these halfedges is v and its target is at infinity, while the other has its source at infinity and v is its target.

If e is an object of the nested type *Arrangement_2::Halfedge*, then the predicates *e.source_at_infinity()* and *e.target_at_infinity()* indicate whether the halfedge represents a curve with an infinite end. In general there is no need to access the source (or the target) of a halfedge if it lies at infinity, since this vertex is not associated with any valid point. Similarly, calling *arr.number_of_vertices()* for an arrangement object *arr* counts only the vertices associated with finite points, and ignores vertices at infinity (and the range [*vertices_begin()*, *vertices_end()*) contains only finite vertices). The method *arr.number_of_vertices_at_infinity()* counts the number of vertices at infinity.

As mentioned above, arrangements of unbounded curves usually have more than one unbounded face. The function *arr.number_of_unbounded_faces()* returns the number of unbounded arrangement faces (Thus, *arr.number_of_faces()* - *arr.number_of_unbounded_faces()* is the number of bounded faces). The functions *arr.unbounded_faces_begin()* and *arr.unbounded_faces_end()* return iterators of type *Arrangement_2::Unbounded_face_iterator* that specify the range of unbounded faces. Naturally, the value-type of this iterator is *Arrangement_2::Face*.

The specialized insertion functions listed in Section 30.2.3 can also be used for inserting x -monotone unbounded curves, provided that they are interior-disjoint from any subcurve that already exists in the arrangement. For example, if you wish to insert a ray r emanating from $(0,0)$ in the direction of $(1,0)$, to the arrangement of $y = -x$ and $y = x$, you can use the function *arr.insert_from_left_vertex()*, as the left endpoint of r is already associated with an arrangement vertex. Other edge-manipulation functions can also be applied on edges associated with unbounded curves.

The following example demonstrates the use of the insertion function for pairwise interior-disjoint unbounded curves. In this example we use the traits class *Arr_linear_traits_2<Kernel>* to instantiate the *Arrangement_2* template. This traits class is capable of representing line segments as well as unbounded linear curves (namely lines and rays). Observe that objects of the type *X_monotone_curve_2* defined by this traits class are constructible from *Line_2*, *Ray_2*, and *Segment_2* objects, as defined in the instantiated kernel.

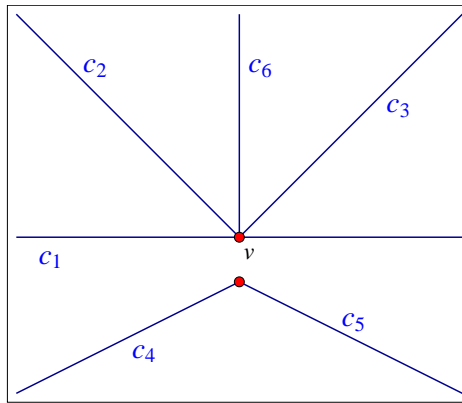

Figure 30.10: An arrangement of unbounded linear objects, as constructed in *unbounded_non_intersecting.cpp*.

The first three curves are inserted using the special insertion functions for x -monotone curves whose location in the arrangement is known. Notice that inserting an unbounded curve in the interior of an unbounded face, or from an existing vertex that represents the bounded end of the curve, may cause an unbounded face to split (this is never the case when inserting a bounded curve — compare with Section 30.2.3). Then, three additional rays are inserted incrementally, using the insertion function for x -monotone curves whose interior is disjoint from all arrangement features. Finally, the program prints the size of the arrangement (compare to the illustration in Figure 30.10) and the outer boundaries of its six unbounded faces:

```
#include <CGAL/Simple_cartesian.h>
#include <CGAL/Arr_linear_traits_2.h>
#include <CGAL/Arrangement_2.h>

typedef int                                     Number_type;
typedef CGAL::Simple_cartesian<Number_type>   Kernel;
typedef CGAL::Arr_linear_traits_2<Kernel>      Traits_2;
typedef Traits_2::Point_2                     Point_2;
typedef Traits_2::Segment_2                   Segment_2;
typedef Traits_2::Ray_2                       Ray_2;
typedef Traits_2::Line_2                     Line_2;
typedef Traits_2::X_monotone_curve_2          X_monotone_curve_2;
typedef CGAL::Arrangement_2<Traits_2>         Arrangement_2;
typedef Arrangement_2::Vertex_handle          Vertex_handle;
typedef Arrangement_2::Halfedge_handle        Halfedge_handle;

int main ()
{
    Arrangement_2    arr;

    // Insert a line in the (currently single) unbounded face of the
    // arrangement,
    // then split it into two at (0,0). Assign v to be the split point.
    X_monotone_curve_2 c1 = Line_2 (Point_2 (-1, 0), Point_2 (1, 0));
    Halfedge_handle    e1 = arr.insert_in_face_interior (c1,

        arr.unbounded_face());

    X_monotone_curve_2 c1_left = Ray_2 (Point_2 (0, 0), Point_2 (-1, 0));
```

```

X_monotone_curve_2 c1_right = Ray_2 (Point_2 (0, 0), Point_2 (1, 0));

e1 = arr.split_edge (e1, c1_left, c1_right);
Vertex_handle      v = e1->target();

CGAL_assertion (! v->is_at_open_boundary());

// Add two more rays using the specialized insertion functions.
X_monotone_curve_2 c2 = Ray_2 (Point_2 (0, 0), Point_2 (-1, 1));
X_monotone_curve_2 c3 = Ray_2 (Point_2 (0, 0), Point_2 (1, 1));

arr.insert_from_right_vertex (c2, v);
arr.insert_from_left_vertex (c3, v);

// Insert three more interior-disjoint rays.
X_monotone_curve_2 c4 = Ray_2 (Point_2 (0, -1), Point_2 (-2, -2));
X_monotone_curve_2 c5 = Ray_2 (Point_2 (0, -1), Point_2 (2, -2));
X_monotone_curve_2 c6 = Ray_2 (Point_2 (0, 0), Point_2 (0, 1));

insert_non_intersecting_curve (arr, c4);
insert_non_intersecting_curve (arr, c5);
insert_non_intersecting_curve (arr, c6);

// Print out the size of the resulting arrangement.
std::cout << "The arrangement size:" << std::endl
           << "   V = " << arr.number_of_vertices()
           << " (plus " << arr.number_of_vertices_at_infinity()
           << " at infinity)"
           << ",   E = " << arr.number_of_edges()
           << ",   F = " << arr.number_of_faces()
           << " (" << arr.number_of_unbounded_faces() << " unbounded)"
           << std::endl << std::endl;

// Print the outer CCBs of the unbounded faces.
Arrangement_2::Face_const_iterator      fit;
Arrangement_2::Ccb_halfedge_const_circulator  first, curr;
Arrangement_2::Halfedge_const_handle      he;
int k = 1;

for (fit = arr.faces_begin(); fit != arr.faces_end(); ++fit, k++) {
    if (! fit->is_unbounded())
        continue;

    std::cout << "Face no. " << k << ": ";
    curr = first = fit->outer_ccb();
    if (! curr->source()->is_at_open_boundary())
        std::cout << "(" << curr->source()->point() << ")";
    do {
        he = curr;
        if (! he->is_fictitious())
            std::cout << " [" << he->curve() << "]"
            << " ";
        else
            std::cout << " [ ... ] ";
    } while (curr = curr->next_ccb());
}

```

```

        if (! he->target()->is_at_open_boundary())
            std::cout << "(" << he->target()->point() << ")";

        ++curr;
    } while (curr != first);
    std::cout << std::endl;

30.5.2 Free Functions

In principle, all queries and operations that relate to arrangements of bounded curves can also be applied to arrangements of unbounded curves. For example, it is possible to issue point-location and vertical ray-shooting queries (see also Section 30.3) on arrangements of lines, where the only restriction is that the query point has finite coordinates.¹⁰

In the following example we show how an arrangement of unbounded lines is utilized to solve the following problem: Given a set of points, does the set contain at least three collinear points? In this example a set of input points is read from a file. The file *points.dat* is used by default. It contains definitions of 100 points randomly selected on the grid $[-10000, 10000] \times [-10000, 10000]$. We construct an arrangement of the dual lines, where the line p^* dual to the point $p = (p_x, p_y)$ is given by the equation $y = p_x * x - p_y$, and check whether three (or more) of the dual lines intersect at a common point, by searching for a (dual) vertex, whose degree is greater than 4. If such a vertex exists, then there are at least three dual lines that intersect at a common point, which implies that there are at least three collinear points.

```

#include "arr_rational_nt.h"
#include <CGAL/Cartesian.h>
#include <CGAL/Arr_linear_traits_2.h>
#include <CGAL/Arrangement_2.h>
#include <cstdlib>

typedef CGAL::Cartesian<Number_type>           Kernel;
typedef CGAL::Arr_linear_traits_2<Kernel>      Traits_2;
typedef Traits_2::Point_2                      Point_2;
typedef Traits_2::Line_2                      Line_2;
typedef Traits_2::X_monotone_curve_2          X_monotone_curve_2;
typedef CGAL::Arrangement_2<Traits_2>         Arrangement_2;

int main (int argc, char *argv[])
{
    // Get the name of the input file from the command line, or use the
    // default
    // points.dat file if no command-line parameters are given.
    const char * filename = (argc > 1) ? argv[1] : "points.dat";
}

```

¹⁰Currently, all point-location strategies except the trapezoidal RIC point-location strategy are capable of handling arrangements of unbounded curves.

```

// Open the input file.
std::ifstream in_file (filename);

if (! in_file.is_open()) {
    std::cerr << "Failed to open " << filename << "!" << std::endl;
    return 1;
}

// Read the points from the file, and consturct their dual lines.
// The input file format should be (all coordinate values are
// integers):
// <n> // number of point.
// <x_1> <y_1> // point #1.
// <x_2> <y_2> // point #2.

    }
}
CGAL_assertion (found_collinear);
return (0);
}

```

File: examples/Arrangement_on_surface_2/dual_lines.cpp

Note that there are no three collinear points among the points defined in the input file *points.dat*. In the second part of the example the existence of collinearity is forced and verified as follows. A line dual to the midpoint of two randomly selected points is introduced, and inserted into the arrangement. This operation is followed by a test that verifies that a vertex of degree greater than 4 exists. This implied that collinearity indeed exists as explained above.

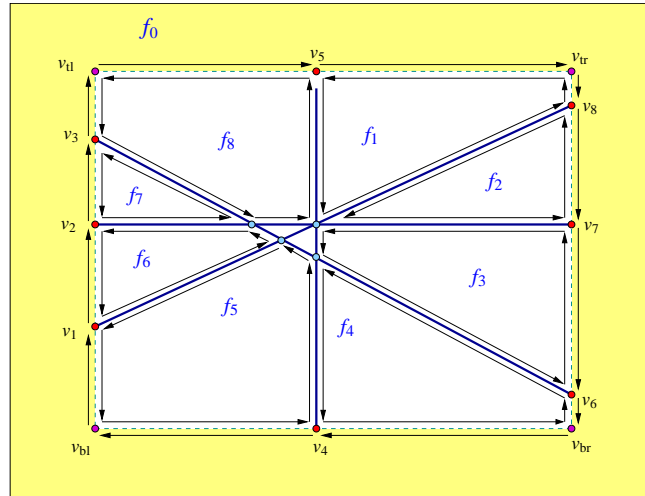

Figure 30.11: A DCEL representing an arrangement of four lines. Halfedges are drawn as thin arrows. The vertices v_1, \dots, v_8 lie at infinity, and are not associated with valid points. The halfedges that connect them are fictitious, and are not associated with concrete curves. The face denoted f_0 (lightly shaded) is the fictitious “unbounded face” which lies outside the imaginary rectangle (dashed) that bounds the actual arrangement. The four fictitious vertices v_{bl}, v_{tl}, v_{br} and v_{tr} represent the four corners of the imaginary bounding rectangle..

30.5.3 Representation of Unbounded Arrangements

Given a set C of unbounded curves, a simple approach for representing the arrangement induced by C would be to clip the unbounded curves using an axis-parallel rectangle that contains all finite curve endpoints and intersection points between curves in C . This process would result in a set C of bounded curves (line segments if C contains lines and rays), and it would be straightforward to compute the arrangement induced by this set. However, we would like to operate directly on the unbounded curves without having to preprocess them. Therefore, we use an implicit bounding rectangle embedded in the DCEL structure. Figure 30.11 shows the arrangement of four lines that subdivide the plane into eight unbounded faces and two bounded ones. Notice that in this case the unbounded faces have outer boundaries, and the halfedges along these outer CCBs are drawn as arrows. The bounding rectangle is drawn with a dashed line. The vertices v_1, v_2, \dots, v_8 , which represent the unbounded ends of the four lines, and lie on the bounding rectangle, actually exist at infinity, and the halfedges connecting them are *fictitious*, and represent portions of the bounding rectangle. Note that the outer CCBs of the unbounded faces contain fictitious halfedges. The twins of these halfedges form together one connected component that corresponds to the entire imaginary rectangle, which forms a single hole in a face \tilde{f} . We say that \tilde{f} is *fictitious*, as it does not corresponds to a real two-dimensional cell of the arrangement.

Observe that there are four extra vertices at infinity that do not lie on any curve; they are denoted as v_{bl}, v_{tl}, v_{br} , and v_{tr} , and represent the bottom-left, top-left, bottom-right, and top-right corners of the bounding rectangle, respectively. Similarly, there are fictitious halfedges that lie on the top, the bottom, the left, or the right edge of the imaginary bounding rectangle. When the arrangement is empty, there are exactly four pairs of fictitious halfedges, that divide the plane into two faces, namely a fictitious face lying outside of the imaginary bounding rectangle and a single unbounded face bounded by the imaginary bounding rectangle.

Summarizing the above, there are four types of arrangement vertices, which differ from one another by their location on the imaginary bounding rectangle:

1. A “normal” vertex, associated with a point in \mathbb{R}^2 whose coordinates are bounded. Such a vertex always lies inside the bounding rectangle.

2. A vertex that represent an unbounded end of an x -monotone curve that is defined at $x = -\infty$ or at $x = \infty$. In case of a horizontal line or a curve with a horizontal asymptote, the y -coordinate of the curve end may be finite (see for example the vertices v_2 and v_7 in Figure 30.11), but in general the curve end also goes to $y = \pm\infty$ (see for instance the vertices v_1 , v_3 , v_6 and v_8 in Figure 30.11). For our convenience, we will always take a “tall” enough bounding rectangle and treat such vertices as lying on either the left or right rectangle edges (that is, if a curve is defined at $x = -\infty$, its left end will be represented by a vertex on the left edge of the bounding rectangle, and if it is defined at $x = \infty$, its right end will be represented by a vertex of the right edge).
3. A vertex that represent the unbounded end of a vertical line or of a curve with a vertical asymptote (finite x -coordinate and an unbounded y -coordinate). Such a vertex always lies on one of the horizontal edges of the bounding rectangle (either the bottom one if $y = -\infty$, or the top one if $y = \infty$). The vertices v_4 and v_5 in Figure 30.11 are of this type.
4. The fictitious vertices that represent the four corners of the imaginary bounding rectangle.

A vertex at infinity of types 1–3 above always has three incident edges: one concrete edge that is associated with an unbounded portion of an x -monotone curve, and two fictitious edges connecting the vertex to its neighboring vertices at infinity. Fictitious vertices (of type 4 above) have exactly two incident edges. See Section 30.6 on how the traits-class interface helps imposing the fact that we never have more than one curve incident to any true vertex at infinity.

The nested types defined in the *Arrangement_2* class support the following methods, in addition to the ones listed in Section 30.2.2:

- The *Vertex* class provides three-valued predicates *boundary_in_x()* and *boundary_in_y()*, which return *NO_BOUNDARY* if the vertex has a finite x -coordinate (or y -coordinate) and *MINUS_INFINITY* or *PLUS_INFINITY* if the vertex lies at infinity. The Boolean predicate *is_at_infinity()* is also supported, where we can access the point associated with a vertex only if it is not a vertex at infinity (recall that a vertex at infinity is not associated with a *Point_2* object).
- The nested *Halfedge* class provides the Boolean predicate *is_fictitious()*. The x -monotone curve associated with a halfedge can be accessed by the *curve()* method only if the halfedge is not fictitious.
- The nested *Face* class provides the Boolean predicate *f.is_fictitious()*. The method *outer_ccb()* has the precondition that the face is not fictitious. Note that valid unbounded faces always have valid CCBs (although this CCB may comprise only fictitious halfedge in case the arrangement contains only bounded curves).

The method *arr.number_of_edges()* does not count the number of fictitious edges, (which is always *arr.number_of_vertices_at_infinity()* + 4), and the iterators returned by *arr.edges_begin()* and *arr.edges_end()* specify a range of valid edges. Similarly, *arr.number_of_faces()* does not count the fictitious face. However, the *Ccb_halfedge_circulator* of the outer boundary of an unbounded face or the *Halfedge_around_vertex_circulator* of a vertex at infinity do traverse fictitious halfedges. For example, it is possible to traverse the outer boundaries of the unbounded arrangement edges using the following procedure:

```
Arrangement_2::Unbounded_face_const_iterator  fit;
Arrangement_2::Ccb_halfedge_const_circulator first, curr;
Arrangement_2::Halfedge_const_handle         he;
int                                           k = 1;

for (fit = arr.unbounded_faces_begin();
    fit != arr.unbounded_faces_end(); ++fit, k++)
{
```

```

std::cout << "Unbounded face no. " << k << ": ";
curr = first = fit->outer_ccb();
if (! curr->source()->is_at_infinity())
    std::cout << "(" << curr->source()->point() << ")";
do
{
    he = curr;
    if (! he->is_fictitious())
        std::cout << "    [" << he->curve() << "]"    ";
    else
        std::cout << "    [ ... ]    ";

    if (! he->target()->is_at_infinity())
        std::cout << "(" << he->target()->point() << ")";

    ++curr;
} while (curr != first);
std::cout << std::endl;
}

```

30.6 Traits Classes

As mentioned in the introduction of this chapter, the traits class encapsulates the definitions of the geometric entities and implements the geometric predicates and constructions needed by the *Arrangement_2* class and by its peripheral algorithms. We also mention throughout the chapter that there are different levels of requirements from the traits class, namely the traits class can model different concept refinement-levels.

30.6.1 The Hierarchy of Traits-Class Concepts

The Basic Concept

A model of the basic concept, *ArrangementBasicTraits_2*, needs to define the types *Point_2* and *X_monotone_curve_2*, where objects of the first type are the geometric mapping of arrangement vertices, and objects of the latter type are the geometric mapping of edges. In addition, it has to support the following set of predicates:

- Compare the x -coordinates of two points p and q .
- Compare two points p and q lexicographically, by their x -coordinates and then (in case of equality) by their y -coordinates.
- Return the left endpoint (similarly, the right endpoint) of an x -monotone curve c .
- Given an x -monotone curve c and a point p that lies in its x -range, determine whether p lies below, above or on c .
- Given two x -monotone curves c_1 and c_2 that share a common left endpoint p , determine whether c_1 lies above or under c_2 immediately to the right of p , or whether the two curves coincide there.
- Check two curves for equality (two curves are equal if their graph is the same).

This basic set of predicates is sufficient for constructing arrangements of bounded x -monotone curves and points that are pairwise disjoint in their interiors and for answering point-location queries and vertical ray-shooting queries. In order to support unbounded curves we add the following predicates, involving curve-ends that coincide with the imaginary boundaries of the arrangement. We say that such curves have *boundary conditions* in x or in y :

- Determine if the left end (similarly, the right end) of an x -monotone curve c has a boundary condition in x . Namely, we say that its boundary condition is *MINUS_INFINITY* if it lies at $x = -\infty$, *PLUS_INFINITY* if it lies at $x = +\infty$, and *NO_BOUNDARY* otherwise.

Similarly, we need a predicate for determining whether a given curve-end (the left end or the right end of a given x -monotone curve) has a boundary condition in y , namely whether it lies at $y = \pm\infty$. Note that we can construct the left endpoint (or the right endpoint) of c only if the corresponding curve-end is bounded (i.e., has no boundary conditions in x or in y).

- Given two x -monotone curve c_1 and c_2 , both defined at $x = -\infty$, determine whether c_1 lies above or under c_2 at $x = -\infty$ (similarly, at $x = \infty$).
- Compare the x -position of an unbounded curve-end with a finite x -coordinate and an infinite y -coordinate with a vertical line that passes through a given query point.
- Compare the x -position of two unbounded curve-ends with finite x -coordinates and infinite y -coordinates.

Each model of the concept *ArrangementBasicTraits_2* needs to define a tag named *Has_boundary_category*, which should be either *Tag_true* or *Tag_false*. In the latter case, the tag marks the fact that the traits class does not support unbounded curves (for example, the *Arr_segment_traits_2* class we have encountered in the previous sections), and it does not have to provide the predicates listed above.

An additional tag, named *Has_left_category*, determines whether the traits class supports the following predicate:

- Given two x -monotone curves c_1 and c_2 that share a common right endpoint p , determine whether c_1 lies above or under c_2 immediately to the left of p , or whether the two curves coincide there.

This predicate is optional, as it can be answered using the other traits-class primitives, and we wish to alleviate the need to implement an extra method that is not absolutely necessary. However, as implementing the predicate directly may prove to be more efficient, the traits-class implementer may choose to provide it. As we will see, the usage of tags makes it easier to implement new traits classes and allows for more flexibility in their design.

The Landmarks Concept

The landmark point-location strategy (see Section 30.3.1) needs its associated arrangement to be instantiated with a model of the refined *ArrangementLandmarkTraits_2* traits concept. A model of this concept must define a fixed precision number type (typically *double*) and support the additional operations:

- Given a point p , approximate the x and y -coordinates of p using the fixed precision number type. We use this operation for approximate computations — there are certain operations in the search for the location of the point that need not be exact and we can perform them faster than other operations.
- Given two points p_1 and p_2 , construct an x -monotone curve connecting p_1 and p_2 .

Supporting Intersecting x -Monotone Curves

A traits class that models the *ArrangementXMonotoneTraits_2* concept, which refines the *ArrangementBasicTraits_2* concept, has to support the following functions:

- Compute all intersection points and overlapping sections of two given x -monotone curves. If possible, compute also the multiplicity of each intersection point.¹¹ Knowing the multiplicity of an intersection point is not required, but it can speed up the arrangement construction.
- Split an x -monotone curve c into two subcurves at a point p lying in the interior of c .
- Given two x -monotone curve c_1 and c_2 that share a common endpoint, determine whether c_1 and c_2 are *mergeable*, that is, whether they can be merged to form a single continuous x -monotone curve of the type supported by the traits class.
- Merge two mergeable x -monotone curve c_1 and c_2 .

Using a model of the *ArrangementXMonotoneTraits_2*, it is possible to construct arrangements of sets of x -monotone curves (and points) that may intersect one another.

Supporting Arbitrary Curves

The concept *ArrangementTraits_2* refines the *ArrangementXMonotoneTraits_2* concept by adding the notion of a general, not necessarily x -monotone (and not necessarily connected) curve. A model of this concept must define the *Curve_2* type and support the division of a curve into a set of continuous x -monotone curves and isolated points. For example, the curve $C : (x^2 + y^2)(x^2 + y^2 - 1) = 0$ is the unit circle (the loci of all points for which $x^2 + y^2 = 1$) with the origin $(0,0)$ as a singular point in its interior. C should therefore be divided into two circular arcs (the upper part and the lower part of the unit circle) and a single isolated point.

Note that the refined model *ArrangementTraits_2* is required only when using the free *insert()* and *insert()* functions (see Section 30.4), which accept a *Curve_2* object in the incremental version, or a range of *Curve_2* objects in the aggregated version. In all other cases it is sufficient to use a model of the *ArrangementXMonotoneTraits_2* concept.

In the rest of this section we review the traits classes included in the public distribution of CGAL, that handle line segments, polylines and conic arcs. The last subsection overviews decorators for geometric traits classes distributed with CGAL, which extend other geometric traits-class by attaching auxiliary data with the geometric objects.

30.6.2 Traits Classes for Line Segments and Linear Objects

The *Arr_segment_traits_2<Kernel>* class used so far in most example programs in this chapter is parameterized by a geometric kernel and uses the *Kernel::Point_2* type as its point type. However, neither the *Curve_2* nor the *X_monotone_curve_2* types are identical to the *Kernel::Segment_2* type. A kernel segment is typically represented by its two endpoints, and these may have a large bit-size representation, if the segment is intersected and split several times (in comparison with the representation of its original endpoints). The large representation may significantly slow down the various traits-class operations involving such a segment. In contrast, the *Arr_segment_traits_2* represents a segment using its supporting line and the two endpoints, such that most

¹¹If the two curves intersect at a point p but have different tangents, p is of multiplicity 1. If the tangents are also equal but their curvatures are not the same, p is of multiplicity 2, etc.

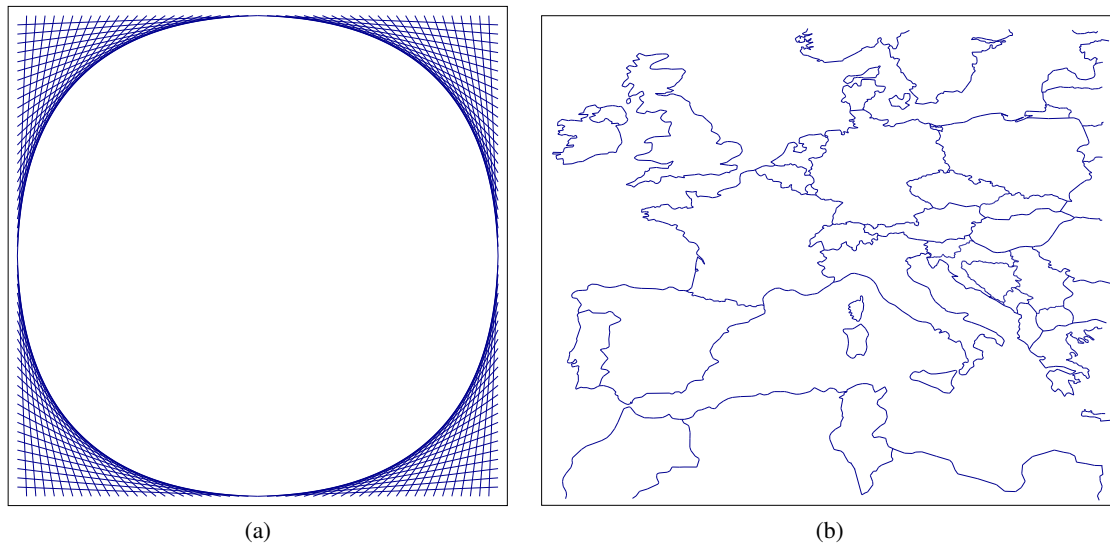

Figure 30.12: (a) An arrangement of 104 line segments from the input file *fan_grids.dat*. (b) An arrangement of more than 3000 interior disjoint line segments, defined in the input file *Europe.dat*.

computations are performed on the supporting line, which never changes as the segment is split. It also caches some additional information with the segment to speed up various predicates. An *X_monotone_curve_2* object can still be constructed from two endpoints or from a kernel segment. Moreover, an *X_monotone_curve_2* instance can also be casted or assigned to a *Kernel::Segment_2* object. The two types are thus fully convertible to one another.

The *Arr_segment_traits_2<Kernel>* class is very efficient for maintaining arrangements of a large number of intersecting line segments, especially if it is instantiated with the appropriate geometric kernel. Using *Cartesian<Gmpq>* as the kernel type is generally a good choice; the coordinates of the segment endpoints are represented as exact rational numbers, and this ensures the robustness and correctness of any computation. However, if the GMP library is not installed, it is possible to use the *Quotient<MP_Float>* number-type, provided by the support library of CGAL, which is somewhat less efficient.¹²

Exact computations are of course less efficient, compared to machine-precision floating-point arithmetic, so constructing an arrangement using the *Cartesian<Gmpq>* kernel (or, similarly, *Cartesian<Quotient<MP_Float>>*) is several times slower in comparison to a *Simple_cartesian<double>* kernel. However, in the latter case the correctness of the computation results is not guaranteed. In many cases it is possible to use *filtered* computations and benefit from both approaches, namely achieve fast running times with guaranteed results. In case we handle a set of line segments that have no degeneracies, namely no two segments share a common endpoint, and no three segments intersect at a common point — or alternatively, degeneracies exist but their number is relatively small — then filtered computation incur only a minor overhead compared to the floating-point arithmetic, while ensuring the correctness of the computation results.

In the following example we use the predefined *Exact_predicates_exact_constructions_kernel* for instantiating our segment-traits class. This kernel use interval arithmetic to filter the exact computations. The program reads a set of line segments with integer coordinates from a file and computes their arrangement. By default it opens the *fan_grids.dat* input-file, located in the examples folder, which contains 104 line segments that form four “fan-like” grids and induce a dense arrangement, as illustrated in Figure 30.12(a):

```
#include <CGAL/Exact_predicates_exact_constructions_kernel.h>
```

¹²Many of the example programs in the rest of the chapter include a header file named *arr_rational_nt.h*, which defines a type named *Number_type* as either *Gmpq* or *Quotient<MP_Float>*, depending on whether GMP is installed or not.

```

#include <CGAL/Arr_segment_traits_2.h>
#include <CGAL/Arrangement_2.h>
#include <CGAL/Timer.h>
#include <list>
#include <fstream>

           << ", E = " << arr.number_of_edges()
           << ", F = " << arr.number_of_faces() << std::endl;

std::cout << "Construction took " << timer.time()
           << " seconds." << std::endl;

return 0;
}

```

File: examples/Arrangement_on_surface_2/predefined_kernel.cpp

The arrangement package also offers a simpler alternative segment-traits class. The traits class *Arr_non_caching_segment_basic_traits_2<Kernel>* models the *ArrangementBasicTraits_2* concept. It uses *Kernel::Point_2* as its point type and *Kernel::Segment_2* as its *x*-monotone curve type. As this traits class does not support intersecting and splitting segments, the kernel representation is sufficient. It is still less efficient than *Arr_segment_traits_2* for constructing arrangements of pairwise disjoint line segments in many cases, as it performs no caching at all, but using this traits class may be preferable as it reduces the memory consumption a bit, since no extra data is stored with the line segments.

The class *Arr_non_caching_segment_traits_2<Kernel>* inherits from *Arr_non_caching_segment_basic_traits_2<Kernel>* and extends it to be a model of the *ArrangementTraits_2* concept. It may thus be used to construct arrangement of intersecting line segments, but as explained above, for efficiency reasons it is recommended to use it only when the arrangement is very sparse and contains hardly any intersection points.

In the following example we read an input file containing a set of line segments that are pairwise disjoint in their interior. As the segments do not intersect, no new points are constructed and we can instantiate the *Arr_non_caching_segment_traits_basic_2<Kernel>* class-template with the predefined *Exact_predicates_inexact_constructions_kernel*. Note that we use the *insert_non_intersecting_curves()* function to construct the arrangement. By default, the example opens the *Europe.dat* input-file, located in the examples folder, which contains more than 3000 line segments with floating-point coordinates that form the map of Europe, as depicted in Figure 30.12(b):

```
#include <CGAL/Exact_predicates_inexact_constructions_kernel.h>
```

```

#include <CGAL/Arr_non_caching_segment_basic_traits_2.h>
#include <CGAL/Arrangement_2.h>
#include <CGAL/Timer.h>
#include <list>
#include <fstream>

typedef CGAL::Exact_predicates_inexact_constructions_kernel   Kernel;
typedef Kernel::FT
    Number_type;
typedef CGAL::Arr_non_caching_segment_basic_traits_2<Kernel>   Traits_2;
typedef Traits_2::Point_2                                       Point_2;
typedef Traits_2::X_monotone_curve_2                            Segment_2;
typedef CGAL::Arrangement_2<Traits_2>
    Arrangement_2;

int main (int argc, char *argv[])
{
    // Get the name of the input file from the command line, or use the
    // default
    // Europe.dat file if no command-line parameters are given.
    const char * filename = (argc > 1) ? argv[1] : "Europe.dat";

    // Open the input file.
    std::ifstream      in_file (filename);

    if (! in_file.is_open()) {
        std::cerr << "Failed to open " << filename << " ..." << std::endl;
        return (1);
    }

    // Read the segments from the file.
    // The input file format should be (all coordinate values are double
    // precision floating-point numbers):
    // <n>                                     // number of segments.
    // <sx_1> <sy_1> <tx_1> <ty_1>           // source and target of segment
    // #1.
    // <sx_2> <sy_2> <tx_2> <ty_2>           // source and target of segment
    // #2.
    // : : : :
    // <sx_n> <sy_n> <tx_n> <ty_n>           // source and target of segment
    // #n.

          << ", E = " << arr.number_of_edges()
          << ", F = " << arr.number_of_faces() << std::endl;

std::cout << "Construction took " << timer.time()
          << " seconds." << std::endl;

return 0;
}

```

File: examples/Arrangement_on_surface_2/predefined_kernel_non_intersecting.cpp

The *Arr_linear_traits_2*<*Kernel*> class used for demonstrating the construction of arrangements of unbounded curves is capable of handling bounded and unbounded linear objects, namely lines, rays and line segments. It is parameterized by a geometric kernel and such that its nested *Point_2* type is the same as the kernel point. The *Curve_2* (and *X_monotone_curve_2*) type it defines is constructible from a *Kernel::Line_2*, a *Kernel::Ray_2* or from a *Kernel::Segment_2* object. Just like the default segment-traits class, the linear-traits class also use caching techniques to speed up its predicates and constructions.

30.6.3 The Polyline-Traits Class

The *Arr_polyline_traits_2*<*SegmentTraits*> class can be used to maintain arrangements of polylines (a.k.a. poly-segments), which are continuous piecewise linear curves. A polyline can be created from a range of points, where the i -th and $(i + 1)$ -st points in the range represent the endpoints of the i -th segment of the polyline. The polyline traits class is parameterized with a segment-traits class that supports the basic operations on segments.

Polylines are the simplest form of a curves that are not necessarily x -monotone. They can be used to approximate more complicated curves in a convenient manner, as the algebra needed to handle them is elementary — rational arithmetic is sufficient to construct an arrangement of polylines in an exact and robust manner. Note, however, that a single polyline can be split into many x -monotone polylines, and that the number of intersection points (or overlapping sections) between two polylines can also be large.

The polyline-traits class is a model of the *ArrangementTraits_2* concept and of the *ArrangementLandmarkTraits_2* concept. It inherits its point type from the segment-traits class, and defines the polyline type, which serves as its *Curve_2*. Polyline curve objects can be constructed from a range of points. They also enable the traversal over the range of defining points, whose first and past-the-end iterators can be obtained through the methods *begin()* and *end()*. The nested *X_monotone_curve_2* type inherits from

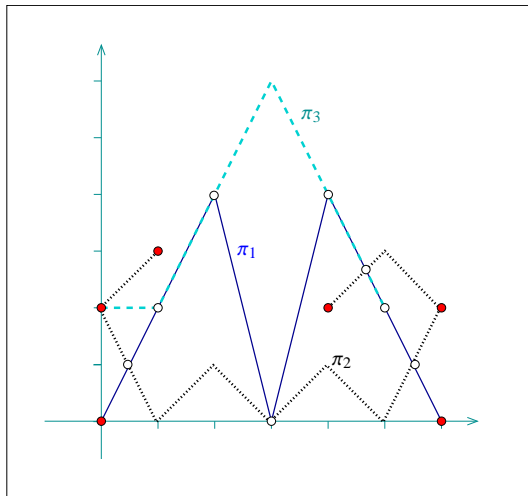

Figure 30.13: An arrangement of three polylines, as constructed in *polylines.cpp*. Disks mark vertices associated with polyline endpoints, while circles mark vertices that correspond to intersection points. Note that π_2 is split into three x -monotone polylines, and that π_1 and π_3 have two overlapping sections.

Curve_2. The points in an x -monotone curve are always stored in lexicographically increasing order of their coordinates.

The following example program constructs an arrangement of three polylines, as depicted in Figure 30.13. Note that most points defining the polylines are not associated with arrangement vertices. The arrangement vertices are either the extreme points of each x -monotone polyline or the intersection points between two polylines:

30.6.4 A Traits Class for Circular Arcs and Line Segments

Circles and circular arcs are the simplest form of non-linear curves. We handle circles whose centers have rational coordinates and whose squared radii is also rational. If we denote the circle center by (x_0, y_0) and its radius by r , then the equation of the circle — that is, $(x - x_0)^2 + (y - y_0)^2 = r^2$ — has rational coefficients. The intersection points of two such circles are therefore solutions of a quadratic equation with rational coefficients, or algebraic numbers of degree 2. The same applies for intersection points between such a rational circle and a line, or a line segment, with rational coefficients (a line whose equation is $ax + by + c = 0$, where a , b and c are rational). Such numbers can be expressed as $\alpha + \beta\sqrt{\gamma}$, where α , β and γ are all rational numbers.

Arrangement of circular arcs and of line segment are very useful, as they occur in many applications. For example, when dilating a polygon by some radius we obtain a shape whose boundary is comprised of line segments, which correspond to dilated polygon edges, and circular arcs, which result from dilated polygon vertices. Using the arrangement of the boundary curves it is possible, for example, to compute the union of a set of dilated polygons.

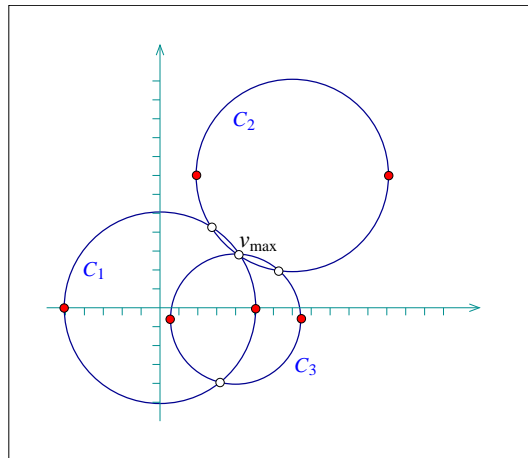

Figure 30.14: An arrangement of three circles constructed in *circles.cpp*. Each circle is split into two x -monotone circular arcs, whose endpoints are drawn as disks. Circles mark vertices that correspond to intersection points. The vertex v_{\max} is a common intersection point of all three circles.

The `Arr_circle_segment_traits_2<Kernel>` class-template is designed for efficient handling of arrangements of circular arcs and line segments. It is parameterized by a geometric kernel, and can handle arrangements of segments of `Kernel::Circle_2` objects (full circles are also supported) or of `Kernel::Line_2` objects — namely circular arcs and line segments. It is important to observe that the nested `Point_2` type defined by the traits class, whose coordinates are typically algebraic numbers of degree 2, is *not* the same as the `Kernel::Point_2` type, which is capable of representing a point with rational coordinates. The coordinates of a point are represented using the nested `CoordNT` number-type.

In the following example an arrangement of three full circles is constructed, as shown in Figure 30.14. Then, the vertex of maximal degree is searched for. The geometric mapping of this vertex is the point $(4,3)$, as all three circles intersect at this point and the associated vertex has six incident edges:

```
#include "arr_rational_nt.h"
#include <CGAL/Cartesian.h>
#include <CGAL/Arr_circle_segment_traits_2.h>
#include <CGAL/Arrangement_2.h>

typedef CGAL::Cartesian<Number_type>      Kernel;
typedef Kernel::Circle_2                  Circle_2;
typedef CGAL::Arr_circle_segment_traits_2<Kernel> Traits_2;
typedef Traits_2::CoordNT                 CoordNT;
typedef Traits_2::Point_2                 Point_2;
typedef Traits_2::Curve_2                 Curve_2;
typedef CGAL::Arrangement_2<Traits_2>     Arrangement_2;

int main ()
{
    // Create a circle centered at the origin with radius 5.
    Kernel::Point_2  c1 = Kernel::Point_2 (0, 0);
    Number_type      sqr_r1 = Number_type (25);      // = 5^2
    Circle_2         circl = Circle_2 (c1, sqr_r1, CGAL::CLOCKWISE);
    Curve_2          cv1 = Curve_2 (circl);
```

```

// Create a circle centered at (7,7) with radius 5.
Kernel::Point_2  c2 = Kernel::Point_2 (7, 7);
Number_type      sqr_r2 = Number_type (25);      // = 5^2
Circle_2         circ2 = Circle_2 (c2, sqr_r2, CGAL::CLOCKWISE);
Curve_2          cv2 = Curve_2 (circ2);

// Create a circle centered at (4,-0.5) with radius 3.5 (= 7/2).
Kernel::Point_2  c3 = Kernel::Point_2 (4, Number_type (-1,2));
Number_type      sqr_r3 = Number_type (49, 4);    // = 3.5^2
Circle_2         circ3 = Circle_2 (c3, sqr_r3, CGAL::CLOCKWISE);
Curve_2          cv3 = Curve_2 (circ3);

// Construct the arrangement of the three circles.
Arrangement_2    arr;

insert (arr, cv1);
insert (arr, cv2);
insert (arr, cv3);

// Locate the vertex with maximal degree.
Arrangement_2::Vertex_const_iterator vit;
Arrangement_2::Vertex_const_handle   v_max;
unsigned int                          max_degree = 0;

for (vit = arr.vertices_begin(); vit != arr.vertices_end(); ++vit) {
    if (vit->degree() > max_degree) {
        v_max = vit;
        max_degree = vit->degree();
    }
}

std::cout << "The vertex with maximal degree in the arrangement is: "
           << "v_max = (" << v_max->point() << ") "
           << "with degree " << max_degree << "." << std::endl;
return 0;
}

```

File: examples/Arrangement_on_surface_2/circles.cpp

The *Curve_2* type nested in *Arr_circle_segment_traits_2* can be used to represent circles, circular arcs, or line segments. Curve objects can therefore be constructed from a *Kernel::Circle_2* object or from a *Kernel::Segment_2* object. A circular arc is typically defined by a supporting circle and two endpoints, where the endpoints are instances of the *Point_2* type, with rational or irrational coordinates. The orientation of the arc is determined by the orientation of the supporting circle. Similarly, we also support the construction of lines segments given their supporting line (of type *Kernel::Line_2*) and two endpoints, which may have irrational coordinates (unlike the *Kernel::Segment_2* type).

Note that the *Kernel::Circle_2* type represents a circle whose *squared radius* is rational, where the radius itself may be irrational. However, if the radius is known to be rational, it is advisable to use it, for efficiency reasons. It is therefore also possible to construct a circle, or a circular arc specifying the circle center (a *Kernel::Point_2*), its rational radius, and its orientation. Finally, we also support the construction of a circular arcs that is defined by two endpoints and an arbitrary midpoint that lies on the arc in between its endpoint. In this case, all three points are required to have rational coordinates (to be kernel points).

The following example demonstrates the usage of the various construction methods for circular arcs and line segments. Note the usage of the constructor of *CoordNT* (*alpha*, *beta*, *gamma*), which creates a degree-2 algebraic number whose value is $\alpha + \beta\sqrt{\gamma}$.

```
#include "arr_rational_nt.h"
#include <CGAL/Cartesian.h>
#include <CGAL/Arr_circle_segment_traits_2.h>
#include <CGAL/Arrangement_2.h>

typedef CGAL::Cartesian<Number_type>      Kernel;
typedef Kernel::Circle_2                  Circle_2;
typedef Kernel::Segment_2                 Segment_2;
typedef CGAL::Arr_circle_segment_traits_2<Kernel> Traits_2;
typedef Traits_2::CoordNT                 CoordNT;
typedef Traits_2::Point_2                 Point_2;
typedef Traits_2::Curve_2                 Curve_2;
typedef CGAL::Arrangement_2<Traits_2>     Arrangement_2;

int main ()
{
    std::list<Curve_2>  curves;

    // Create a circle centered at the origin with squared radius 2.
    Kernel::Point_2  c1 = Kernel::Point_2 (0, 0);
    Circle_2         circl = Circle_2 (c1, Number_type (2));

    curves.push_back (Curve_2 (circl));

    // Create a circle centered at (2,3) with radius 3/2 - note that
    // as the radius is rational we use a different curve constructor.
    Kernel::Point_2  c2 = Kernel::Point_2 (2, 3);

    curves.push_back (Curve_2 (c2, Number_type(3, 2)));

    // Create a segment of the line (y = x) with rational endpoints.
    Kernel::Point_2  s3 = Kernel::Point_2 (-2, -2);
    Kernel::Point_2  t3 = Kernel::Point_2 (2, 2);
    Segment_2        seg3 = Segment_2 (s3, t3);

    curves.push_back (Curve_2 (seg3));

    // Create a line segment with the same supporting line (y = x), but
    // having one endpoint with irrational coefficients.
    CoordNT          sqrt_15 = CoordNT (0, 1, 15); // = sqrt(15)
    Point_2          s4 = Point_2 (3, 3);
    Point_2          t4 = Point_2 (sqrt_15, sqrt_15);

    curves.push_back (Curve_2 (seg3.supporting_line(), s4, t4));

    // Create a circular arc that correspond to the upper half of the
    // circle centered at (1,1) with squared radius 3. We create the
    // circle with clockwise orientation, so the arc is directed from
    // (1 - sqrt(3), 1) to (1 + sqrt(3), 1).
    Kernel::Point_2  c5 = Kernel::Point_2 (1, 1);
```

```

Circle_2      circ5 = Circle_2 (c5, 3, CGAL::CLOCKWISE);
CoordNT       one_minus_sqrt_3 = CoordNT (1, -1, 3);
CoordNT       one_plus_sqrt_3 = CoordNT (1, 1, 3);
Point_2       s5 = Point_2 (one_minus_sqrt_3, CoordNT (1));
Point_2       t5 = Point_2 (one_plus_sqrt_3, CoordNT (1));

curves.push_back (Curve_2 (circ5, s5, t5));

// Create a circular arc of the unit circle, directed clockwise from
// (-1/2, sqrt(3)/2) to (1/2, sqrt(3)/2). Note that we orient the
// supporting circle accordingly.
Kernel::Point_2 c6 = Kernel::Point_2 (0, 0);
CoordNT       sqrt_3_div_2 = CoordNT (0, Number_type(1,2), 3);
Point_2       s6 = Point_2 (Number_type (-1, 2), sqrt_3_div_2);
Point_2       t6 = Point_2 (Number_type (1, 2), sqrt_3_div_2);

curves.push_back (Curve_2 (c6, 1, CGAL::CLOCKWISE, s6, t6));

// Create a circular arc defined by two endpoints and a midpoint,
// all having rational coordinates. This arc is the upper-right
// quarter of a circle centered at the origin with radius 5.
Kernel::Point_2 s7 = Kernel::Point_2 (0, 5);
Kernel::Point_2 mid7 = Kernel::Point_2 (3, 4);
Kernel::Point_2 t7 = Kernel::Point_2 (5, 0);

curves.push_back (Curve_2 (s7, mid7, t7));

// Construct the arrangement of the curves.
Arrangement_2  arr;

insert (arr, curves.begin(), curves.end());

// Print the size of the arrangement.
std::cout << "The arrangement size:" << std::endl
          << "   V = " << arr.number_of_vertices()
          << ",   E = " << arr.number_of_edges()
          << ",   F = " << arr.number_of_faces() << std::endl;

return 0;
}

```

File: examples/Arrangement_on_surface_2/circular_arcs.cpp

It is also possible to construct x -monotone curve objects, which represent x -monotone circular arcs or line segments, using similar constructors. Construction from a full circle is obviously not supported. See the Reference Manual for more details.

The traits class-template `Arr_circular_line_arc_traits_2<CircularKernel>` offered by the arrangement package also handles circular arcs and line segments. It is an alternative to the `Arr_circle_segment_traits_2<Kernel>` class-template. These two class templates, while serve similar purposes, are based on different concepts, and posses different characteristics. You are encouraged to experiment with both, compare their performance, and use the most suitable for your case.

30.6.5 A Traits Class for Conic Arcs

A *conic curve* is an algebraic curve of degree 2. Namely, it is the locus of all points (x,y) satisfying the equation $C: rx^2 + sy^2 + txy + ux + vy + w = 0$, where the six coefficients $\langle r, s, t, u, v, w \rangle$ completely characterize the curve. The sign of the expression $\Delta_C = 4rs - t^2$ determines the type of curve:

- If $\Delta_C > 0$ the curve is an ellipse. A circle is a special case of an ellipse, where $r = s$ and $t = 0$.
- If $\Delta_C = 0$ the curve is a parabola — an unbounded conic curve with a single connected branch. When $r = s = t = 0$ we have a line, which can be considered as a degenerate parabola.
- If $\Delta_C < 0$ the curve is a hyperbola. That is, it is comprised of two disconnected unbounded branches.

As the arrangement package is suitable for bounded curves, we consider bounded segments of conic curves, referred to as *conic arcs*. A conic arc a may be either (i) a full ellipse, or (ii) defined by the tuple $\langle C, p_s, p_t, o \rangle$, where C is a conic curve and p_s and p_t are two points on C (namely $C(p_s) = C(p_t) = 0$) that define the *source* and *target* of the arc, respectively. The arc is formed by traversing C from the source to the target going in the orientation specified by o , which is typically clockwise or counterclockwise orientation (but may also be collinear in case of degenerate conic curves).

We always assume that the conic coefficients $\langle r, s, t, u, v, w \rangle$ are rational. When dealing with linear curves (line segments and polylines), similar assumptions guarantee that all intersection points also have rational coordinates, such that the arrangement of such curves can be constructed and maintained using only rational arithmetic. Unfortunately, this does not hold for conic curves, as the coordinates of intersection points of two conic curves with rational coefficients are in general algebraic numbers of degree 4.¹³ In addition, conic arcs may not necessarily be x -monotone, and must be split at points where the tangent to the arc is vertical. In the general case, such points typically have coordinates that are algebraic numbers of degree 2. It is therefore clear that we have to use different number types to represent the conic coefficients and the point coordinates. Note that as arrangement vertices induced by intersection points and points with vertical tangents are likely to have algebraic coordinates, we also allow the original endpoints of the input arcs p_s and p_t to have algebraic coordinates.

The `Arr_conic_traits_2<RatKernel, AlgKernel, NtTraits>` class template is designed for efficient handling of arrangements of bounded conic arcs. The template has three parameters, defined as follows:

- The `RatKernel` class is a geometric kernel, whose field type is an exact rational type. It is used to define basic geometric entities (e.g., a line segment or a circle) with rational coefficients. Typically we use one of the standard CGAL kernels, instantiated with the number type `NtTraits::Rational` (see below).
- The `AlgKernel` class is a geometric kernel whose field type is an exact algebraic type. It is used to define points with algebraic coordinates. Typically we use one of the standard CGAL kernels, instantiated with the number type `NtTraits::Algebraic` (see below).
- The `NtTraits` class (the number-type traits class) encapsulates all the numeric operations needed for performing the geometric computation carried out by the geometric traits class. It defines the *Integer*, *Rational* and *Algebraic* number-types, and supports several operations on these types, such as conversion between number types, solving quadratic equations and extracting the real roots of a polynomial with integer coefficients. It is highly recommended to use the `CORE_algebraic_number_traits` class, which is included in the arrangement package. It relies on the exact number types implemented in the CORE library and performs exact computations on the number types it defines.

¹³Namely, they are roots of polynomials with integer coefficients of degree 4. However, in some special cases, for example when handling only circles and circular arcs, the coordinates of the intersection points are only of degree 2, namely they are solutions of quadratic equations.

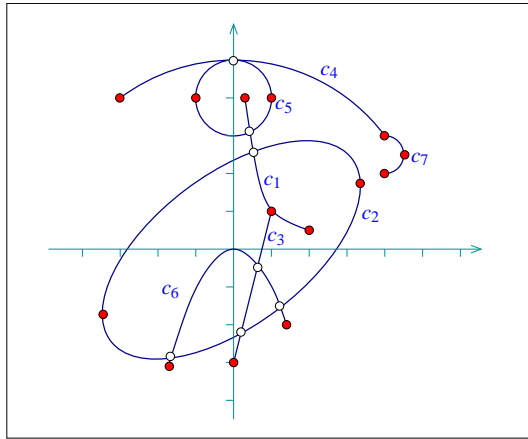

Figure 30.15: An arrangement of mixed conic arcs, as constructed in *conics.cpp*.

The *Arr_conic_traits_2* models the *ArrangementTraits_2* and the *ArrangementLandmarkTraits_2* concepts. (It supports the landmark point-location strategy). Its *Point_2* type is derived from *AlgKernel::Point_2*, while the *Curve_2* type represents a bounded, not necessarily *x*-monotone, conic arc. The *X_monotone_curve_2* type is derived from *Curve_2*, but its constructors are to be used only by the traits class. You should therefore construct only *Curve_2* objects and insert them into the arrangement using the *insert()* or *insert()* functions.

Conic arcs can be constructed from full ellipses or by specifying a supporting curve, two endpoints and an orientation. However, several constructors of *Curve_2* are available to allow for some special cases, such as circular arcs or line segments. The *Curve_2* (and the derived *X_monotone_curve_2*) classes also support basic access functions such as *source()*, *target()* and *orientation()*.

Examples for Arrangements of Conics

The following example demonstrates the usage of the various constructors for conic arcs. The resulting arrangement is depicted in Figure 30.15. Especially noteworthy are the constructor of a circular arc that accepts three points and the constructor that allows specifying approximate endpoints, where the exact endpoints are given explicitly as intersections of the supporting conic with two other conic curves. Also note that as the preconditions required by some of these constructors are rather complicated (see the Reference Manual for the details), a precondition violation does not cause the program to terminate — instead, an *invalid* arc is created. We can verify the validity of an arc by using the *is_valid()* method. Needless to say, inserting invalid arcs into an arrangement is not allowed.

File: examples/Arrangement_on_surface_2/conics.cpp

The last example in this section demonstrates how the conic-traits class can handle intersection points with multiplicity. The supporting curves of the two arcs, a circle centered at $(0, \frac{1}{2})$ with radius $\frac{1}{2}$, and the hyperbola

$y = \frac{x^2}{1-x}$,¹⁴ intersect at the origin such that the intersection point has multiplicity 3 (note that they both have the same horizontal tangent at $(0,0)$ and the same curvature 1). In addition, they have another intersection point at $(\frac{1}{2}, \frac{1}{2})$ of multiplicity 1:

```
#include <CGAL/basic.h>

#ifndef CGAL_USE_CORE

30.6.6 A Traits Class for Arcs of Rational Functions

A *rational function* is given by the equation $y = \frac{P(x)}{Q(x)}$, where P and Q are polynomials of arbitrary degrees. In particular, if $Q(x) = 1$, then the function is a simple polynomial function. A bounded *rational arc* is defined by the graph of a rational function over some interval $[x_{\min}, x_{\max}]$, where Q does not have any real roots in this interval (Thus, the arc does not contain any poles). Rational functions, and polynomial functions in particular, are not only interesting in their own right, they are also very useful for approximating or interpolating more complicated curves; see, e.g., [PTVF02, Chapter 3].

The computations with rational arcs are guaranteed to be robust and exact, assuming that the coefficient of the polynomials P and Q are rational numbers. The x -values that determine the interval over which the arc is defined can however be arbitrary algebraic numbers.

Using the `Arr_rational_arc_traits_2<AlgKernel, NtTraits>` class template it is possible to construct and maintain arrangement of rational arcs. The template parameters are very similar to the ones used by the `Arr_conic_traits_2` class template; see the previous section. However, no rational kernel is needed. Also in this case it is recommended to use the `CORE_algebraic_number_traits` class, with a kernel instantiated with the *Algebraic* type defined by this class.

The `Arr_rational_arc_traits_2` is a model of the `ArrangementTraits_2` concept (but not of the `ArrangementLandmarkTraits_2` concept, so it is not possible to use the landmark point-location strategy for arrangements of rational arcs). Its `Point_2` type is derived from `AlgKernel::Point_2`, while the `Curve_2` and `X_monotone_curve_2` types refer to the same class (note that a rational arc is always x -monotone). The traits class also defines the `Rat_vector` type, representing a vector of rational coefficients, (whose type is `NtTraits::Rational`). A rational arc can be constructed from a single vector of coefficients, specifying the polynomial P alone (and $Q(x) = 1$), or from two vectors of coefficients, specifying both P and Q .

The following example demonstrates the construction of an arrangement of rational arcs depicted in Figure 30.16. Note the usage of the two constructors, for polynomial arcs and for rational arcs:

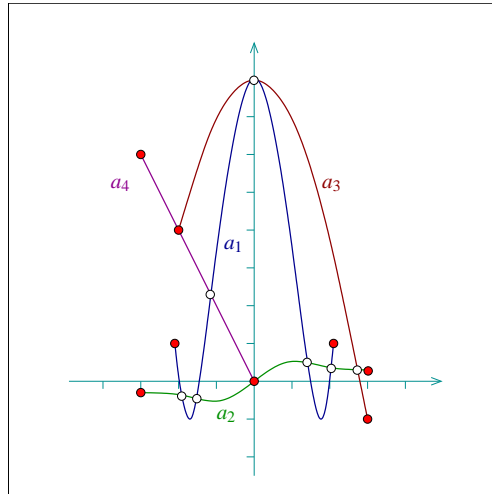

Figure 30.16: An arrangement of four arcs of rational functions, as constructed in *rational_functions.cpp*.

return 0;
}
#endif

```

File: examples/Arrangement_on_surface_2/rational_functions.cpp

The following example demonstrates the construction of an arrangement of six rational arcs — four unbounded arcs and two bounded ones — as depicted in Figure 30.10. Note the usage of the constructors of an entire rational

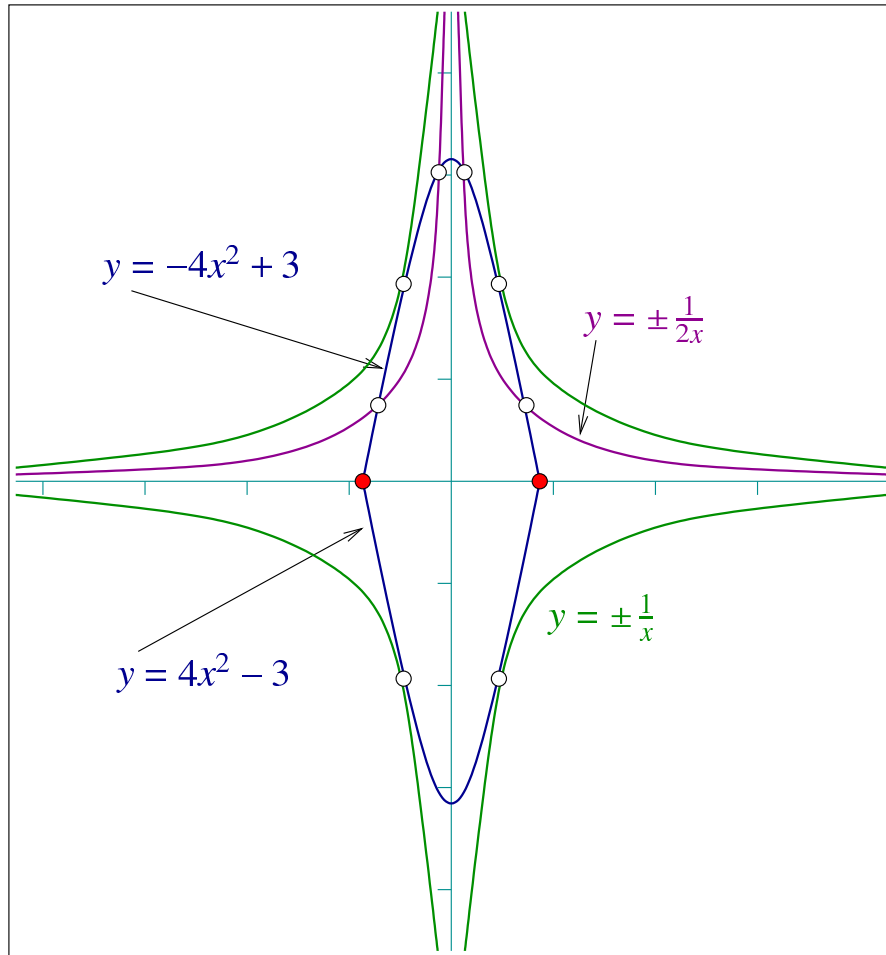

Figure 30.17: An arrangement of six arcs of rational functions, as constructed in *unbounded_rational_functions.cpp*.

function and of an infinite “ray” of such a function. Also observe that the hyperbolas $y = \pm \frac{1}{x}$ and $y = \pm \frac{1}{2x}$ never intersect, although they have common vertical and horizontal asymptotes, so very “thin” unbounded faces are created between them:

```
#include <CGAL/basic.h>

#ifdef CGAL_USE_CORE
#include <iostream>
int main ()
{
    std::cout << "Sorry, this example needs CORE ..." << std::endl;
    return (0);
}
#else

#include <CGAL/Cartesian.h>

30.6.7 A Traits Class for Planar Bézier Curves

A planar *Bézier curve* B is a parametric curve defined by a sequence of *control points* p_0, \dots, p_n as follows:

$$B(t) = (X(t), Y(t)) = \sum_{k=0}^n p_k \cdot \frac{n!}{k!(n-k)!} \cdot t^k (1-t)^{n-k}.$$

where $t \in [0, 1]$. The degree of the curve is therefore n — namely, $X(t)$ and $Y(t)$ are polynomials of degree n . Bézier curves have numerous applications in computer graphics and solid modelling. They are used, for example, in free-form sketches and for defining the true-type fonts.

Using the `Arr_Bezier_curve_traits_2<RatKernel, AlgKernel, NtTraits>` class template it is possible to construct and maintain arrangements of Bézier curves that are given by rational control points (a sequence of objects of the `RatKernel::Point_2` type). We can handle curves of arbitrary degree (in general, a sequence of $n + 1$ control points define a Bézier curve of degree n). The template parameters are the same ones used by the `Arr_conic_traits_2` class template, and here it is also recommended to use the `CORE_algebraic_number_traits` class, with Cartesian kernels instantiated with the *Rational* and *Algebraic* number-types defined by this class.

As mentioned above, we assume that the coordinates of all control points that define a Bézier curve are rational numbers, so both $X(t)$ and $Y(t)$ are polynomials with rational coefficients. The intersection points between curves are however algebraic numbers, and their exact computation is time-consuming. The traits class therefore contains a layer of geometric filtering that performs all computation in an approximate manner whenever possible. Thus, it resorts to exact computations only when the approximate computation fails to produce an unambiguous result. Note that most arrangement vertices are therefore associated with approximated points. You cannot access the coordinates of such points and obtain them as algebraic numbers, and only access to the approximate coordinates is possible. See the Reference Manual for the exact interface of the `Point_2`, `Curve_2` and `X_monotone_curve_2` defined by the traits class.

The `Arr_Bezier_curve_traits_2` is a model of the `ArrangementTraits_2` concept (but not of the `ArrangementLandmarkTraits_2` concept, so it is not possible to use the landmark point-location strategy for arrangements of rational arcs).

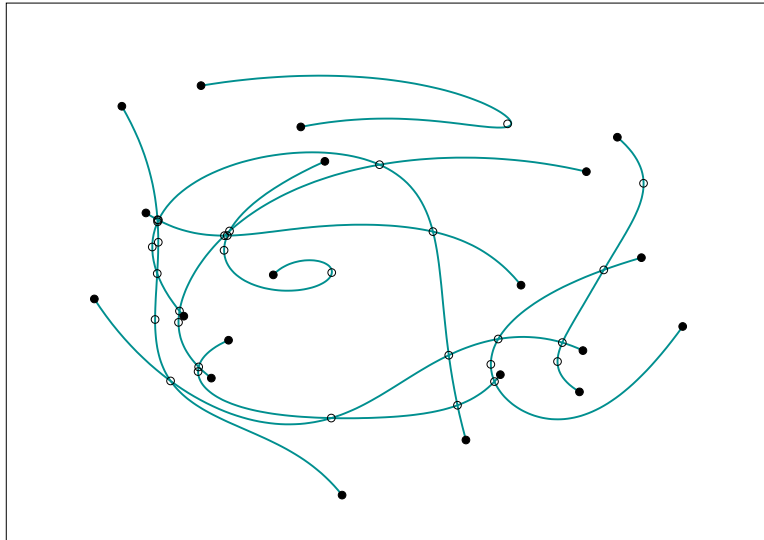

Figure 30.18: An arrangement of ten Bézier curves of degree 5, as constructed in *Bezier_curves.cpp*.

The following example reads a set of Bézier curves from an input file, where each file is specified by an integer stating its number of control points, followed by the sequence of control points, given in integer or rational coordinates. By default, the program uses the *Bezier.dat* file, which contains ten curves of degree 5 each; their resulting arrangement is depicted in Figure 30.18.

```

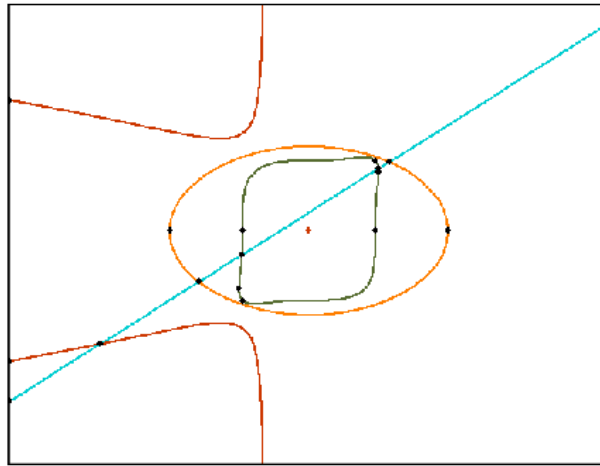

Figure 30.19: An arrangement of algebraic curves of degrees 1, 2, 3, and 6, as constructed in *algebraic_curves.cpp*.

30.6.8 A Traits Class for Planar Algebraic Curves of Arbitrary Degree

An algebraic curve C in the plane is defined as the (real) zero locus of a polynomial $f(x,y)$ in two variables. The curve is uniquely defined by f (although several polynomials might define the same curve). We call f a *defining polynomial* of C .

We consider arrangements induced by algebraic curves or by (weakly) x -monotone segments for algebraic curves (Such a segment is not necessarily the maximal possible (weakly) x -monotone segment; see below.) When talking about algebraic curves, we use the term “segment” for a continuous, possibly non-linear subset of an algebraic curve – see the definition below. There are no restrictions on the algebraic curve, that means, we support unbounded curves, vertical curves or segments, and isolated points.

The `Arr_algebraic_segment_traits_2<Coefficient>` class template is a model of the `ArrangementTraits_2` concept (but not of the `ArrangementLandmarkTraits_2` concept, so it is not possible to use the landmark point-location strategy for arrangements of algebraic curves). The template argument *Coefficient* determines the type of the scalar coefficients of the polynomial. Currently supported types are `leda_integer`, `CORE::BigInt`, and any instance of `CGAL::Sqrt_extension<A,B>` instantiated with one of the integral types above.

The traits class defines a type `Curve_2` for algebraic curves. Such a type can be constructed by the `Construct_curve_2` functor, which accepts an instance of `Polynomial_2` as an argument. This polynomial type is also available by the traits class and constitutes a valid model of the concept `Polynomial_d` with two variables (see ??).

The following examples computes the arrangement induced by the four curves in Figure 30.19

```
#include <CGAL/basic.h>
#include <iostream>

#if (!CGAL_USE_CORE) && (!CGAL_USE_LEDA) && (!(CGAL_USE_GMP &&
    CGAL_USE_MPFI))
int main ()
{
    std::cout << "Sorry, this example needs CORE, LEDA, or GMP+MPFI ..."
              << std::endl;
    return 0;
}
```

```

File: examples/Arrangement_on_surface_2/algebraic_curves.cpp

We first give a precise definition of segments of algebraic curves. A point p on a curve $C_f \subset \mathbb{R}^2$ (with f its defining equation) is called *semi-regular*, if locally around p , C_f can be written as a function graph of some continuous function in x or in y (we also say that p is parameterizable in x or y , respectively). The only two cases of non-semi-regular points are isolated points, and self-intersections. A *segment* of a curve is a closed and continuous point set such that each interior point is semi-regular. It follows that a weakly x -monotone segment is either a completely vertical segment, or a segment whose interior points are all parameterizable in x .

The traits class allows to construct weakly x -monotone segments of a curve using the *Construct_x_monotone_segment_2* functor. The *X_monotone_curve_2* type of the traits class represents weakly x -monotone segments of a curve; however, segments may need to be further subdivided into several (sub-)segments, for technical reasons. Therefore, *Construct_x_monotone_segment_2* constructs a sequence of *X_monotone_curve_2* objects, whose union represents the weakly x -monotone segment that was queried. We call a segment *terminal* if it can be represented by the type *X_monotone_curve_2*.

— advanced —

The subdivision of segments is due to the internal representation of x -monotone segments, which is based on a vertical decomposition. We assume the defining polynomial f of the curve C to be *square-free*, that means, it contains no divisor g^2 of total degree greater than zero. We define a (complex) *critical point* $p \in \mathbb{C}^2$ by

$$f(p) = 0 = \frac{\partial f}{\partial y}(p).$$

An x -coordinate $\alpha \in \mathbb{R}$ is *critical* if either some critical point has x -coordinate α , or if the leading coefficient of f , considered as a polynomial in y , vanishes. In particular, vertical lines of and isolated point of C can only take place at critical x -coordinates. Between two consecutive critical x -coordinates, the curve decomposes into

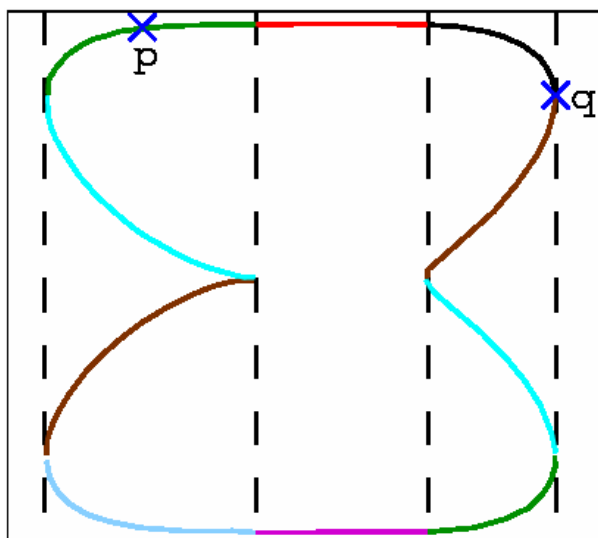

Figure 30.20: The critical x -coordinates of an algebraic curve (dashed lines), and its decomposition into terminal segments (in different colors). The segment from p to q consists of the union of three terminal segments.

a finite number of x -monotone segments (the same is true on the left of the leftmost, and on the right of the rightmost critical x -coordinate). The type *X_monotone_curve_2* is only able to represent such segments (and sub-segments of them). See Figure 30.20 for an example of a decomposition into terminal segments. Formally, a terminal segment is a weakly x -monotone segment that is either vertical, or its x -range contains no critical point in its interior.

— advanced —

Coordinates of points are represented by the type *Algebraic_real_1*, which is defined in the traits class. This type is taken from a model of the *AlgebraicKernel_1* concept, which is also available by the type *Algebraic_kernel_1*. One can use this model to create algebraic numbers as roots of univariate polynomials, and process them, for instance, compare them, or approximate them to any precision. See the documentation of *AlgebraicKernel_1* for more information. One can construct an object of type *Point_2* by a triple (x_0, cv, i) , which means that the i -th point (counted from below) in the fiber of cv at the x -coordinate x_0 is constructed. This is also how points are presented internally. In the example displayed in Figure 30.20, if x_1 denotes the x -coordinate of p , and cv represents the algebraic curve, then p could be represented by $(x_1, cv, 3)$. If x_2 is the x -coordinate of q , then $(x_2, cv, 1)$ is a valid representation of q . Although the y -coordinate of an object of type *Point_2* can be queried, we recommend to be careful with that option, since computing an explicit representation of the y -coordinate as an *Algebraic_real_1* object can become rather expensive.

The following code exemplifies various methods to construct algebraic segments. The computed arrangement is displayed in Figure 30.21.

```
#include <CGAL/basic.h>
#include <iostream>

#if (!CGAL_USE_CORE) && (!CGAL_USE_LEDA) && (! (CGAL_USE_GMP &&
    CGAL_USE_MPF1))
int main ()
{
    std::cout << "Sorry, this example needs CORE, LEDA, or GMP+MPFI ..."
        << std::endl;
    return 0;
}
```

30.6.9 Traits-Class Decorators

Geometric traits-class decorators allow you to attach auxiliary data to curves and to points. The data is automatically manipulated by the decorators and distributed to the constructed geometric entities. Note that additional information can alternatively be maintained by extending the vertex, halfedge, or face types provided by the DCEL class used by the arrangement; see the details in [Section 30.8](#).

The arrangement package includes a generic traits-class decorator template named *Arr_curve_data_traits_2*<*BaseTraits*, *XMonotoneCurveData*, *Merge*, *CurveData*, *Convert*>. This decorator is used to attach a data field to curves and to *x*-monotone curves. It is parameterized by a base-traits class, which is one of the geometric traits classes described in the previous subsections, or a user-defined traits class. The curve-data decorator derives itself from the base-traits class, and in particular inherits its *Point_2* type. In addition:

- *Curve_2* is derived from the basic *BaseTraits::Curve_2* class, extending it by an extra field of type *CurveData*.
- *X_monotone_curve_2* is derived from the basic *BaseTraits::X_monotone_curve_2* class, extending it by an extra field of type *XMonotoneCurveData*.

Note that the *Curve_2* and *X_monotone_curve_2* are not the same, even if the *BaseTraits::Curve_2* and *BaseTraits::X_monotone_curve_2* are (as in the case of the segment-traits class for example). The extended curve types support the additional methods *data()* and *set_data()* for accessing and modifying the data field.

You can create an extended curve (or an extended x-monotone curve) from a basic curve and a curve-data object. When curves are inserted into an arrangement, they may be split, and the decorator handles their data fields automatically:

- When a curve is subdivided into x-monotone subcurves, its data field of type *CurveData* is converted to an *XMonotoneCurveData* object *d* using the *Convert* functor. The object *d* is automatically associated with each of the resulting x-monotone subcurves.

Note that by default, the *CurveData* type is identical to the *XMonotoneCurveData* type (and the conversion functor *Convert* is trivially defined). Thus, the data field associated with the original curve is just duplicated and stored with the x-monotone subcurves.

- When an x-monotone curve is split into two, the decorator class automatically copies its data field to both resulting subcurves.
- When intersecting two x-monotone curves c_1 and c_2 , the result may include overlapping sections, represented as x-monotone curves. In this case the data fields of c_1 and c_2 are merged into a single *XMonotoneCurveData* object, using the *Merge* functor, which is supplied as a parameter to the traits class-template. The resulting object is assigned to the data field of the overlapping subcurves.
- Merging two x-monotone curves is allowed only when (i) the two curves are geometrically mergeable — that is, the base-traits class allows to merge them — and (ii) the two curves store the same data field.

The *Arr_consolidated_curve_data_traits_2*<*BaseTraits*, *Data*> decorator specializes the generic curve-data decorator. It extends the basic *BaseTraits::Curve_2* by a single *Data* field, and the basic *BaseTraits::X_monotone_curve_2* with a *set* of (distinct) data objects. The *Data* type is required to support the equality operator, used to ensure that each set contains only distinct data objects with no duplicates. When a curve with a data field *d* is subdivided into x-monotone subcurves, each subcurve is associated with a set $S = \{d\}$. In case of an overlap between two x-monotone curves c_1 and c_2 with associated data sets S_1 and S_2 , respectively, the overlapping subcurve is associated with the consolidated set $S_1 \cup S_2$.

Examples

In the following example, we use *Arr_segment_traits_2* as our base-traits class, attaching an additional *color* field to the segments using the consolidated curve-data traits class. A color may be either *blue* or *red*. Having constructed the arrangement of colored segments, as depicted in Figure 30.22, we detect the vertices that have incident edges mapped to both blue and red segments. Thus, they correspond to red–blue intersection points. We also locate the edge that corresponds to overlaps between red and blue line segments:

```
#include "arr_rational_nt.h"
#include <CGAL/Cartesian.h>
#include <CGAL/Arr_segment_traits_2.h>
#include <CGAL/Arr_consolidated_curve_data_traits_2.h>
```

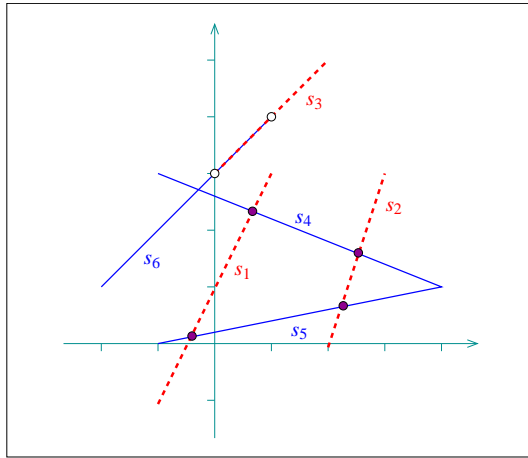

Figure 30.22: An arrangement of six red and blue segments, as constructed in *consolidated_curve_data.cpp*. Disks correspond to red–blue intersection points, while circles mark the endpoints of red–blue overlaps.

```
#include <CGAL/Arrangement_2.h>
#include <CGAL/Arr_landmarks_point_location.h>

enum Segment_color {
    RED,
    BLUE
};

typedef CGAL::Cartesian<Number_type>           Kernel;
typedef CGAL::Arr_segment_traits_2<Kernel>      Segment_traits_2;

std::endl;
}
return 0;
}

```

File: examples/Arrangement_on_surface_2/consolidated_curve_data.cpp

In the following example, we use *Arr_polyline_traits_2* as our base-traits class, attaching an additional *name* field to each polyline using the generic curve-data traits class. In case of overlaps, we simply concatenate the names of the overlapping polylines. Also notice how we replace the curve associated with the edges that correspond to overlapping polylines with geometrically equivalent curves, but with a different data fields:

```

#include "arr_rational_nt.h"
#include <CGAL/Cartesian.h>
#include <CGAL/Arr_segment_traits_2.h>
#include <CGAL/Arr_polyline_traits_2.h>
#include <CGAL/Arr_curve_data_traits_2.h>
#include <CGAL/Arrangement_2.h>
#include <string>

// Define a functor for concatenating name fields.
typedef std::string Name;

struct Merge_names
{
    Name operator() (const Name& s1, const Name& s2) const
    {
        return (s1 + " " + s2);
    }
};

typedef CGAL::Cartesian<Number_type> Kernel;
typedef CGAL::Arr_segment_traits_2<Kernel> Segment_traits_2;
typedef CGAL::Arr_polyline_traits_2<Segment_traits_2> Polyline_traits_2;
typedef Polyline_traits_2::Curve_2 Polyline_2;
typedef CGAL::Arr_curve_data_traits_2<Polyline_traits_2, Name, Merge_names> Traits_2;
typedef Traits_2::Point_2 Point_2;
typedef Traits_2::Curve_2 Curve_2;
typedef Traits_2::X_monotone_curve_2 X_monotone_curve_2;
typedef CGAL::Arrangement_2<Traits_2> Arrangement_2;

int main ()
{
    // Construct an arrangement of four polylines named A--D.
    Arrangement_2 arr;

    Point_2 points1[5] = {Point_2(0,0), Point_2(2,4),
        Point_2(3,3),
        Point_2(4,4), Point_2(6,0)};
    insert (arr, Curve_2 (Polyline_2 (points1, points1 + 5), "A"));

    Point_2 points2[3] = {Point_2(1,5), Point_2(3,3),
        Point_2(5,5)};
    insert (arr, Curve_2 (Polyline_2 (points2, points2 + 3), "B"));

    Point_2 points3[4] = {Point_2(1,0), Point_2(2,2),
        Point_2(4,2), Point_2(5,0)};
    insert (arr, Curve_2 (Polyline_2 (points3, points3 + 4), "C"));

    Point_2 points4[2] = {Point_2(0,2), Point_2(6,2)};
    insert (arr, Curve_2 (Polyline_2 (points4, points4 + 2), "D"));
}

```

```

// Print all edges that correspond to an overlapping polyline.
Arrangement_2::Edge_iterator   eit;

for (eit = arr.edges_begin(); eit != arr.edges_end(); ++eit) {
    if (eit->curve().data().length() > 1) {
        std::cout << "[" << eit->curve() << "]"  "
                    << "named: " << eit->curve().data() << std::endl;

        // Rename the curve associated with the edge.
        arr.modify_edge (eit, X_monotone_curve_2 (eit->curve(),
            "overlap"));
    }
}
return 0;
}

```

File: examples/Arrangement_on_surface_2/generic_curve_data.cpp

The third example we give in this section is based on *dual_lines.cpp* given in Section 30.5.2. It constructs the arrangement of the dual lines for a set of point given in an input file (by default we use *coll_points.dat*, which contains 50 points randomly selected on the grid $[-100, 100] \times [-100, 100]$; the file contains two distinct triplets of collinear points). Here we use the generic curve-data decorator to attach the index of the primal point to each of the lines. Doing so, we can go over the incident edges of each vertex whose degree is greater than 4 and report the subsets collinear points (if we have a vertex of degree d , we actually need to go over $\frac{d}{2}$ edges, as each incident line contributes exactly 2 edges). Note that in this case the dual line cannot overlap, so we use a dummy merge functor to instantiate the curve-data traits:

```

#include "arr_rational_nt.h"
#include <CGAL/Cartesian.h>
#include <CGAL/Arr_linear_traits_2.h>
#include <CGAL/Arr_curve_data_traits_2.h>
#include <CGAL/Arrangement_2.h>

typedef CGAL::Cartesian<Number_type>           Kernel;
typedef CGAL::Arr_linear_traits_2<Kernel>      Linear_traits_2;
typedef Linear_traits_2::Point_2               Point_2;
typedef Linear_traits_2::Line_2                Line_2;
typedef CGAL::Arr_curve_data_traits_2<Linear_traits_2,
                                         unsigned int> Traits_2;
typedef Traits_2::X_monotone_curve_2          X_monotone_curve_2;
typedef CGAL::Arrangement_2<Traits_2>         Arrangement_2;

int main (int argc, char *argv[])
{
    // Get the name of the input file from the command line, or use the
    // default
    // points.dat file if no command-line parameters are given.
    const char * filename = (argc > 1) ? argv[1] : "coll_points.dat";

    // Open the input file.
    std::ifstream   in_file (filename);

```

```

if (! in_file.is_open()) {
    std::cerr << "Failed to open " << filename << " ..." << std::endl;
    return (1);
}

// Read the points from the file, and consturct their dual lines.
std::vector<Point_2>          points;
std::list<X_monotone_curve_2> dual_lines;

unsigned int n;
in_file >> n;
points.resize (n);
unsigned int k;
for (k = 0; k < n; ++k) {
    int px, py;
    in_file >> px >> py;
    points[k] = Point_2 (px, py);

    // The line dual to the point (p_x, p_y) is y = p_x*x - p_y,
    // or: p_x*x - y - p_y = 0:
    Line_2 dual_line = Line_2(Number_type(px),
                               Number_type(-1),
                               Number_type(-py));

    // Generate the x-monotone curve based on the line and the point
    // index.
    dual_lines.push_back (X_monotone_curve_2 (dual_line, k));
}
in_file.close();

// Construct the dual arrangement by aggragately inserting the lines.
Arrangement_2      arr;

insert (arr, dual_lines.begin(), dual_lines.end());

// Look for vertices whose degree is greater than 4.
Arrangement_2::Vertex_const_iterator      vit;
Arrangement_2::Halfedge_around_vertex_const_circulator  circ;
unsigned int      d;

for (vit = arr.vertices_begin(); vit != arr.vertices_end(); ++vit) {
    if (vit->degree() > 4) {
        // There should be vit->degree()/2 lines intersecting at the
        // current
        // vertex. We print their primal points and their indices.
        circ = vit->incident_halfedges();
        for (d = 0; d < vit->degree() / 2; d++) {
            k = circ->curve().data(); // The index of the primal point.
            std::cout << "Point no. " << k+1 << ": (" << points[k] << "), ";
            ++circ;
        }
        std::cout << "are collinear." << std::endl;
    }
}

```

```

    }
    return 0;
}

```

30.7 The Notification Mechanism

For some applications it is essential to know exactly what happens inside a specific arrangement-instance. For example, when a new curve is inserted into an arrangement, it might be desired to keep track of the faces that are split due to this insertion operation. Other important examples are the point-location strategies that require auxiliary data-structures (see Section 30.3.1), which must be notified on various local changes in the arrangement, in order to keep their data structures up-to-date. The arrangement package offers a mechanism that uses *observers* (see [GHJV95]) that can be attached to an arrangement instance and receive notifications about the changes this arrangement goes through.

The `Arr_observer<Arrangement>` class-template is parameterized with an arrangement class. It stores a pointer to an arrangement object, and is capable of receiving notifications *just before* a structural change occurs in the arrangement and *immediately after* such a change takes place. `Arr_observer` serves as a base class for other observer classes and defines a set of virtual notification functions, with default empty implementations.

The set of functions can be divided into three categories, as follows:

1. Notifiers of changes that affect the entire topological structure of the arrangement. This category consists of two pairs that notify the observer of the following changes:
 - The arrangement is cleared.
 - The arrangement is assigned with the contents of another arrangement.
2. Pairs of notifiers of a local change that occurs in the topological structure. Most notifier functions belong to this category. The relevant local changes include:
 - A new vertex is constructed and associated with a point.
 - An edge¹⁵ is constructed and associated with an x -monotone curve.
 - An edge is split into two edges.
 - An existing face is split into two faces, as a consequence of the insertion of a new edge.
 - A hole is created in the interior of a face.
 - Two holes are merged to form a single hole, as a consequence of the insertion of a new edge.
 - A hole is moved from one face to another, as a consequence of a face split.
 - Two edges are merged into one edge.
 - Two faces are merged into one face, as a consequence of the removal of an edge that used to separate them.
 - One hole is split into two, as a consequence of the deletion of an edge that used to connect the two components.
 - A vertex is removed.
 - An edge is removed.

¹⁵The term “edge” refers here to a pair of twin half-edges.

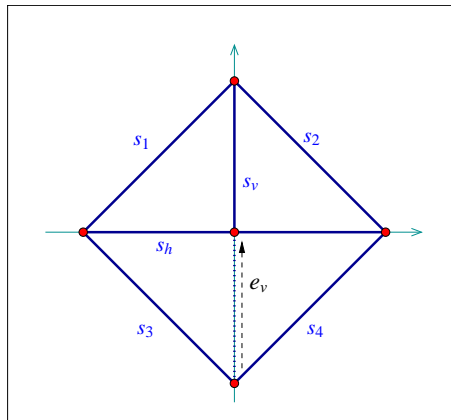

Figure 30.24: An arrangement of five line segments, as constructed in *observer.cpp*. The halfedge e_v (dashed) is eventually removed, so that the final arrangement consists of four faces (one unbounded and three bounded ones).

- A hole is deleted from the interior of a face.
3. Notifiers about a change applied by a free (global) function. This category consists of a single pair of notifiers, namely *before_global_change()* and *after_global_change()*. Neither of these functions is invoked by methods of the *Arrangement_2* class. Instead, they are called by the free functions themselves. It is implied that no point-location queries (or any other queries for that matter) are issued between the calls to the notification functions above.

See the Reference Manual for a detailed specification of the *Arr_observer* class along with the exact prototypes of all notification functions.

Each arrangement object stores a (possibly empty) list of pointers to *Arr_observer* objects, and whenever one of the structural changes listed in the first two categories above is about to take place, the arrangement object performs a *forward* traversal on this list and invokes the appropriate function of each observer. After the change takes place the observer list is traversed in a *backward* manner (from tail to head), and the appropriate notification function is invoked for each observer. This allows the nesting of observer objects.

Concrete arrangement-observer classes should inherit from *Arr_observer*. When an observer is constructed, it is attached to a valid arrangement supplied to the observed constructor, or alternatively the observer can be attached to the arrangement at a later time. When this happens, the observer instance inserts itself into the observer list of the associated arrangement and starts receiving notifications whenever this arrangement changes thereafter. Naturally, the observer object unregisters itself by removing itself from this list just before it is destroyed.

The trapezoidal RIC and the landmark point-location strategies both use observers to keep their auxiliary data structures up-to-date. Besides them, users can define their own observer classes, by inheriting from the base observer class and overriding the relevant notification functions, as required by their applications.

The following example shows how to define and use an observer class. The observer in the example keeps track of the arrangement faces, and prints a message whenever a face is split into two due to the insertion of an edge, and whenever two faces merge into one due to the removal of an edge. The layout of the arrangement is depicted in Figure 30.24:

```
#include <CGAL/Cartesian.h>
#include <CGAL/Quotient.h>
```

```

#include <CGAL/MP_Float.h>
#include <CGAL/Arr_segment_traits_2.h>
#include <CGAL/Arrangement_2.h>
#include <CGAL/Arr_observer.h>

typedef CGAL::Quotient<CGAL::MP_Float>          Number_type;
typedef CGAL::Cartesian<Number_type>            Kernel;
typedef CGAL::Arr_segment_traits_2<Kernel>      Traits_2;
typedef Traits_2::Point_2                      Point_2;
typedef Traits_2::X_monotone_curve_2           Segment_2;
typedef CGAL::Arrangement_2<Traits_2>          Arrangement_2;

// An arrangement observer, used to receive notifications of face splits
// and
// face mergers.
class My_observer : public CGAL::Arr_observer<Arrangement_2>
{
public:

    My_observer (Arrangement_2& arr) :
        CGAL::Arr_observer<Arrangement_2> (arr)
    {}

    virtual void before_split_face (Face_handle,
                                    Halfedge_handle e)
    {
        std::cout << "-> The insertion of : [ " << e->curve()
                    << " ] causes a face to split." << std::endl;
    }

    virtual void before_merge_face (Face_handle,
                                    Face_handle,
                                    Halfedge_handle e)
    {
        std::cout << "-> The removal of : [ " << e->curve()
                    << " ] causes two faces to merge." << std::endl;
    }
};

int main ()
{

    << "    V = " << arr.number_of_vertices()
    << ",    E = " << arr.number_of_edges()
    << ",    F = " << arr.number_of_faces() << std::endl;

return 0;
}

```

File: examples/Arrangement_on_surface_2/observer.cpp

Observers are especially useful when the DCEL records are extended and store additional data, as they help updating this data on-line. See Section [30.8](#) for more details and examples.

30.8 Extending the DCEL

For many applications of the arrangement package it is necessary to store additional information (perhaps of non-geometric nature) with the arrangement cells. As vertices are associated with *Point_2* objects and edges (halfedge pairs) are associated with *X_monotone_curve_2* objects, both defined by the traits class, it is possible to extend the traits-class type by using a traits-class decorator, as explained in Section [30.6.9](#), which may be a sufficient solution for some applications. However, the DCEL faces are not associated with any geometric object, so it is impossible to extend them using a traits-class decorator. Extending the DCEL face records comes handy in such cases. As a matter of fact, it is possible to conveniently extend all DCEL records (namely vertices, halfedges and faces), which can also be advantageous for some applications.

All examples presented so far use the default *Arr_default_dcel<Traits>*. This is done implicitly, as this class serves as a default parameter for the *Arrangement_2* template. The default DCEL class just associates points with vertices and *x*-monotone curves with halfedge, but nothing more. In this section we show how to use alternative DCEL types to extend the desired DCEL records.

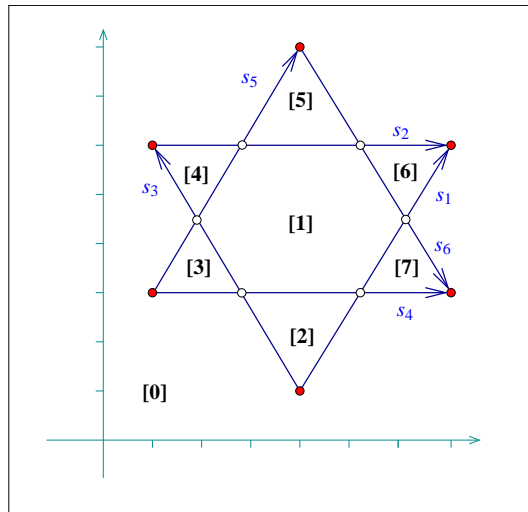

Figure 30.25: An arrangement of six line segments, as constructed in *face_extension.cpp* and *dcel_extension.cpp* (in *dcel_extension.cpp* we treat the segments as directed, so they are drawn as arrows directed from the source to the target). The indices associated with the halfedges in *face_extension.cpp* are shown in brackets.

30.8.1 Extending the DCEL Faces

The *Arr_face_extended_dcel*<Traits, FaceData> class-template is used to associate auxiliary data field of type *FaceData* to each face record in the DCEL.

When an *Arrangement_2* object is parameterized by this DCEL class, its nested *Face* type is extended with the access function *data()* and with the modifier *set_data()*. Using these extra functions it is straightforward to access and maintain the auxiliary face-data field.

Note that the extra data fields must be maintained by the application programmers. They may choose to construct their arrangement, and only then go over the faces and attach the appropriate data fields to the arrangement faces. However, in some cases the face data can only be computed when the face is created (split from another face, or merged with another face). In such cases one can use an arrangement observer tailored for this task, which receives updates whenever a face is modified and sets its data field accordingly.

The next example constructs an arrangement that contains seven bounded faces induced by six line segments (see Figure 30.25). An observer gets notified each time a new face *f* is created and it associates *f* with a running index, (where the index of the unbounded face is 0). As a result, the faces are numbered according to their creation order, as one can easily verify by examining the insertion order of the segments:¹⁶

```
#include "arr_rational_nt.h"
#include <CGAL/Cartesian.h>
#include <CGAL/Arr_segment_traits_2.h>
#include <CGAL/Arrangement_2.h>
#include <CGAL/Arr_extended_dcel.h>
#include <CGAL/Arr_observer.h>

typedef CGAL::Cartesian<Number_type>           Kernel;
typedef CGAL::Arr_segment_traits_2<Kernel>      Traits_2;
```

¹⁶For simplicity, the particular observer used must be attached to an empty arrangement. It is not difficult however to modify the program to handle the general case of attaching a similar observer to a non-empty arrangement.

```

typedef Traits_2::Point_2                Point_2;
typedef Traits_2::X_monotone_curve_2    Segment_2;
typedef CGAL::Arr_face_extended_dcel<Traits_2, int> Dcel;
typedef CGAL::Arrangement_2<Traits_2, Dcel> Arrangement_2;

// An arrangement observer, used to receive notifications of face splits
// and
// to update the indices of the newly created faces.
class Face_index_observer : public CGAL::Arr_observer<Arrangement_2>
{
private:
    int      n_faces;          // The current number of faces.

public:

    Face_index_observer (Arrangement_2& arr) :
        CGAL::Arr_observer<Arrangement_2> (arr),
        n_faces (0)
    {
        CGAL_precondition (arr.is_empty());

        arr.unbounded_face()->set_data (0);
        n_faces++;
    }

    virtual void after_split_face (Face_handle /* old_face */,
                                   Face_handle new_face, bool )
    {
        // Assign index to the new face.
        new_face->set_data (n_faces);
        n_faces++;
    }
};

        do {
            std::cout << " --> " << curr->target()->point();
            ++curr;
        } while (curr != fit->outer_ccb());
        std::cout << std::endl;
    }
}

return 0;
}

```

File: examples/Arrangement_on_surface_2/face_extension.cpp

30.8.2 Extending All DCEL Records

The `Arr_extended_dcel<Traits, VertexData, HalfedgeData, FaceData>` class-template is used to associate auxiliary data fields of types `VertexData`, `HalfedgeData`, and `FaceData` to each DCEL vertex, halfedge, and face record types, respectively.

When an `Arrangement_2` object is injected with this DCEL class, each one of its nested `Vertex`, `Halfedge` and `Face` classes is extended by the access function `data()` and by the modifier `set_data()`.

The next example shows how to use a DCEL with extended vertex, halfedge, and face records. In this example each vertex is associated with a color, which may be blue, red, or white, depending on whether the vertex is isolated, represents a segment endpoint, or whether it represents an intersection point. Each halfedge is associated with Boolean flag indicating whether its direction is the same as the direction of its associated segment (in this example segments are treated as directed objects). Each face is also extended to store the size of its outer boundary.

The constructed arrangement, depicted in Figure 30.25, is similar to the arrangement constructed in the previous example. Note that all auxiliary data fields are set during the construction phase. Also note that the data fields are properly maintained when the arrangement is copied to another arrangement instance:

```

#include "arr_rational_nt.h"
#include <CGAL/Cartesian.h>
#include <CGAL/Arr_segment_traits_2.h>

```

```

#include <CGAL/Arrangement_2.h>
#include <CGAL/Arr_extended_dcel.h>

enum Color {BLUE, RED, WHITE};

typedef CGAL::Cartesian<Number_type> Kernel;
typedef CGAL::Arr_segment_traits_2<Kernel> Traits_2;
typedef Traits_2::Point_2 Point_2;
typedef Traits_2::X_monotone_curve_2 Segment_2;
typedef CGAL::Arr_extended_dcel<Traits_2, Color, bool, int> Dcel;
typedef CGAL::Arrangement_2<Traits_2, Dcel> Arrangement_2;

int main ()
{
    // Construct the arrangement containing two intersecting triangles.
    Arrangement_2 arr;

    Segment_2 s1 (Point_2(4, 1), Point_2(7, 6));
    Segment_2 s2 (Point_2(1, 6), Point_2(7, 6));
    Segment_2 s3 (Point_2(4, 1), Point_2(1, 6));
    Segment_2 s4 (Point_2(1, 3), Point_2(7, 3));
    Segment_2 s5 (Point_2(1, 3), Point_2(4, 8));
    Segment_2 s6 (Point_2(4, 8), Point_2(7, 3));

    insert_non_intersecting_curve (arr, s1);
    insert_non_intersecting_curve (arr, s2);
    insert_non_intersecting_curve (arr, s3);
    insert (arr, s4);
    insert (arr, s5);
    insert (arr, s6);

    // Go over all arrangement vertices and set their colors according to
    // our
    // coloring convention.
    Arrangement_2::Vertex_iterator vit;
    unsigned int degree;

    for (vit = arr.vertices_begin(); vit != arr.vertices_end(); ++vit)
    {
        degree = vit->degree();
        if (degree == 0)
            vit->set_data (BLUE); // Isolated vertex.
        else if (degree <= 2)
            vit->set_data (RED); // Vertex represents an endpoint.
        else
            vit->set_data (WHITE); // Vertex represents an intersection
            point.
    }

    // Go over all arrangement edges and set their flags.
    Arrangement_2::Edge_iterator eit;
    bool flag;

```

```

for (eit = arr.edges_begin(); eit != arr.edges_end(); ++eit) {
    // Check if the halfedge has the same direction as its associated
    // segment. Note that its twin always has an opposite direction.
    flag = (eit->source()->point() == eit->curve().source());
    eit->set_data (flag);
    eit->twin()->set_data (!flag);
}

// For each arrangement face, print the outer boundary and its size.
Arrangement_2::Face_iterator          fit;
Arrangement_2::Ccb_halfedge_circulator curr;
int                                    boundary_size;

for (fit = arr.faces_begin(); fit != arr.faces_end(); ++fit) {
    boundary_size = 0;
    if (! fit->is_unbounded()) {
        curr = fit->outer_ccb();
        do {
            ++boundary_size;
            ++curr;
        } while (curr != fit->outer_ccb());
    }
    fit->set_data (boundary_size);
}

// Copy the arrangement and print the vertices.
Arrangement_2    arr2 = arr;

std::cout << "The arrangement vertices:" << std::endl;
for (vit = arr2.vertices_begin(); vit != arr2.vertices_end(); ++vit) {
    std::cout << '(' << vit->point() << " ) - ";
    switch (vit->data()) {
        case BLUE   : std::cout << "BLUE." << std::endl; break;
        case RED    : std::cout << "RED."  << std::endl; break;
        case WHITE  : std::cout << "WHITE." << std::endl; break;
    }
}

return 0;
}

```

— advanced —

The various DCEL classes presented in this section are perfectly sufficient for most applications based on the arrangement package. However, users may also use their own implementation of a DCEL class to instantiate the *Arrangement_2* class-template, in case they need special functionality from their DCEL. Such a class must be a model of the concept *ArrangementDcel*, whose exact specification is listed in the Reference Manual.

30.9 Overlaying Arrangements

Assume that we are given two geographic maps represented as arrangements with some data objects attached to their faces, representing some geographic information — for example, a map of the annual precipitation in some country and a map of the vegetation in the same country. It is interesting to overlay the two maps to locate, for example, the regions where there is a pine forest and the annual precipitation is between 1000 mm and 1500 mm.

Computing the overlay of two planar arrangement is also useful for supporting Boolean set operations on polygons (or generalized polygons, see, e.g., [BEH⁺02]).

The function *overlay* (*arr_a*, *arr_b*, *ovl_arr*, *ovl_traits*) accepts two input arrangement instances *arr_a* and *arr_b*, and constructs their overlay instance *ovl_arr*. All three arrangements must use the same geometric primitives. More precisely, let *arr_a* be of type *Arrangement_2*<*Traits_A*, *Dcel_A*>, *arr_b* be of type *Arrangement_2*<*Traits_B*, *Dcel_B*> and the resulting *ovl_arr* be of type *Arrangement_2*<*Traits_R*, *Dcel_R*>. All types nested in geometry traits *Traits_A*, e.g., *Point_2* and *X_monotone_curve_2*, must be convertible to the corresponding types nested in geometry traits *Traits_R*. The same holds for all types nested in geometry traits *Traits_B*. The *ovl_traits* parameter is an instance of an *overlay traits-class*, which enables the creation of *Dcel_R* records in the overlaid arrangement from the DCEL features of *arr_a* and *arr_b* that they correspond to.

In principle, we distinguish between three levels of overlay:

Simple overlay: An overlay of two arrangements that store no additional data with their DCEL records. That is, they are defined using the default DCEL class *Arr_default_dcel*. Typically, the overlaid arrangement in this case stores no extra data with its DCEL records as well (or if it does, the additional data fields cannot be computed by the overlay operation), so by overlaying the two arrangement we just compute the arrangement of all curves that induce *arr_a* and *arr_b*. Note that the same result can be obtained using the standard insertion operations, but users may choose to use overlay computation in order to achieve better running times.

The *Arr_default_overlay_traits* class should be used as an overlay traits-class for such simple overlay operations.

Face overlay: An overlay of two arrangements that store additional data fields with their faces (e.g., the geographic-map example given in the beginning of this section). The resulting overlaid arrangement typically also stores extraneous data fields with its faces, where the data field that is attached to an overlaid face can be computed from the data fields of the two faces (in *arr_a* and *arr_b*) that induce the overlaid face.

The *Arr_face_overlay_traits* class should be used as an overlay traits-class for face-overlay operations. It operates on arrangement, whose DCEL representation is based on the *Arr_face_extended_dcel* class-template (see Section 30.8.1). The face-overlay traits-class is parameterized by a functor that is capable of combining two face-data fields of types *Dcel_A::Face_data* and *Dcel_B::Face_data*, and computing the output *Dcel_R::Face_data* object. The overlay traits-class uses this functor to properly construct the overlaid faces.

Full overlay: An overlay of two arrangements that store additional data fields with all their DCEL records. That is, their DCEL classes are instantiations of the *Arr_extended_dcel* class-template (see Section 30.8.2), where the resulting arrangement also extends its DCEL records with data fields computed on the basis of the overlapping DCEL features of the two input arrangements.

In the following subsections we give some examples for the simple and the face-overlay operations and demonstrate how to use the auxiliary overlay traits-classes. For the full overlay operations users need to implement their specialized overlay traits-class, which models the *OverlayTraits* concept. The details of this concept are given in the Reference Manual.

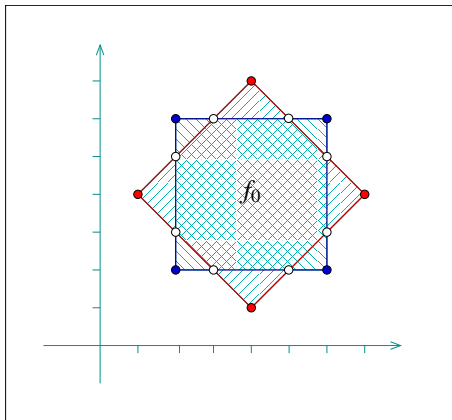

Figure 30.26: Overlaying two simple arrangements of line segments, as done in *overlay.cpp* and *ex_face_extension_overlay.cpp*. In *face_extension_overlay.cpp* the two bounded faces are considered as *marked*, and the octagonal face which is the intersection of the two marked faces is denoted by f_0 .

30.9.1 Example for a Simple Overlay

The next program constructs two simple arrangements, as depicted in Figure 30.26 and computes their overlay:

```
#include "arr_rational_nt.h"
#include <CGAL/Cartesian.h>
#include <CGAL/Arr_segment_traits_2.h>
#include <CGAL/Arrangement_2.h>
#include <CGAL/Arr_overlay_2.h>
#include <CGAL/Arr_default_overlay_traits.h>

typedef CGAL::Cartesian<Number_type>           Kernel;
typedef CGAL::Arr_segment_traits_2<Kernel>      Traits_2;
typedef Traits_2::Point_2                      Point_2;
typedef Traits_2::X_monotone_curve_2           Segment_2;
typedef CGAL::Arrangement_2<Traits_2>          Arrangement_2;
typedef CGAL::Arr_default_overlay_traits<Arrangement_2> Overlay_traits;

int main ()
{
    // Construct the first arrangement, containing a square-shaped face.
    Arrangement_2      arr1;

    Segment_2          s1 (Point_2(2, 2), Point_2(6, 2));
    Segment_2          s2 (Point_2(6, 2), Point_2(6, 6));
    Segment_2          s3 (Point_2(6, 6), Point_2(2, 6));
    Segment_2          s4 (Point_2(2, 6), Point_2(2, 2));

    insert_non_intersecting_curve (arr1, s1);
    insert_non_intersecting_curve (arr1, s2);
    insert_non_intersecting_curve (arr1, s3);
    insert_non_intersecting_curve (arr1, s4);

    // Construct the second arrangement, containing a rhombus-shaped face.
```

```

Arrangement_2      arr2;

Segment_2          t1 (Point_2(4, 1), Point_2(7, 4));
Segment_2          t2 (Point_2(7, 4), Point_2(4, 7));
Segment_2          t3 (Point_2(4, 7), Point_2(1, 4));
Segment_2          t4 (Point_2(1, 4), Point_2(4, 1));

insert_non_intersecting_curve (arr2, t1);
insert_non_intersecting_curve (arr2, t2);
insert_non_intersecting_curve (arr2, t3);
insert_non_intersecting_curve (arr2, t4);

// Compute the overlay of the two arrangements.
Arrangement_2      overlay_arr;
Overlay_traits      overlay_traits;

overlay (arr1, arr2, overlay_arr, overlay_traits);

// Print the size of the overlaid arrangement.
std::cout << "The overlaid arrangement size:" << std::endl
          << "    V = " << overlay_arr.number_of_vertices()
          << ",    E = " << overlay_arr.number_of_edges()
          << ",    F = " << overlay_arr.number_of_faces() << std::endl;

return 0;
}

```

30.9.2 Examples for a Face Overlay

The following example shows how to compute the intersection of two polygons using the *overlay()* function. It uses a face-extended DCEL class to define our arrangement class. The DCEL extends each face with a Boolean flag. A polygon is represented as a *marked* arrangement face, (whose flag is set). The example uses a face-overlay traits class, instantiated with a functor that simply performs a logical *and* operations on Boolean flags. As a result, a face in the overlaid arrangement is marked only when it corresponds to an overlapping region of two marked cells in the input arrangements. Namely, it is part of the intersection of the two polygons.

The example computes the intersection between a square and a rhombus, (which is actually also a square). The resulting polygon is an octagon, denoted by f_0 in Figure 30.26:

```

#include "arr_rational_nt.h"
#include <CGAL/Cartesian.h>
#include <CGAL/Arr_segment_traits_2.h>
#include <CGAL/Arrangement_2.h>
#include <CGAL/Arr_extended_dcel.h>
#include <CGAL/Arr_overlay_2.h>
#include <CGAL/Arr_default_overlay_traits.h>

typedef CGAL::Cartesian<Number_type>           Kernel;
typedef CGAL::Arr_segment_traits_2<Kernel>      Traits_2;

```

```

typedef Traits_2::Point_2                                Point_2;
typedef Traits_2::X_monotone_curve_2                     Segment_2;
typedef CGAL::Arr_face_extended_dcel<Traits_2, bool>      Dcel;
typedef CGAL::Arrangement_2<Traits_2, Dcel>               Arrangement_2;
typedef CGAL::Arr_face_overlay_traits<Arrangement_2,
                                     Arrangement_2,
                                     Arrangement_2,
                                     std::logical_and<bool> >
                                     Overlay_traits;

int main ()
{
    // Construct the first arrangement, containing a square-shaped face.
    Arrangement_2      arr1;

    Segment_2          s1 (Point_2(2, 2), Point_2(6, 2));
    Segment_2          s2 (Point_2(6, 2), Point_2(6, 6));
    Segment_2          s3 (Point_2(6, 6), Point_2(2, 6));
    Segment_2          s4 (Point_2(2, 6), Point_2(2, 2));

    insert_non_intersecting_curve (arr1, s1);
    insert_non_intersecting_curve (arr1, s2);
    insert_non_intersecting_curve (arr1, s3);
    insert_non_intersecting_curve (arr1, s4);

    // Mark just the bounded face.
    Arrangement_2::Face_iterator  fit;

    CGAL_assertion (arr1.number_of_faces() == 2);
    for (fit = arr1.faces_begin(); fit != arr1.faces_end(); ++fit)
        fit->set_data (fit != arr1.unbounded_face());

    // Construct the second arrangement, containing a rhombus-shaped face.
    Arrangement_2      arr2;

    Segment_2          t1 (Point_2(4, 1), Point_2(7, 4));
    Segment_2          t2 (Point_2(7, 4), Point_2(4, 7));
    Segment_2          t3 (Point_2(4, 7), Point_2(1, 4));
    Segment_2          t4 (Point_2(1, 4), Point_2(4, 1));

    insert_non_intersecting_curve (arr2, t1);
    insert_non_intersecting_curve (arr2, t2);
    insert_non_intersecting_curve (arr2, t3);
    insert_non_intersecting_curve (arr2, t4);

    // Mark just the bounded face.
    CGAL_assertion (arr2.number_of_faces() == 2);
    for (fit = arr2.faces_begin(); fit != arr2.faces_end(); ++fit)
        fit->set_data (fit != arr2.unbounded_face());

    // Compute the overlay of the two arrangements, marking only the faces
    that

```

```

// are intersections of two marked faces in arr1 and arr2,
respectively.
Arrangement_2          overlay_arr;
Overlay_traits          overlay_traits;

overlay (arr1, arr2, overlay_arr, overlay_traits);

// Go over the faces of the overlaid arrangement and print just the
marked
// ones.
Arrangement_2::Ccb_halfedge_circulator    curr;

std::cout << "The union is: ";
for (fit = overlay_arr.faces_begin(); fit != overlay_arr.faces_end();
    ++fit) {
    if (! fit->data())
        continue;

    curr = fit->outer_ccb();
    std::cout << curr->source()->point();
    do {
        std::cout << " --> " << curr->target()->point();
        ++curr;
    } while (curr != fit->outer_ccb());
    std::cout << std::endl;
}

return 0;
}

```

File: examples/Arrangement_on_surface_2/face_extension_overlay.cpp

The next example demonstrates the face overlay of two arrangements that have unbounded faces as well. The first arrangement is formed by the two lines $y = x$ and $y = -x$, that subdivide the plane into four unbounded faces, denoted A , B , C and D . The second arrangement comprises four line segments that form a square-shaped face. When we overlay the two arrangements, each of the four faces A , B , C and D is split into an unbounded face (indexed 1) and a bounded face (indexed 2):

```

#include <string>
#include <boost/lexical_cast.hpp>

#include <CGAL/Exact_predicates_exact_constructions_kernel.h>
#include <CGAL/Arr_linear_traits_2.h>
#include <CGAL/Arrangement_2.h>
#include <CGAL/Arr_extended_dcel.h>
#include <CGAL/Arr_overlay_2.h>
#include <CGAL/Arr_default_overlay_traits.h>

// Define a functor for creating a label from a character and an integer.
struct Overlay_label
{
    std::string operator() (char c, int i) const

```

```

{
    return boost::lexical_cast<std::string>(c) +
           boost::lexical_cast<std::string>(i);
}
};

typedef CGAL::Exact_predicates_exact_constructions_kernel    Kernel;
typedef CGAL::Arr_linear_traits_2<Kernel>                    Traits_2;

30.10 Storing the Curve History

As stated at the beginning of this chapter (Section 30.1), when one constructs an arrangement induced by a set C of arbitrary planar curves, she or he constructs a collection C'' of x -monotone subcurves of C that are pairwise disjoint in their interior, and these subcurves are associated with the arrangement edges (more precisely, with the DCEL halfedges). Doing so, the connection between the originating input curves and the arrangement edges is lost. This loss might be acceptable for some applications. However, in many practical cases it is important to determine the input curves that give rise to the final subcurves.

The *Arrangement_with_history_2*<Traits,Dcel> class-template extends the *Arrangement_2* class by keeping an additional container of input curves representing C , and by maintaining a cross-mapping between these curves and the arrangement edges they induce. The traits class that is used for instantiating the template should be a model of the *ArrangementTraits_2* concept (see Section 30.4.1). That is, it should define the *Curve_2* type (and not just the *X_monotone_curve_2* type). The *Dcel* parameter should model the *ArrangementDcel* concept. Users can use the default DCEL class or an extended DCEL class according to their needs.

30.10.1 Traversing an Arrangement with History

The *Arrangement_with_history_2* class extends the *Arrangement_2* class, thus all the iterator and circulator types that are defined by the arrangement class are also available in *Arrangement_with_history_2*. The reader is referred to Section 30.2.2 for a comprehensive review of these functions.

As mentioned above, the *Arrangement_with_history_2* class maintains a container of input curves, which can be accessed using curve handles. The member function *number_of_curves()* returns the number of input curves stored in the container, while *curves_begin()* and *curves_end()* return *Arrangement_with_history_2::Curve_iterator* objects that define the valid range of curves that induce the arrangement. The value type of this iterator is *Curve_2*. Moreover, the curve-iterator type is equivalent to *Arrangement_with_history_2::Curve_handle*, which is used for accessing the stored curves. Conveniently, the corresponding constant-iterator and constant-handle types are also defined.

As mentioned in the previous paragraph, a *Curve_handle* object *ch* serves as a pointer to a curve stored in an arrangement-with-history instance *arr*. Using this handle, it is possible to obtain the number of arrangement edges this curve induces by calling *arr.number_of_induced_edges(ch)*. The functions *arr.induced_edges_begin(ch)* and *arr.induced_edges_end(ch)* return iterators of type *Arrangement_with_history_2::Induced_edges_iterator* that define the valid range of edges induced by *ch*. The value type of these iterators is *Halfedge_handle*. It is thus possible to traverse all arrangement edges induced by an input curve.

It is also important to be able to perform the inverse mapping. Given an arrangement edge, we would like to be able to determine which input curve induces it. In case the edge represents an overlap of several curves, we should be able to trace all input curves that overlap over this edge. The *Arrangement_with_history_2* class is extended by several member functions that enable such an inverse mapping. Given a halfedge handle *e* in an arrangement with history *arr*, then *arr.number_of_originating_curves(e)* returns the number of curves that induce the edge (which should be 1 in non-degenerate cases, and 2 or more in case of overlaps), while *arr.originating_curves_begin(e)* and *arr.originating_curves_end(e)* return *Arrangement_with_history_2::Originating_curve_iterator* objects that define the range of curves that induce *e*. The value type of these iterator is *Curve_2*.

It is possible to overlay two *Arrangement_with_history_2* instances instantiated by the same traits class. In this case, the resulting arrangement will store a consolidated container of input curves, and automatically preserve the cross-mapping between the arrangement edges and the consolidated curve set. Users can employ an overlay-traits class to maintain any type of auxiliary data stored with the DCEL features (see Section 30.9).

30.10.2 Modifying an Arrangement with History

As the *Arrangement_with_history_2* class extends the *Arrangement_2* class, it inherits the fundamental modification operations, such as *assign()* and *clear()*, from it. The vertex-manipulation functions are also inherited and supported (see Sections 30.2.3 and 30.4.1 for the details). However, there are some fundamental differences between the interfaces of the two classes, which we highlight in this subsection.

The most significant difference between the arrangement-with-history class and the basic arrangement class is the way they handle their input curves. *Arrangement_with_history_2* always stores the *Curve_2* objects that

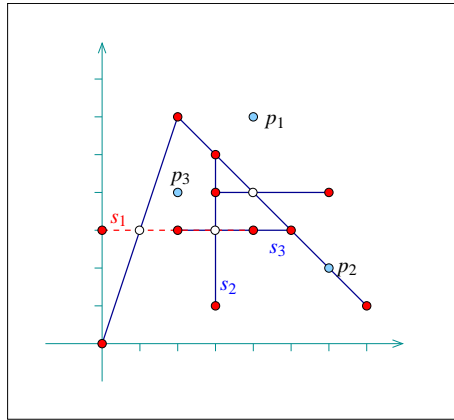

Figure 30.27: An arrangement with history as constructed in *curve_history.cpp*. Note that s_1 and s_3 overlap over two edges. The point-location query points are drawn as lightly shaded dots.

induce it, thus it is impossible to insert x -monotone curves into an arrangement with history. The free *insert_non_intersecting_curve()* and *insert()* that receives x -monotone curve (as well as their aggregated versions) are therefore not available for arrangement-with-history instances and only the free *insert()* and *insert()* functions that receive *Curve_2* (the incremental insertion function and the aggregated insertion function) are supported — see also Section 30.4.1. Notice however that while the incremental insertion function *insert(arr,c)* for an *Arrangement_2* object *arr* does not have a return value, the corresponding arrangement-with-history function returns a *Curve_handle* to the inserted curve.

As we are able to keep track of all edges induced by an input curve, we also provide a free function that removes a curve from an arrangement. By calling *remove(arr,ch)*, where *ch* is a valid curve handle, the given curve is deleted from the curve container, and all edges induced solely by this curve (i.e., excluding overlapping edges) are removed from the arrangement. The function returns the number of edges that have been removed.

In some cases, users may need to operate directly on the arrangement edges. We first mention that the specialized insertion functions (see Section 30.2.3) are not supported, as they accept x -monotone curves. Insertion can only be performed via the free insertion-functions. The other edge-manipulation functions (see Section 30.2.3) are however available, but have a different interface that does not use x -monotone curves:

- Invoking *split_edge(e,p)* splits the edge *e* at a given point *p* that lies in its interior.
- Invoking *merge_edge(e1,e2)* merges the two given edges. There is a precondition that *e1* and *e2* shared a common end-vertex of degree 2, and that the x -monotone subcurves associated with these edges are mergeable.
- It is possible to remove an edge by simply invoking *remove_edge(e)*.

In all cases, the maintenance of cross-pointers for the appropriate input curves will be done automatically.

It should be noted that it is possible to attach observers to an arrangement-with-history instance in order to get detailed notifications of the changes the arrangements undergoes (see Section 30.7 for the details).

30.10.3 Examples

In the following example we construct a simple arrangement of six line segments, as depicted in Figure 30.27, while maintaining the curve history. The example demonstrates the usage of the special traversal functions.

It also shows how to issue point-location queries on the resulting arrangement, using the auxiliary function `point_location_query()` defined in the header file `point_location_utils.h` (see also Section 30.3.1).

```
#include "arr_rational_nt.h"
#include <CGAL/Cartesian.h>
#include <CGAL/Arr_segment_traits_2.h>

#include <CGAL/Arrangement_on_surface_with_history_2.h>
#include <CGAL/Arrangement_with_history_2.h>
#include <CGAL/Arr_simple_point_location.h>

}

// Perform some point-location queries:
Point_location    pl (arr);

Point_2           p1 (4, 6);
point_location_query (pl, p1);
Point_2           p2 (6, 2);
point_location_query (pl, p2);
Point_2           p3 (2, 4);
point_location_query (pl, p3);

return 0;
}

```

File: examples/Arrangement_on_surface_2/curve_history.cpp

The following example demonstrates the usage of the free *remove()* function. We construct an arrangement of nine circles, while keeping a handle to each inserted circle. We then remove the large circle C_0 , which induces

18 edges, as depicted in Figure 30.28. The example also shows how to use the *split_edge()* and *merge_edge()* functions when operating on an arrangement-with-history instance:

```
#include "arr_rational_nt.h"
#include <CGAL/Cartesian.h>
#include <CGAL/Arr_circle_segment_traits_2.h>
#include <CGAL/Arrangement_with_history_2.h>

typedef CGAL::Cartesian<Number_type>          Kernel;
typedef Kernel::Point_2                       Rat_point_2;
typedef Kernel::Circle_2                     Circle_2;
typedef CGAL::Arr_circle_segment_traits_2<Kernel> Traits_2;
typedef Traits_2::Point_2                    Point_2;
typedef Traits_2::Curve_2                    Curve_2;
typedef CGAL::Arrangement_with_history_2<Traits_2> Arr_with_hist_2;
typedef Arr_with_hist_2::Curve_handle        Curve_handle;
typedef CGAL::Arr_walk_along_line_point_location<Arr_with_hist_2> Point_location;

int main ()
{
    // Construct an arrangement containing nine circles: C[0] of radius 2
    // and
    // C[1], ..., C[8] of radius 1.
    const Number_type _7_halves = Number_type (7, 2);
    Arr_with_hist_2    arr;
    Curve_2            C[9];
    Curve_handle       handles[9];
    int                k;

    C[0] = Circle_2 (Rat_point_2 (_7_halves, _7_halves), 4,
        CGAL::CLOCKWISE);
    C[1] = Circle_2 (Rat_point_2 (_7_halves, 6), 1, CGAL::CLOCKWISE);
    C[2] = Circle_2 (Rat_point_2 (5, 6), 1, CGAL::CLOCKWISE);
    C[3] = Circle_2 (Rat_point_2 (6, _7_halves), 1, CGAL::CLOCKWISE);
    C[4] = Circle_2 (Rat_point_2 (5, 2), 1, CGAL::CLOCKWISE);
    C[5] = Circle_2 (Rat_point_2 (_7_halves, 1), 1, CGAL::CLOCKWISE);

30.11 Input/Output Streams

In some cases, one would like to save an arrangement object constructed by some application, so that later on it can be restored. In other cases one would like to create nice drawings that represent arrangements constructed by some application. These drawings can be hard printed or displayed on a computer screen.

30.11.1 Input/Output Stream

Consider an arrangement that represents a very complicated geographical map, and assume that there are various applications that need to answer point-location queries on this map. Naturally, you can store the set of curves that induces the arrangement, but this implies that you would need to construct the arrangement from scratch

each time you need to reuse it. A more efficient solution is to write the arrangement to a file in a format that other applications can read.

This package provides an *inserter* (the << operator) and an *extractor* (the >> operator) for the *Arrangement_2*<*Traits*,*Dcel*> class that inserts and an arrangement object into an output stream and extracts an arrangement object from an input stream respectively. The arrangement is written using a simple predefined ASCII format that encodes the arrangement topology, as well as all geometric entities associated with vertices and edges.

The ability to use the input/output operators, requires that the *Point_2* type and the *X_monotone_curve_2* type defined by the traits class both support the << and >> operators. The *Arr_conic_traits_2* class (see Section 30.6.5), the *Arr_rational_arc_traits_2* class (see Section 30.6.6), and the *Arr_linear_traits_2* class (see Section 30.6.2) currently do not provide these operators for the geometric types they define. Thus, only arrangements of line segments or of polylines can be written or read.

The following example constructs the arrangement depicted in Figure 30.7 and writes it to an output file. It also demonstrates how to re-read the arrangement from a file:

```
#include "arr_rational_nt.h"
#include <CGAL/Cartesian.h>
#include <CGAL/Arr_segment_traits_2.h>
#include <CGAL/Arrangement_2.h>
#include <CGAL/IO/Arr_iostream.h>
#include <fstream>

#include "point_location_utils.h"

typedef CGAL::Cartesian<Number_type>           Kernel;
typedef CGAL::Arr_segment_traits_2<Kernel>      Traits_2;
typedef CGAL::Arrangement_2<Traits_2>          Arrangement_2;

int main ()
{
    // Construct the arrangement.
    Arrangement_2    arr;

    construct_segments_arr (arr);

    std::cout << "Writing an arrangement of size:" << std::endl
               << "    V = " << arr.number_of_vertices()
               << ",    E = " << arr.number_of_edges()
               << ",    F = " << arr.number_of_faces() << std::endl;

    // Write the arrangement to a file.
    std::ofstream    out_file ("arr_ex_io.dat");

    out_file << arr;
    out_file.close();

    // Read the arrangement from the file.
    Arrangement_2    arr2;
    std::ifstream    in_file ("arr_ex_io.dat");

    in_file >> arr2;
    in_file.close();
}
```

```

std::cout << "Read an arrangement of size:" << std::endl
          << "    V = " << arr2.number_of_vertices()
          << ",    E = " << arr2.number_of_edges()
          << ",    F = " << arr2.number_of_faces() << std::endl;

return (0);
}

```

30.11.2 Arrangements with Auxiliary Data

The inserter and extractor both ignore any auxiliary data stored with the arrangement features. Thus, they are ideal for arrangements instantiated using the `Arr_default_dcel` class. However, as explained in Section 30.8, one can easily extend the arrangement faces by using the `Arr_face_extended_dcel` template, or extend all DCEL records by using the `Arr_extended_dcel` template. In such cases, it might be crucial that the auxiliary data fields are written to the file and read from there.

The arrangement package includes the free functions `write(arr, os, formatter)`, which writes the arrangement `arr` to an output stream `os`, and `read(arr, is, formatter)`, which reads the arrangement `arr` from an input stream `is`. Both operations are performed using a `formatter` object, which defines the I/O format. The package contains three formatter classes:

- `Arr_text_formatter<Arrangement>` defines a simple textual I/O format for the arrangement topology and geometry, disregarding any auxiliary data that may be associated with the arrangement features. This is the default formatter used by the arrangement inserter and the arrangement extractor, as defined above.
- `Arr_face_extended_text_formatter<Arrangement>` operates on arrangements whose DCEL representation is based on the `Arr_face_extended_dcel<Traits, FaceData>` class (see Section 30.8.1). It supports reading and writing the auxiliary data objects stored with the arrangement faces provided that the `FaceData` class supports an inserter and an extractor.
- `Arr_extended_dcel_text_formatter<Arrangement>` operates on arrangements whose DCEL representation is based on the `Arr_extended_dcel<Traits, VertexData, HalfedgeData, FaceData>` class (see Section 30.8.2). It supports reading and writing the auxiliary data objects stored with the arrangement vertices, edges and faces, provided that the `VertexData`, `HalfedgeData` and `FaceData` classes all have inserters and extractors.

The following example constructs the same arrangement as the example `dcel_extension` does (see Section 30.8.2), depicted in Figure 30.25, and writes it to an output file. It also demonstrates how to re-read the arrangement from a file:

```

#include "arr_rational_nt.h"
#include <CGAL/Cartesian.h>
#include <CGAL/Arr_segment_traits_2.h>
#include <CGAL/Arr_extended_dcel.h>
#include <CGAL/Arrangement_2.h>

```

```

#include <CGAL/IO/Arr_text_formatter.h>
#include <CGAL/IO/Arr_iostream.h>
#include <fstream>

enum Color {BLUE, RED, WHITE};

std::ostream& operator<< (std::ostream& os, const Color& color)
{
    switch (color)
    {
        case BLUE:  os << "BLUE";  break;
        case RED:   os << "RED";   break;
        case WHITE: os << "WHITE"; break;
        default:    os << "ERROR!";
    }
    return (os);
}

std::istream& operator>> (std::istream& is, Color& color)
{
    std::string str;
    is >> str;

    if (str == "BLUE")
        color = BLUE;
    else if (str == "RED")
        color = RED;
    else if (str == "WHITE")
        color = WHITE;

    return (is);
}

}

```

File: examples/Arrangement_on_surface_2/dcel_extension_io.cpp

You may develop your own own formatter classes — models of the *ArrangementInputFormatter* and *ArrangementOutputFormatter* concepts, as defined in the Reference Manual. Doing so, you can define other I/O formats, such as an XML-based format or a binary format.

— advanced —

30.11.3 Arrangements with Curve History

Section 30.10 introduces the *Arrangement_with_history_2*<*Traits*,*Dcel*> class, which saves the set of curves inducing an arrangement and maintains the relations between these curves and the edges they induce. Naturally, when reading or writing an arrangement-with-history instance we would like this information to be saved to the output stream or restored from the input stream alongside with the basic arrangement structure.

The arrangement package supplies an inserter and an extractor for the *Arrangement_with_history_2*<*Traits*,*Dcel*> class. The arrangement is represented using a simple predefined ASCII format. An object of the *Arrangement_with_history_2*<*Traits*,*Dcel*> type can be saved and restored, as long as the *Curve_2* type defined by the traits class — as well as the *Point_2* type and the *X_monotone_curve_2* types — support the << and >> operators.

The following example constructs the same arrangement as example *curve_history* does (see Section 30.10.3), depicted in Figure 30.27, and writes it to an output file. It also demonstrates how to re-read the arrangement-with-history from a file:

```
#include "arr_rational_nt.h"
```

```

#include <CGAL/Cartesian.h>
#include <CGAL/Arr_segment_traits_2.h>
#include <CGAL/Arrangement_with_history_2.h>
#include <CGAL/IO/Arr_with_history_iostream.h>
#include <fstream>

typedef CGAL::Cartesian<Number_type>           Kernel;
typedef CGAL::Arr_segment_traits_2<Kernel>      Traits_2;
typedef Traits_2::Point_2                      Point_2;
typedef Traits_2::Curve_2                     Segment_2;
typedef CGAL::Arrangement_with_history_2<Traits_2> Arr_with_hist_2;

int main ()
{
    Arr_with_hist_2    arr;

    // Insert six additional segments aggregately:
    Segment_2          segs[6];
    segs[0] = Segment_2 (Point_2 (2, 6), Point_2 (7, 1));
    segs[1] = Segment_2 (Point_2 (3, 2), Point_2 (3, 5));
    segs[2] = Segment_2 (Point_2 (2, 3), Point_2 (5, 3));
    segs[3] = Segment_2 (Point_2 (2, 6), Point_2 (7, 1));
    segs[4] = Segment_2 (Point_2 (0, 0), Point_2 (2, 6));
    segs[5] = Segment_2 (Point_2 (3, 4), Point_2 (6, 4));
    insert (arr, segs, segs + 6);

    std::cout << "Writing an arrangement of "
                << arr.number_of_curves() << " input segments:" << std::endl
                << "    V = " << arr.number_of_vertices()
                << ",    E = " << arr.number_of_edges()
                << ",    F = " << arr.number_of_faces() << std::endl;

    // Write the arrangement to a file.
    std::ofstream    out_file ("arr_ex_io_hist.dat");

    out_file << arr;
    out_file.close();

    // Read the arrangement from the file.
    Arr_with_hist_2  arr2;
    std::ifstream    in_file ("arr_ex_io_hist.dat");

    in_file >> arr2;
    in_file.close();

    std::cout << "Read an arrangement of "
                << arr2.number_of_curves() << " input segments:" << std::endl
                << "    V = " << arr2.number_of_vertices()
                << ",    E = " << arr2.number_of_edges()
                << ",    F = " << arr2.number_of_faces() << std::endl;

    return (0);
}

```

File: examples/Arrangement_on_surface_2/io_curve_history.cpp

—advanced—

The arrangement package also includes the free functions *write(arr, os, formatter)* and *read(arr, os, formatter)* that operate on a given arrangement-with-history instance *arr*. Both functions are parameterized by a *formatter* object, which define the I/O format. The package contains a template called, *Arr_with_hist_text_formatter<ArrangementFormatter>*, which extends an arrangement formatter class (see Section 30.11.2) and defines a simple textual input/output format.

—advanced—

30.11.4 Output QT-widget Stream

You can display the drawings of arrangements in a graphical window powered by QT interactively. All you need to do is follow the guidelines for handling *Qt_widget* objects, and apply the *inserter*, which inserts an arrangement into a *Qt_widget* stream to complete the drawing.

The ability to use this output operator, requires that the *Point_2* and *X_monotone_curve_2* types defined by the traits class both support the *<<* operator that inserts the respective geometric object into a *Qt_widget* stream. The *Arr_rational_arc_traits_2* class (see Section 30.6.6) and the *Arr_linear_traits_2* class (see Section 30.6.2) currently do not provide this operator for the geometric types they define. Thus, only arrangements of line segments, polylines, or conic arcs can be written. The *<<* operator for polylines and conic arcs defined in *CGAL/IO/Qt_widget_Polyline_2.h* and *CGAL/IO/Qt_widget_Conic_arc_2.h* must be explicitly included, to insert polylines and conic arcs respectively into *Qt_widget* streams.

30.12 Adapting to BOOST Graphs

BOOST¹⁷ is a collection of portable C++ libraries that extend the Standard Template Library (STL). The BOOST Graph Library (BGL), which one of the libraries in the collection, offers an extensive set of generic graph algorithms parameterized through templates. As our arrangements are embedded as planar graphs, it is only natural to extend the underlying data structure with the interface that the BGL expects, and gain the ability to perform the operations that the BGL supports, such as shortest-path computation. This section describes how apply the graph algorithms implemented in the BGL to *Arrangement_2* instances.

An instance of *Arrangement_2* is adapted to a BOOST graph through the provision of a set of free functions that operate on the arrangement features and conform with the relevant BGL concepts. Besides the straightforward adaptation, which associates a vertex with each DCEL vertex and an edge with each DCEL halfedge, the package also offer a *dual* adaptor, which associates a graph vertex with each DCEL face, such that two vertices are connected, iff there is a DCEL halfedge that connects the two corresponding faces.

30.12.1 The Primal Arrangement Representation

Arrangement instances are adapted to BOOST graphs by specializing the *boost:graph_traits* template for *Arrangement_2* instances. The graph-traits states the graph concepts that the arrangement class models (see below) and defines the types required by these concepts.

¹⁷See also BOOST's homepage at: www.boost.org.

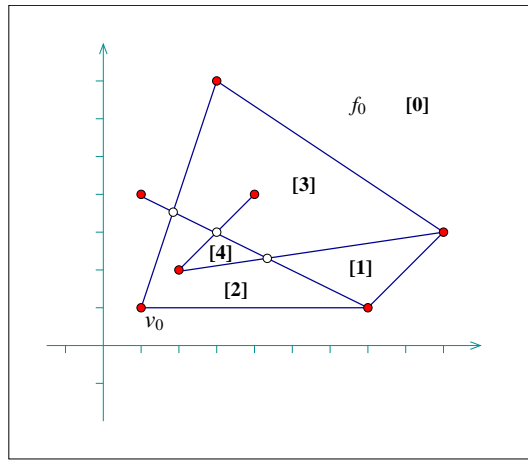

Figure 30.29: An arrangement of 7 line segments, as constructed by *bgl_primal_adapter.cpp* and *bgl_dual_adapter.cpp*. The breadth-first visit times for the arrangement faces, starting from the unbounded face f_0 , are shown in brackets.

In this specialization the *Arrangement_2* vertices correspond to the graph vertices, where two vertices are adjacent if there is at least one halfedge connecting them. More precisely, *Arrangement_2::Vertex_handle* is the graph-vertex type, while *Arrangement_2::Halfedge_handle* is the graph-edge type. As halfedges are directed, we consider the graph to be directed as well. Moreover, as several interior-disjoint x -monotone curves (say circular arcs) may share two common endpoints, inducing an arrangement with two vertices that are connected with several edges, we allow parallel edges in our BOOST graph.

Given an *Arrangement_2* instance, we can efficiently traverse its vertices and halfedges. Thus, the arrangement graph is a model of the concepts *VertexListGraph* and *EdgeListGraph* introduced by the BGL. At the same time, we use an iterator adapter of the circulator over the halfedges incident to a vertex (*Halfedge_around_vertex_circulator* — see Section 30.2.2), so it is possible to go over the ingoing and outgoing edges of a vertex in linear time. Thus, our arrangement graph is a model of the concept *BidirectionalGraph* (this concept refines *IncidenceGraph*, which requires only the traversal of outgoing edges).

It is important to notice that the vertex descriptors we use are *Vertex_handle* objects and *not* vertex indices. However, in order to gain more efficiency in most BGL algorithm, it is better to have them indexed $0, 1, \dots, (n - 1)$, where n is the number of vertices. We therefore introduce the *Arr_vertex_index_map<Arrangement>* class-template, which maintains a mapping of vertex handles to indices, as required by the BGL. An instance of this class must be attached to a valid arrangement vertex when it is created. It uses the notification mechanism (see Section 30.7) to automatically maintain the mapping of vertices to indices, even when new vertices are inserted into the arrangement or existing vertices are removed.

In most algorithm provided by the BGL, the output is given by *property maps*, such that each map entry corresponds to a vertex. For example, when we compute the shortest paths from a given source vertex s to all other vertices we can obtain a map of distances and a map of predecessors — namely for each v vertex we have its distance from s and a descriptor of the vertex that precedes v in the shortest path from s . If the vertex descriptors are simply indices, one can use vectors to efficiently represent the property maps. As this is not the case with the arrangement graph, we offer the *Arr_vertex_property_map<Arrangement, Type>* template allows for an efficient mapping of *Vertex_handle* objects to properties of type *Type*. Note however that unlike the *Arr_vertex_index_map* class, the vertex property-map class is not kept synchronized with the number of vertices in the arrangement, so it should not be reused in calls to BGL functions in case the arrangement is modified in between these calls.

In the following example we construct an arrangement of 7 line segments, as shown in Figure 72.1, then use

Dijkstra's shortest-paths algorithm from the BGL to compute the graph distance of all vertices from the leftmost vertex in the arrangement v_0 . Note the usage of the *Arr_vertex_index_map* and the *Arr_vertex_property_map* classes. The latter one, instantiated by the type *double* is used to map vertices to their distances from v_0 .

30.12.2 The Dual Arrangement Representation

It is possible to give a dual graph representation for an arrangement instance, such that each arrangement face corresponds to a graph vertex and two vertices are adjacent iff the corresponding faces share a common edge on their boundaries. This is done by specializing the *boost.graph_traits* template for *Dual<Arrangement_2>* instances, where *Dual<Arrangement_2>* is a template specialization that gives a dual interpretation to an arrangement instance.

In dual representation, *Arrangement_2::Face_handle* is the graph-vertex type, while *Arrangement_2::Halfedge_handle* is the graph-edge type. We treat the graph edges as directed, such that a halfedge *e* is directed from *f*₁, which is its incident face, to *f*₂, which is the incident face of its twin halfedge. As two arrangement faces may share more than a single edge on their boundary, we allow parallel edges in our BOOST graph. As is the case in the primal graph, the dual arrangement graph is also a model of the concepts *VertexListGraph*, *EdgeListGraph* and *BidirectionalGraph* (thus also of *IncidenceGraph*).

Since we use *Face_handle* objects as the vertex descriptors, we define the *Arr_face_index_map<Arrangement>* class-template, which maintains an efficient mapping of face handles to indices. We also provide the template *Arr_face_property_map<Arrangement,Type>* for associating arbitrary data with the arrangement faces.

In the following example we construct the same arrangement as in example *bgl_primal_adapter.cpp* (see Figure 72.1), and perform breadth-first search on the graph faces, starting from the unbounded face. We extend the DCEL faces with an unsigned integer, marking the discover time of the face and use a breadth-first-search visitor to obtain these times and update the faces accordingly:

```
#include "arr_rational_nt.h"
#include <CGAL/Cartesian.h>
#include <CGAL/Arr_segment_traits_2.h>
#include <CGAL/Arr_extended_dcel.h>
#include <CGAL/Arrangement_2.h>

#include <climits>
#include <boost/graph/dijkstra_shortest_paths.hpp>

#include <CGAL/graph_traits_Dual_Arrangement_2.h>
#include <CGAL/Arr_face_index_map.h>

#include "arr_print.h"

typedef CGAL::Cartesian<Number_type>           Kernel;
typedef CGAL::Arr_segment_traits_2<Kernel>      Traits_2;
typedef Traits_2::Point_2                      Point_2;
typedef Traits_2::X_monotone_curve_2           Segment_2;
typedef CGAL::Arr_face_extended_dcel<Traits_2, unsigned int> Dcel;
typedef CGAL::Arrangement_2<Traits_2, Dcel>      Arrangement_2;
typedef CGAL::Dual<Arrangement_2>              Dual_arrangement_2;

// A BFS visitor class that associates each vertex with its discover
// time.
// In our case graph vertices represent arrangement faces.
template <class IndexMap>
class Discover_time_bfs_visitor : public boost::default_bfs_visitor
{
```

```

private:

    const IndexMap *index_map;          // Mapping vertices to indices.
    unsigned int    time;                // The current time stamp.

public:

    // Constructor.
    Discover_time_bfs_visitor (const IndexMap& imap) :
        index_map (&imap),
        time (0)
    {}

    // Write the discover time for a given vertex.
    template <typename Vertex, typename Graph>
    void discover_vertex(Vertex u, const Graph& /* g */)
    {
        u->set_data (time);
        time++;
    }
};

int main ()
{
    Arrangement_2    arr;

    // Construct an arrangement of seven intersecting line segments.
    insert (arr, Segment_2 (Point_2 (1, 1), Point_2 (7, 1)));
    insert (arr, Segment_2 (Point_2 (1, 1), Point_2 (3, 7)));
    insert (arr, Segment_2 (Point_2 (1, 4), Point_2 (7, 1)));
    insert (arr, Segment_2 (Point_2 (2, 2), Point_2 (9, 3)));
    insert (arr, Segment_2 (Point_2 (2, 2), Point_2 (4, 4)));
    insert (arr, Segment_2 (Point_2 (7, 1), Point_2 (9, 3)));
    insert (arr, Segment_2 (Point_2 (3, 7), Point_2 (9, 3)));

    // Create a mapping of the arrangement faces to indices.
    CGAL::Arr_face_index_map<Arrangement_2>    index_map (arr);

    // Perform breadth-first search from the unbounded face, and use the
    // BFS
    // visitor to associate each arrangement face with its discover time.
    Discover_time_bfs_visitor<CGAL::Arr_face_index_map<Arrangement_2> >
        bfs_visitor (index_map);
    Arrangement_2::Face_handle    uf = arr.unbounded_face();

    boost::breadth_first_search (Dual_arrangement_2 (arr), uf,
        boost::vertex_index_map (index_map).
        visitor (bfs_visitor));

    // Print the results:
    Arrangement_2::Face_iterator    fit;

    for (fit = arr.faces_begin(); fit != arr.faces_end(); ++fit) {
        std::cout << "Discover time " << fit->data() << " for ";
    }
}

```

```

    if (fit != uf) {
        std::cout << "face ";
        print_ccb<Arrangement_2> (fit->outer_ccb());
    }
    else
        std::cout << "the unbounded face." << std::endl;
}

return 0;
}

```

30.13 How To Speed Up Your Computation

Before the specific tips, we remind you that compiling programs with debug flags disabled and with optimization flags enabled significantly reduces the running time.

1. When the curves to be inserted into an arrangement are x -monotone and pairwise disjoint in their interior to start with, then it is more efficient (in running time) and less demanding (in traits-class functionality) to use the non-intersection insertion-functions instead of the general ones; e.g., *insert()*.
2. When the curves to be inserted into an arrangement are segments that are pairwise disjoint in their interior, it is more efficient to use the traits class *Arr_non_caching_segment_traits_2* rather than the default one (*Arr_segment_traits_2*).

If the segments may intersect each other, the default traits class *Arr_segment_traits_2* can be safely used with the somehow limited number type *Quotient<MP_float>*.

On rare occasions the traits class *Arr_non_caching_segment_traits_2* exhibits slightly better performance than the default one (*Arr_segment_traits_2* even when the segments intersect each other, due to the small overhead of the latter (optimized) traits class. (For example, when the so called LEDA rational kernel is used).

3. Prior knowledge of the combinatorial structure of the arrangement can be used to accelerate operations that insert x -monotone curves, whose interior is disjoint from existing edges and vertices of the arrangement. The specialized insertion functions, i.e., *insert_in_face_interior()*, *insert_from_left_vertex()*, *insert_from_right_vertex()*, and *insert_at_vertices()* can be used according to the available information. These functions hardly involve any geometric operations, if at all. They accept topologically related parameters, and use them to operate directly on the DCEL records, thus saving algebraic operations, which are especially expensive when high-degree curves are involved.

A polygon, represented by a list of segments along its boundary, can be inserted into an empty arrangement as follows. First, one segment is inserted using *insert_in_face_interior()* into the unbounded face. Then, a segment with a common end point is inserted using either *insert_from_left_vertex()* or *insert_from_right_vertex()*, and so on with the rest of the segments except for the last, which is inserted using *insert_at_vertices()*, as both endpoints of which are the mapping of known vertices.

4. The main trade-off among point-location strategies, is between time and storage. Using the naive or walk strategies, for example, takes more query time but does not require preprocessing or maintenance of auxiliary structures and saves storage space.

5. If point-location queries are not performed frequently, but other modifying functions, such as removing, splitting, or merging edges are, then using a point-location strategy that does not require the maintenance of auxiliary structures, such as the naive or walk strategies, is preferable.
6. There is a trade-off between two modes of the trapezoidal RIC strategy that enables the user to choose whether preprocessing should be performed or not. If preprocessing is not used, the creation of the structure is faster. However, for some input sequences the structure might be unbalanced and therefore queries and updates might take longer, especially, if many removal and split operations are performed.
7. When the curves to be inserted into an arrangement are available in advance (as opposed to supplied on-line), it is advised to use the more efficient aggregate (sweep-based) insertion over the incremental insertion; e.g., *insert()*.
8. The various traits classes should be instantiated with an exact number type to ensure robustness, when the input of the operations to be carried out might be degenerate, although inexact number types could be used at the user's own risk.
9. Maintaining short bit-lengths of coordinate representations may drastically decrease the time consumption of arithmetic operations on the coordinates. This can be achieved by caching certain information or normalization (of rational numbers). However, both solutions should be used cautiously, as the former may lead to an undue space consumption, and indiscriminate normalization may considerably slow down the overall process.
10. Geometric functions (e.g., traits methods) dominate the time consumption of most operations. Thus, calls to such function should be avoided or at least their number should be decreased, perhaps at the expense of increased combinatorial-function calls or increased space consumption. For example, repetition of geometric-function calls could be avoided by storing the results obtained by the first call, and reusing them when needed.

Design and Implementation History

The code of this package is the result of a long development process. Initially (and until version 3.1), the code was spread among several components, namely, *Topological_map*, *Planar_map_2*, *Planar_map_with_intersections_2* and *Arrangement_2*, that were developed by Ester Ezra, Eyal Flato, Efi Fogel, Dan Halperin, Iddo Hanniel, Idit Haran, Shai Hirsch, Eugene Lipovetsky, Oren Nechushtan, Sigal Raab, Ron Wein, Baruch Zukerman, and Tali Zvi.

In version 3.2, as part of the ACS project, the packages have gone through a major re-design, resulting in an improved and unified *2D Arrangements* package. The code of the new package was restructured and developed by Efi Fogel, Idit Haran, Ron Wein, and Baruch Zukerman. This version included for the first time a new geometry-traits class that handles circular and linear curves, and is based on the circular kernel. The circular kernel was developed by Monique Teillaud, Sylvain Pion, and Julien Hazebrouck.

Version 3.3 features arrangements of unbounded curves for the first time. The design and development of this feature required yet another restructuring of the entire package. All this was done by Eric Berberich, Efi Fogel, Dan Halperin, Ophir Setter, and Ron Wein. Michael Hemmer helped tuning up parts of the geometry-traits concept related to unbounded curves.

Version 3.7 introduced a geometry-traits class that handles planar algebraic curves of arbitrary degree. It was developed by Eric Berberich and Michael Kerber.

2D Arrangements

Reference Manual

Ron Wein, Efi Fogel, Baruch Zukerman, Dan Halperin, and Eric Berberich

Given a set C of planar curves, the *arrangement* $\mathcal{A}(C)$ is the subdivision of the plane induced by the curves in C into maximally connected cells. The cells can be 0-dimensional (*vertices*), 1-dimensional (*edges*) or 2-dimensional (*faces*).

The class `Arrangement_2<Traits,Dcel>` encapsulates a data structure that maintains arrangements of arbitrary bounded planar curves. It comes with a variety of algorithms that operate on planar arrangement, such as point-location queries and overlay computations, which are implemented as peripheral classes or as free (global) functions.

CGAL::Arrangement_2<Traits,Dcel>

Definition

An object *arr* of the class *Arrangement_2<Traits,Dcel>* represents the planar subdivision induced by a set of *x*-monotone curves and isolated points into maximally connected cells. The arrangement is represented as a doubly-connected edge-list (DCEL) such that each DCEL vertex is associated with a point of the plane and each edge is associated with an *x*-monotone curve whose interior is disjoint from all other edges and vertices. Recall that an arrangement edge is always comprised of a pair of twin DCEL halfedges.

The *Arrangement_2<Traits,Dcel>* template has two parameters:

- The *Traits* template-parameter should be instantiated with a model of the *ArrangementBasicTraits_2* concept. The traits class defines the types of *x*-monotone curves and two-dimensional points, namely *X_monotone_curve_2* and *Point_2*, respectively, and supports basic geometric predicates on them.
- The *Dcel* template-parameter should be instantiated with a class that is a model of the *ArrangementDcel* concept. The value of this parameter is by default *Arr_default_dcel<Traits>*.

The available traits classes and DCEL classes are described below.

```
#include <CGAL/Arrangement_2.h>
```

Types

<i>typedef Arrangement_2<Traits_2,Dcel></i>	<i>Self</i> ;	a private type used as an abbreviation of the <i>Arrangement_2<Traits,Dcel></i> type hereafter.
<i>Arrangement_2<Traits,Dcel>:: Traits_2</i>		the traits class in use.
<i>Arrangement_2<Traits,Dcel>:: Dcel</i>		the DCEL representation of the arrangement.
<i>typedef typename Traits_2::Point_2</i>	<i>Point_2</i> ;	the point type, as defined by the traits class.
<i>typedef typename Traits_2::X_monotone_curve_2</i>	<i>X_monotone_curve_2</i> ;	the <i>x</i> -monotone curve type, as defined by the traits class.
<i>typedef typename Dcel::Size</i>	<i>Size</i> ;	the size type (equivalent to <i>size_t</i>).
<i>Arrangement_2<Traits,Dcel>:: Vertex</i>		represents a 0-dimensional cell in the subdivision. A vertex is always associated with a point.
<i>Arrangement_2<Traits,Dcel>:: Halfedge</i>		represents (together with its twin — see below) a 1-dimensional cell in the subdivision. A halfedge is always associated with an <i>x</i> -monotone curve.
<i>Arrangement_2<Traits,Dcel>:: Face</i>		represents a 2-dimensional cell in the subdivision.

The following handles, iterators, and circulators all have respective constant counterparts (for example, in addition to *Vertex_iterator* the type *Vertex_const_iterator* is also defined). See [MS96] for a discussion of constant versus mutable iterator types. The mutable types are assignable to their constant counterparts.

Vertex_iterator, *Halfedge_iterator*, and *Face_iterator* are equivalent to the respective handle types (namely, *Vertex_handle*, *Halfedge_handle*, and *Face_handle*). Thus, wherever the handles appear in function parameter lists, the respective iterators can be passed as well.

<i>Arrangement_2<Traits,Dcel>:: Vertex_handle</i>	a handle for an arrangement vertex.
<i>Arrangement_2<Traits,Dcel>:: Halfedge_handle</i>	a handle for a halfedge. The halfedge and its twin form together an arrangement edge.
<i>Arrangement_2<Traits,Dcel>:: Face_handle</i>	a handle for an arrangement face.
<i>Arrangement_2<Traits,Dcel>:: Vertex_iterator</i>	a bidirectional iterator over the vertices of the arrangement. Its value-type is <i>Vertex</i> .
<i>Arrangement_2<Traits,Dcel>:: Halfedge_iterator</i>	a bidirectional iterator over the halfedges of the arrangement. Its value-type is <i>Halfedge</i> .
<i>Arrangement_2<Traits,Dcel>:: Edge_iterator</i>	a bidirectional iterator over the edges of the arrangement. (That is, it skips every other halfedge.) Its value-type is <i>Halfedge</i> .
<i>Arrangement_2<Traits,Dcel>:: Face_iterator</i>	a bidirectional iterator over the faces of arrangement. Its value-type is <i>Face</i> .
<i>Arrangement_2<Traits,Dcel>:: Unbounded_face_iterator</i>	a bidirectional iterator over the unbounded faces of arrangement. Its value-type is <i>Face</i> .
<i>Arrangement_2<Traits,Dcel>:: Halfedge_around_vertex_circulator</i>	a bidirectional circulator over the halfedges that have a given vertex as their target. Its value-type is <i>Halfedge</i> .
<i>Arrangement_2<Traits,Dcel>:: Ccb_halfedge_circulator</i>	a bidirectional circulator over the halfedges of a CCB (connected component of the boundary). Its value-type is <i>Halfedge</i> . Each bounded face has a single CCB representing its outer boundary, and may have several inner CCBs representing its holes.
<i>Arrangement_2<Traits,Dcel>:: Hole_iterator</i>	a bidirectional iterator over the holes (i.e., inner CCBs) contained inside a given face. Its value type is <i>Ccb_halfedge_circulator</i> .
<i>Arrangement_2<Traits,Dcel>:: Isolated_vertex_iterator</i>	a bidirectional iterator over the isolated vertices contained inside a given face. Its value type is <i>Vertex</i> .

Creation

<i>Arrangement_2<Traits,Dcel> arr;</i>	constructs an empty arrangement containing one unbounded face, which corresponds to the entire plane.
--	---

Arrangement_2<*Traits*,*Dcel*> *arr*(*Self* *other*); copy constructor.

Arrangement_2<*Traits*,*Dcel*> *arr*(*const Traits_2* **traits*);

constructs an empty arrangement that uses the given *traits* instance for performing the geometric predicates.

Assignment Methods

Self & *arr* = *other* assignment operator.

void *arr.assign*(*Self* *other*) assigns the contents of another arrangement.

void *arr.clear*() clears the arrangement.

Access Functions

*Traits_2** *arr.get_traits*() returns the traits object used by the arrangement instance. A *const* version is also available.

bool *arr.is_empty*() determines whether the arrangement is empty (contains only the unbounded face, with no vertices or edges).

All *_begin*() and *_end*() methods listed below also have *const* counterparts, returning constant iterators instead of mutable ones:

• Accessing the Arrangement Vertices:

Size *arr.number_of_vertices*() returns the number of vertices in the arrangement.

Size *arr.number_of_isolated_vertices*() returns the total number of isolated vertices in the arrangement.

Vertex_iterator *arr.vertices_begin*() returns the begin-iterator of the vertices in the arrangement.

Vertex_iterator *arr.vertices_end*() returns the past-the-end iterator of the vertices in the arrangement.

Size *arr.number_of_vertices_at_infinity*() returns the number of arrangement vertices that lie at infinity and are not associated with valid points. Such vertices are not considered to be regular arrangement vertices and *arr.number_of_vertices*() does not count them.

• Accessing the Arrangement Edges:

<i>Size</i>	<i>arr.number_of_halfedges()</i>	returns the number of halfedges in the arrangement.
<i>Halfedge_iterator</i>	<i>arr.halfedges_begin()</i>	returns the begin-iterator of the halfedges in the arrangement.
<i>Halfedge_iterator</i>	<i>arr.halfedges_end()</i>	returns the past-the-end iterator of the halfedges in the arrangement.
<i>Size</i>	<i>arr.number_of_edges()</i>	returns the number of edges in the arrangement (equivalent to <i>arr.number_of_halfedges() / 2</i>).
<i>Edge_iterator</i>	<i>arr.edges_begin()</i>	returns the begin-iterator of the edges in the arrangement.
<i>Edge_iterator</i>	<i>arr.edges_end()</i>	returns the past-the-end iterator of the edges in the arrangement.
● Accessing the Arrangement Faces:		
<i>Face_handle</i>	<i>arr.unbounded_face()</i>	returns a handle for an unbounded face of the arrangement. In case the arrangement comprises only bounded curves, there is a single unbounded face and the function returns a handle to it. Otherwise, a handle to an arbitrary unbounded face is returned.
<i>Size</i>	<i>arr.number_of_faces()</i>	returns the number of faces in the arrangement.
<i>Face_iterator</i>	<i>arr.faces_begin()</i>	returns the begin-iterator of the faces in the arrangement.
<i>Face_iterator</i>	<i>arr.faces_end()</i>	returns the past-the-end iterator of the faces in the arrangement.
<i>Size</i>	<i>arr.number_of_unbounded_faces()</i>	returns the number of unbounded faces in the arrangement. Note <i>arr.number_of_faces()</i> also counts the unbounded faces of the arrangement.
<i>Unbounded_face_iterator</i>	<i>arr.unbounded_faces_begin()</i>	returns the begin-iterator of the unbounded faces in the arrangement.
<i>Unbounded_face_iterator</i>	<i>arr.unbounded_faces_end()</i>	returns the past-the-end iterator of the unbounded faces in the arrangement.
<i>Face_handle</i>	<i>arr.fictitious_face()</i>	returns a handle to the fictitious face of the arrangement. If the arrangement is not unbounded, there is no fictitious face. In this case the result is not deterministic. A const version is also available.

Casting away Constness

It is sometime necessary to convert a constant (non-mutable) handle to a mutable handle. For example, the result of a point-location query is a non-mutable handle for the arrangement cell containing the query point. Assume that the query point lies on a edge, so we obtain a *Halfedge_const_handle*; if we wish to use this handle and remove the edge, we first need to cast away its “constness”.

Vertex_handle *arr.non_const_handle(Vertex_const_handle v)*

casts the given constant vertex handle to an equivalent mutable handle.

Halfedge_handle *arr.non_const_handle(Halfedge_const_handle e)*

casts the given constant halfedge handle to an equivalent mutable handle.

Face_handle *arr.non_const_handle(Face_const_handle f)*

casts the given constant face handle to an equivalent mutable handle.

Modifiers

• Specialized Insertion Methods:

Vertex_handle *arr.insert_in_face_interior(Point_2 p, Face_handle f)*

inserts the point *p* into the arrangement as an isolated vertex in the interior of the face *f* and returns a handle for the newly created vertex.

Precondition: *p* lies in the interior of the face *f*.

Halfedge_handle *arr.insert_in_face_interior(X_monotone_curve_2 c, Face_handle f)*

inserts the curve *c* that is entirely contained in the interior of a given face *f*. If *c* is a bounded curve two new vertices that correspond to *c*'s endpoints are created and connected with a newly created halfedge pair, which forms a new hole (inner component) in the face *f*. If *c* is unbounded, at least one of the two vertices that represents its end lies at infinity, and its creation modifies the outer boundary of *f*. The function returns a handle for one of the new halfedges corresponding to the inserted curve, directed in lexicographic increasing order (from left to right).

Precondition: *c* lies entirely in the interior of the face *f* and is disjoint from all existing arrangement vertices and edges (in particular, both its endpoints are not already associated with existing arrangement vertices).

Precondition: In case *c* is an unbounded curve, *f* must be an unbounded face.

Halfedge_handle *arr.insert_from_left_vertex(X_monotone_curve_2 c, Vertex_handle v)*

inserts the curve *c* into the arrangement, such that its left endpoint corresponds to a given arrangement vertex. As a result, a new vertex that correspond to *c*'s right endpoint is created and connected to *v* with a newly created halfedge pair. If *c* has an unbounded right end, the new vertex lies at infinity and the unbounded face that contains the interior of the curve is split. The function returns a handle for one of the new halfedges corresponding to the inserted curve, directed towards the newly created vertex — that is, directed in lexicographic increasing order (from left to right).

Precondition: The interior of *c* is disjoint from all existing arrangement vertices and edges.

Precondition: *v* is associated with the left endpoint of *c*.

Precondition: The right endpoint of *c* is not already associated with an existing arrangement vertex.

Halfedge_handle *arr.insert_from_right_vertex(X_monotone_curve_2 c, Vertex_handle v)*

inserts the curve *c* into the arrangement, such that its right endpoint corresponds to a given arrangement vertex. As a result, a new vertex that correspond to *c*'s left endpoint is created and connected to *v* with a newly created halfedge pair. If *c* has an unbounded left end, the new vertex lies at infinity and the unbounded face that contains the interior of the curve is split. The function returns a handle for one of the new halfedges corresponding to the inserted curve, directed to the newly created vertex — that is, directed in lexicographic decreasing order (from right to left).

Precondition: The interior of *c* is disjoint from all existing arrangement vertices and edges.

Precondition: *v* is associated with the right endpoint of *c*.

Precondition: The left endpoint of *c* is not already associated with an existing arrangement vertex.

```
Halfedge_handle arr.insert_at_vertices( X_monotone_curve_2 c, Vertex_handle v1, Vertex_handle v2)
```

inserts the curve c into the arrangement, such that both c 's endpoints correspond to existing arrangement vertices, given by $v1$ and $v2$. The function creates a new halfedge pair that connects the two vertices, and returns a handle for the halfedge directed from $v1$ to $v2$.

Precondition: The interior of c is disjoint from all existing arrangement vertices and edges.

Precondition: c must not be an unbounded curve.

Precondition: $v1$ and $v2$ are associated with c 's endpoints.

Precondition: If $v1$ and $v2$ are already connected by an edge, this edge represents an x -monotone curve that is interior-disjoint from c).

- *advanced*

```
Halfedge_handle arr.insert_in_face_interior( X_monotone_curve_2 c,
                                             Halfedge_handle fict_pred1,
                                             Halfedge_handle fict_pred2 = Halfedge_handle())
```

inserts an unbounded curve c into the arrangement, such that c is entirely contained within a single unbounded face of the arrangement. *fict_pred1* specifies the fictitious halfedge that should contain the vertex at infinity that corresponds to the unbounded end of c . If both ends of c are unbounded, *fict_pred1* indicated the place for its left end and *fict_pred2* indicated a place for its right end. The function returns a handle for one of the new halfedges directed (lexicographically) from left to right.

Precondition: c is an unbounded curve disjoint from all existing arrangement vertices and edges.

Precondition: *fict.pred1* (and *fict.pred2*) are fictitious halfedges that contains the unbounded end(s) of *c*. If both halfedges are given they must be both incident to the same unbounded face.

```
Halfedge_handle arr.insert_from_left_vertex( X_monotone_curve_2 c, Halfedge_handle pred)
```

inserts the curve c into the arrangement, such that its left endpoint corresponds to a given arrangement vertex. This vertex is the target vertex of the halfedge $pred$, such that c is inserted to the circular list of halfedges around $pred \rightarrow target()$ right between $pred$ and its successor. The function returns a handle for one of the new halfedges directed (lexicographically) from left to right.

Precondition: The interior of c is disjoint from all existing arrangement vertices and edges.

Precondition: $pred \rightarrow target()$ is associated with the left endpoint of c , and c should be inserted after $pred$ in a clockwise order around this vertex.

Precondition: The right endpoint of c is not already associated with an existing arrangement vertex.

[illegible]

inserts an unbounded curve c into the arrangement, such that its left endpoint is bounded and corresponds to a given arrangement vertex. This vertex is the target vertex of the halfedge $pred$, such that c is inserted to the circular list of halfedges around $pred \rightarrow target()$ right between $pred$ and its successor. Similarly, $fict_pred$ specifies the fictitious halfedge that should contain the vertex at infinity that corresponds to the unbounded right end of c . The function returns a handle for one of the new halfedges directed (lexicographically) from left to right.

Precondition: The interior of c is disjoint from all existing arrangement vertices and edges. c must have a bounded left endpoint and an unbounded right end.

Precondition: $pred \rightarrow target()$ is associated with the left endpoint of c , and c should be inserted after $pred$ in a clockwise order around this vertex.

Precondition: $fict_pred$ is a fictitious halfedge that contains the unbounded right end of c .

```
Halfedge_handle arr.insert_from_right_vertex( X_monotone_curve_2 c, Halfedge_handle pred)
```

inserts the curve c into the arrangement, such that its right endpoint corresponds to a given arrangement vertex. This vertex is the target vertex of the halfedge $pred$, such that c is inserted to the circular list of halfedges around $pred \rightarrow target()$ right between $pred$ and its successor. The function returns a handle for one of the new halfedges directed (lexicographically) from right to left.

Precondition: The interior of c is disjoint from all existing arrangement vertices and edges.

Precondition: $pred \rightarrow target()$ is associated with the right endpoint of c , and c should be inserted after $pred$ in a clockwise order around this vertex.

Precondition: The left endpoint of c is not already associated with an existing arrangement vertex.

```
Halfedge_handle    arr.insert_from_right_vertex( X_monotone_curve_2 c,
```

inserts an unbounded curve c into the arrangement, such that its right endpoint is bounded and corresponds to a given arrangement vertex. This vertex is the target vertex of the halfedge $pred$, such that c is inserted to the circular list of halfedges around $pred \rightarrow target()$ right between $pred$ and its successor. Similarly, $fict_pred$ specifies the fictitious halfedge that should contain the vertex at infinity that corresponds to the unbounded left end of c . The function returns a handle for one of the new halfedges directed (lexicographically) from right to left.

Precondition: The interior of c is disjoint from all existing arrangement vertices and edges. c must have a bounded right endpoint and an unbounded left end.

Precondition: $pred \rightarrow target()$ is associated with the right endpoint of c , and c should be inserted after $pred$ in a clockwise order around this vertex.

Precondition: $fict_pred$ is a fictitious halfedge that contains the unbounded left end of c .

inserts the curve c into the arrangement, such that both c 's endpoints correspond to existing arrangement vertices, given by $predI \rightarrow target()$ and $v2$. The function creates a new halfedge pair that connects the two vertices (where the corresponding halfedge is inserted right between $predI$ and its successor around $predI$'s target vertex) and returns a handle for the halfedge directed from $predI \rightarrow target()$ to $v2$.

Precondition: The interior of c is disjoint from all existing arrangement vertices and edges.

Precondition: $predI \rightarrow target()$ and $v2$ are associated with c 's endpoints.

Precondition: If $predI \rightarrow target$ and $v2$ are already connected by an edge, this edge represents an x -monotone curve that is interior-disjoint from c).

2054

Halfedge_handle *pred2*)

inserts the curve c into the arrangement, such that both c 's endpoints correspond to existing arrangement vertices, given by $pred1 \rightarrow target()$ and $pred2 \rightarrow target()$. The function creates a new halfedge pair that connects the two vertices (with $pred1$ and $pred2$ indicate the exact place for these halfedges around the two target vertices) and returns a handle for the halfedge directed from $pred1 \rightarrow target()$ to $pred2 \rightarrow target()$.

Precondition: The interior of c is disjoint from all existing arrangement vertices and edges.

Precondition: $pred1 \rightarrow target()$ and $pred2 \rightarrow target()$ are associated with c 's endpoints.

Precondition: If $pred1 \rightarrow target$ and $pred2 \rightarrow target()$ are already connected by an edge, this edge represents an x -monotone curve that is interior-disjoint from c).

_____ *advanced* _____

- *Modifying Vertices and Edges:*

Vertex_handle *arr.modify_vertex(Vertex_handle v, Point_2 p)*

sets p to be the point associated with the vertex v . The function returns a handle for the modified vertex (same as v).

Precondition: v is not a vertex at infinity and p is geometrically equivalent to the point currently associated with v .

Face_handle *arr.remove_isolated_vertex(Vertex_handle v)*

removes the isolated vertex v from the arrangement. The function returns the face f that used to contain the isolated vertex.

Precondition: v is an isolated vertex (has no incident edges).

Halfedge_handle *arr.modify_edge(Halfedge_handle e, X_monotone_curve_2 c)*

sets c to be the x -monotone curve associated with the edge e . The function returns a handle for the modified edge (same as e).

Precondition: c is geometrically equivalent to the curve currently associated with e .

CGAL::Arr_accessor<Arrangement>

Definition

Arr_accessor<Arrangement> provides an access to some of the private *Arrangement* functions. Users may use these functions to achieve more efficient programs when they have the exact topological information required by the specialized functions.

It is however highly recommended to be very careful when using the accessor functions that modify the arrangement. As we have just mentioned, these functions have very specific requirement on their input on one hand, and perform no preconditions on the other hand, so providing incorrect topological input may invalidate the arrangement.

```
#include <CGAL/Arr_accessor.h>
```

Types

Arr_accessor<Arrangement>::Arrangement_2 the type of the associated arrangement.

```
typedef typename Arrangement_2::Point_2
```

```
Point_2;                    the point type.
```

```
typedef typename Arrangement_2::X_monotone_curve_2
```

```
X_monotone_curve_2;
```

the *x*-monotone curve type.

```
typedef typename Arrangement_2::Vertex_handle
```

```
Vertex_handle;
```

```
typedef typename Arrangement_2::Halfedge_handle
```

```
Halfedge_handle;
```

```
typedef typename Arrangement_2::Face_handle
```

```
Face_handle;
```

```
typedef typename Arrangement_2::Ccb_halfedge_circulator
```

```
Ccb_halfedge_circulator;
```

represents the boundary of a connected component (CCB).

Creation

```
Arr_accessor<Arrangement> acc( Arrangement_2& arr);
```

constructs an accessor attached to the given arrangement *arr*.

Accessing the notification functions

void *acc.notify_before_global_change()*

notifies the arrangement observer that a global change is going to take place (for the usage of the global functions that operate on arrangements).

void *acc.notify_after_global_change()*

notifies the arrangement observer that a global change has taken place (for the usage of the global functions that operate on arrangements).

— *advanced* —

Arrangement Predicates

Halfedge_handle *acc.locate_around_vertex(Vertex_handle v, X_monotone_curve_2 c)*

locates a place for the curve *c* around the vertex *v* and returns a halfedge whose target is *v*, where *c* should be inserted between this halfedge and the next halfedge around *v* in a clockwise order.

int *acc.halfedge_distance(Halfedge_const_handle e1, Halfedge_const_handle e2)*

counts the number of edges along the path from *e1* to *e2*. In case the two halfedges do not belong to the same connected component, the function returns (-1).

bool *acc.is_inside_new_face(Halfedge_handle pred1, Halfedge_handle pred2, X_monotone_curve_2 c)*

determines whether a new halfedge we are about to create, which is to be associated with the curve *c* and directed from *pred1->target()* to *pred2->target()*, lies on the inner CCB of the new face that will be created, introducing this new edge.
Precondition: *pred1->target()* and *pred2->target()* are associated with *c*'s endpoints.
Precondition: *pred1* and *pred2* belong to the same connected component, such that a new face is created by connecting *pred1->target()* and *pred2->target()*.

bool *acc.point_is_in(Point_2 p, Halfedge_const_handle he)*

determines whether a given point lies within the region bounded by a boundary of the connected component that *he* belongs to. Note that if the function returns *true*, then *p* is contained within *he->face()* (but not on its boundary), or inside one of the holes inside this face, or it may coincide with an isolated vertex in this face.

<i>Halfedge_handle</i>	<code>acc.insert_at_vertices_ex(X_monotone_curve_2 c, Halfedge_handle pred1, Halfedge_handle pred2, Comparison_result res, bool& new_face)</code> <p>inserts the curve <i>c</i> into the arrangement, such that both <i>c</i>'s endpoints correspond to existing arrangement vertices, given by <i>pred1</i>-><i>target()</i> and <i>pred2</i>-><i>target()</i>. <i>res</i> is the comparison result between these two end-vertices. The function creates a new halfedge pair that connects the two vertices (with <i>pred1</i> and <i>pred2</i> indicate the exact place for these halfedges around the two target vertices) and returns a handle for the halfedge directed from <i>pred1</i>-><i>target()</i> to <i>pred2</i>-><i>target()</i>. The output flag <i>new_face</i> indicates whether a new face has been created following the insertion of the new curve. <i>Precondition:</i> It is the user's responsibility that <i>pred1</i>-><i>target()</i> and <i>pred2</i>-><i>target()</i> are associated with <i>c</i>'s endpoints and that if a new face is created, then <i>is_inside_new_face</i> (<i>pred1</i>, <i>pred2</i>, <i>c</i>) is <i>true</i>.</p>
<i>void</i>	<code>acc.insert_isolated_vertex(Face_handle f, Vertex_handle v)</code> <p>inserts <i>v</i> as an isolated vertex inside <i>f</i>. <i>Precondition:</i> It is the user's responsibility that <i>v</i>-><i>point()</i> is contained in the interior of the given face.</p>
<i>void</i>	<code>acc.move_hole(Face_handle f1, Face_handle f2, Ccb_halfedge_circulator hole)</code> <p>moves the given hole from the interior of the face <i>f1</i> inside the face <i>f2</i>. <i>Precondition:</i> It is the user's responsibility that <i>hole</i> is currently contained in <i>f1</i> and should be moved to <i>f2</i>.</p>
<i>bool</i>	<code>acc.move_isolated_vertex(Face_handle f1, Face_handle f2, Vertex_handle v)</code> <p>moves the given isolated vertex from the interior of the face <i>f1</i> inside the face <i>f2</i>. <i>Precondition:</i> It is the user's responsibility that <i>v</i> is indeed an isolated vertex currently contained in <i>f1</i> and should be moved to <i>f2</i>.</p>
<i>void</i>	<code>acc.relocate_in_new_face(Halfedge_handle he)</code> <p>relocates all holes and isolated vertices to their proper position immediately after a face has split due to the insertion of a new halfedge, namely after <i>insert_at_vertices_ex()</i> was invoked and indicated that a new face has been created. <i>he</i> is the halfedge returned by <i>insert_at_vertices_ex()</i>, such that <i>he</i>-><i>twin()</i>-><i>face</i> is the face that has just been split and <i>he</i>-><i>face()</i> is the newly created face.</p>

<i>void</i>	<i>acc.relocate_holes_in_new_face(Halfedge_handle he)</i>	relocates all holes in a new face, as detailed above.
<i>void</i>	<i>acc.relocate_isolated_vertices_in_new_face(Halfedge_handle he)</i>	relocates all isolated vertices in a new face, as detailed above.
<i>Vertex_handle</i>	<i>acc.modify_vertex_ex(Vertex_handle v, Point_2 p)</i>	<p>modifies the point associated with the vertex v (the point may be geometrically different than the one currently associated with v). The function returns a handle to the modified vertex (same as v).</p> <p><i>Precondition:</i> It is the user's responsibility that no other arrangement vertex is already associated with p.</p>
<i>Halfedge_handle</i>	<i>acc.modify_edge_ex(Halfedge_handle e, X_monotone_curve_2 c)</i>	<p>modifies the x-monotone curve associated with the edge e (the curve c may be geometrically different than the one currently associated with e). The function returns a handle to the modified edge (same as e).</p> <p><i>Precondition:</i> It is the user's responsibility that the interior of c is disjoint from all existing arrangement vertices and edges.</p>
<i>Halfedge_handle</i>	<i>acc.split_edge_ex(Halfedge_handle he, Point_2 p, X_monotone_curve_2 c1, X_monotone_curve_2 c2)</i>	<p>splits a given edge into two at the split point p, and associate the x-monotone curves $c1$ and $c2$ with the resulting edges, such that $c1$ connects $he \rightarrow source()$ with p and $c2$ connects p with $he \rightarrow target()$. The function return a handle to the split halfedge directed from $he \rightarrow source()$ to the split point p.</p> <p><i>Precondition:</i> It is the user's responsibility that the endpoints of $c1$ and $c2$ correspond to p and to he's end-vertices, as indicated above.</p>
<i>Halfedge_handle</i>	<i>acc.split_edge_ex(Halfedge_handle he, Vertex_handle v, X_monotone_curve_2 c1, X_monotone_curve_2 c2)</i>	<p>splits a given edge into two at by the vertex v, and associate the x-monotone curves $c1$ and $c2$ with the resulting edges, such that $c1$ connects $he \rightarrow source()$ with v and $c2$ connects v with $he \rightarrow target()$. The function return a handle to the split halfedge directed from $he \rightarrow source()$ to v.</p> <p><i>Precondition:</i> It is the user's responsibility that the endpoints of $c1$ and $c2$ correspond to v and to he's end-vertices, as indicated above. It is also assumed that v has no incident edges.</p>

Face_handle

```
acc.remove_edge_ex( Halfedge_handle he,  
bool remove_source = true,  
bool remove_target = true)
```

removes the edge *he* from the arrangement, such that if the edge removal causes the creation of a new hole, *he->target()* lies on the boundary of this hole. The flags *remove_source* and *remove_target* indicate whether the end-vertices of *he* should be removed as well, in case they have no other incident edges. If the operation causes two faces to merge, the merged face is returned. Otherwise, the face to which the edge was incident is returned.

└────────── *advanced* ─────────┘

CGAL::Arrangement_2<Traits,Dcel>::Vertex

Definition

An object v of the class *Vertex* represents an arrangement vertex, that is — a 0-dimensional cell, associated with a point on the plane.

Inherits From

typename Dcel::Vertex

Creation

<i>Vertex</i> <i>v</i> ;	default constructor.
--------------------------	----------------------

Access Functions

All non-const methods listed below also have *const* counterparts that return constant handles, iterators or circulators:

<i>bool</i>	<i>v.is_at_open_boundary()</i>
	checks whether the vertex lies at infinity and not associated with a point with bounded coordinates.

<i>bool</i>	<i>v.is_isolated()</i>	checks whether the vertex is isolated (i.e., has no incident edges).
-------------	------------------------	--

<i>typename Dcel::Size</i>	<i>v.degree()</i>	returns the number of edges incident to <i>v</i> .
----------------------------	-------------------	--

Halfedge_around_vertex_circulator *v.incident_halfedges()*

returns a circulator circulator that allows going over the halfedges incident to *v* (that have *v* as their target). The edges are traversed in a clockwise direction around *v*.

Precondition: *v* is *not* an isolated vertex.

<i>Face_handle</i>	<i>v.face()</i>	returns a handle to the face that contains <i>v</i> in its interior. <i>Precondition:</i> <i>v</i> is an isolated vertex.
--------------------	-----------------	--

<i>typename Traits::Point_2</i>	<i>v.point()</i>	returns the point associated with the vertex.
		<i>Precondition:</i> <i>v</i> is not a vertex at infinity.

<i>Arr_parameter_space</i>	<i>v.parameter_space_in_x()</i>	
		returns the placement of the x -coordinate in the parameter space, that is, either the left boundary-side, the interior, or the right boundary-side.

Arr_parameter_space

v.parameter_space_in_y()

returns the placement of the y-coordinate in the parameter space, that is, either the bottom boundary-side, the interior, or the top boundary-side.

CGAL::Arrangement_2<Traits,Dcel>::Halfedge

Definition

An object e of the class *Halfedge* represents a halfedge in the arrangement. A halfedge is directed from its *source* vertex to its *target* vertex, and has an *incident face* lying to its right. Each halfedge has a *twin* halfedge directed in the opposite direction, where the pair of twin halfedges form together an arrangement edge, that is — a 1-dimensional cell, associated with planar x -monotone curve.

Halfedges are sorted in doubly-connected lists and form chains. These chains define the inner and outer boundaries of connected components.

Inherits From

typename Dcel::Halfedge

Creation

<i>Halfedge</i> <i>e</i> ;	default constructor.
----------------------------	----------------------

Access Functions

All non-const methods listed below also have *const* counterparts that return constant handles, iterators or circulators:

<i>bool</i>	<i>e.is_fictitious()</i>	returns whether the halfedge is fictitious (i.e., connects two vertices at infinity and is not associated with a valid curve).
<i>Vertex_handle</i>	<i>e.source()</i>	returns a handle for the source vertex of <i>e</i> .
<i>Vertex_handle</i>	<i>e.target()</i>	returns a handle for the target vertex of <i>e</i> .
<i>Arr_halfedge_direction</i>	<i>e.direction()</i>	returns the direction of the halfedge: <i>ARR_LEFT_TO_RIGHT</i> if <i>e</i> 's source vertex is lexicographically smaller than its target (so the halfedge is directed from left to right), and <i>ARR_RIGHT_TO_LEFT</i> if it is lexicographically larger than the target (so the halfedge is directed from right to left).
<i>Face_handle</i>	<i>e.face()</i>	returns the face that <i>e</i> is incident to (The face lies to the left of <i>e</i>).
<i>Halfedge_handle</i>	<i>e.twin()</i>	returns the twin halfedge.
<i>Halfedge_handle</i>	<i>e.prev()</i>	returns <i>e</i> 's predecessor in the connected component it belongs to.
<i>Halfedge_handle</i>	<i>e.next()</i>	returns <i>e</i> 's successor in the connected component it belongs to.

Ccb_halfedge_circulator *e.ccb()* returns a circulator that allows traversing the halfedges of the connected component boundary (CCB) that contains *e*. The circulator is initialized to point to *e*.

typename Traits::X_monotone_curve_2

e.curve() returns the *x*-monotone curve associated with *e*.
Precondition: *e* is not a fictitious halfedge.

CGAL::Arrangement_2<Traits,Dcel>::Face

Definition

An object e of the class *Face* represents an arrangement edge, namely a 2-dimensional arrangement cell. Every arrangement contains exactly one *unbounded* face, and a number of bounded face. Each bounded face has a boundary comprised of a halfedge chain winding in a counterclockwise orientation around it. A face may also contain holes, which are defined by clockwise-oriented halfedge chains, and isolated vertices.

Inherits From

typename Dcel::Face

Creation

<i>Face</i> <i>f</i> ;	default constructor.
------------------------	----------------------

Access Functions

All non-const methods listed below also have *const* counterparts that return constant handles, iterators or circulators:

<i>bool</i>	<i>f.is_fictitious()</i>	returns whether this is the fictitious face, which contain the entire arrangement (and has not outer CCB).
-------------	--------------------------	--

<i>bool</i>	<i>f.is_unbounded()</i>	returns whether the face is unbounded.
-------------	-------------------------	--

Ccb_halfedge_circulator

f.outer_ccb() returns a circulator that allows going over the outer boundary of *f*. The edges along the CCB are traversed in a counter-clockwise direction.
Precondition: *f* is not a fictitious face.

<i>Hole_iterator</i>	<i>f.holes_begin()</i>	returns an iterator for traversing all the holes (inner CCBs) of <i>f</i> .
----------------------	------------------------	---

<i>Hole_iterator</i>	<i>f.holes_end()</i>	returns a past-the-end iterator for the holes of <i>f</i> .
----------------------	----------------------	---

Isolated_vertex_iterator

f.isolated_vertices_begin()

returns an iterator for traversing all the isolated vertices contained in the interior of f .

Isolated_vertex_iterator

f.isolated_vertices_end()

returns a past-the-end iterator for the isolated vertices contained inside f .

CGAL::is_valid

Definition

The function *is_valid* checks the validity of a given arrangement.

```
#include <CGAL/Arrangement_2.h>
```

```
template<typename Traits, typename Dcel>  
bool          is_valid( Arrangement_2<Traits, Dcel> arr)
```

Invokes the member function *arr.is_valid()* to verify the topological correctness of the arrangement. Then it performs additional validity tests. It checks that all *x*-monotone curves associated with arrangement edges are pairwise disjoint in their interior. Then it makes sure that all holes and all isolated vertices are located within the proper arrangement faces. Note that the test carried out by this function may take a considerable amount of time; it is recommended to be used only for debugging purposes.

Requirements

The instantiated traits class must model the concept *ArrangementXMonotoneTraits_2*.

CGAL::insert

Definition

The function *insert* inserts one or more curves or *x*-monotone curves into a given arrangement, where no restrictions are imposed on the inserted curves. If an inserted curve is not *x*-monotone curve, it is subdivided into *x*-monotone subcurves (and perhaps isolated points), which are inserted into the arrangement.

```
#include <CGAL/Arrangement_2.h>
```

```
template<class Traits, class Dcel, class Curve, class PointLocation>
void insert( Arrangement_2<Traits,Dcel>& arr, Curve c, PointLocation pl = walk_pl)
```

Inserts the given curve *c* into the arrangement *arr*. *c* is subdivided into *x*-monotone subcurves (and perhaps isolated points). Each subcurve is in turn inserted into the arrangement by locating its left endpoint and computing its zone until reaching the right endpoint.

The given point-location object *pl* is used to locate the left endpoints of the *x*-monotone curves. By default, the function uses the “walk along line” point-location strategy — namely an instance of the class *Arr_walk_along_line_point_location*<Arrangement_2<Traits,Dcel> >.

Precondition: If provided, *pl* must be attached to the given arrangement *arr*.

```
template<typename Traits, typename Dcel>
void insert( Arrangement_2<Traits,Dcel>& arr,
             typename Traits::X_monotone_curve_2 xc,
             Object obj)
```

Inserts the *x-monotone (only)* curve *xc* into the arrangement *arr*. The object *obj*, which either wraps a *Vertex_const_handle*, a *Halfedge_const_handle*, or a *Face_const_handle*, represents the location of *xc*’s left endpoint in the arrangement. The zone of *xc* is computed strating from the feature represented by *obj*. As in the case above, the zone computation terminates, when the right endpoint is reached. Thus, point-location is not required.

```
template<class Traits, class Dcel, class InputIterator>
void insert( Arrangement_2<Traits,Dcel>& arr, InputIterator first, InputIterator last)
```

Aggregately inserts the curves or *x*-monotone curves in the range *[first,last)* into the arrangement *arr* using the sweep-line framework.

```
#include <CGAL/Arrangement_with_history_2.h>
```

```
template<typename Traits, typename Dcel, typename PointLocation>
typename Arrangement_with_history_2<Traits,Dcel>::Curve_handle
    insert( Arrangement_with_history_2<Traits,Dcel>& arr,
            typename Traits::Curve_2 c,
            PointLocation pl = walk_pl)
```

Inserts the given curve *c* into the arrangement with history *arr*, and returns a handle to the inserted curve. *c* is subdivided into *x*-monotone subcurves (and perhaps isolated points). Each subcurve is in turn inserted into the arrangement by locating its left endpoint and computing its zone until reaching the right endpoint.

The given point-location object *pl* is used to locate the left endpoints of the *x*-monotone curves. By default, the function uses the “walk along line” point-location strategy — namely an instance of the class *Arr_walk_along_line_point_location*<*Arrangement_2*<*Traits*,*Dcel*> >.

Precondition: If provided, *pl* is attached to the given arrangement *arr*.

```
template<class Traits, class Dcel, InputIterator>
void          insert( Arrangement_with_history_2<Traits,Dcel>& arr, InputIterator first, InputIterator last)
```

Aggregately inserts the curves in the range [*first,last*) into the arrangement with history *arr* using the sweep-line framework.

Requirements

- If the curve is *x*-monotone curve then The instantiated *Traits* class must model the *ArrangementXMonotoneTraits_2* concept. In case that the curve is not *x*-monotone then the instantiated *Traits* class must model the *ArrangementTraits_2* concept. That is, it should define the *Curve_2* type, and support its subdivision into *x*-monotone subcurves (and perhaps isolated points).
- The point-location object *pl*, must model the *ArrangementPointLocation_2* concept.

CGAL::insert_non_intersecting_curve

Definition

The function *insert_non_intersecting_curve* inserts a given x -monotone curve into a given arrangement, where the interior of the given curve is disjoint from all existing arrangement vertices and edges. Under this assumption, it is possible to locate the endpoints of the given curve in the arrangement, and use one of the specialized insertion member-functions of the arrangement according to the results. The insertion operation creates a single new edge, that is, two twin halfedges, and the function returns a handle for the one directed lexicographically in increasing order (from left to right).

A given point-location object is used for answering the two point-location queries on the given curve endpoints. By default, the function uses the “walk along line” point-location strategy — namely, an instance of the class *Arr_walk_along_line_point_location*<*Arrangement_2*<*Traits*,*Dcel*>>.

```
#include <CGAL/Arrangement_2.h>
```

```
template<typename Traits, typename Dcel, typename PointLocation>
typename Arrangement_2<Traits,Dcel>::Halfedge_handle
```

```
    insert_non_intersecting_curve( Arrangement_2<Traits,Dcel>& arr,
                                typename Traits::X_monotone_curve_2 xc,
                                PointLocation pl = walk_pl)
```

Precondition: If provided, *pl* must be attached to the given arrangement *arr*.

Requirements

- The instantiated *Traits* class must model the restricted *ArrangementBasicTraits_2* concept, as no intersections are computed.
- The point-location object *pl* must model the *ArrangementPointLocation_2* concept.

CGAL::insert_non_intersecting_curves

Definition

The function *insert_non_intersecting_curves* inserts a set of *x*-monotone curves in a given range into a given arrangement. The insertion is performed in an aggregated manner, using the sweep-line algorithm. The input curves should be pairwise disjoint in their interior and pairwise interior-disjoint from all existing arrangement vertices and edges.

```
#include <CGAL/Arrangement_2.h>
```

```
template<typename Traits, typename Dcel, InputIterator>  
void          insert_non_intersecting_curves( Arrangement_2<Traits,Dcel>& arr,  
                                              InputIterator first,  
                                              InputIterator last)
```

Requirements

- The instantiated *Traits* class must model the *ArrangementBasicTraits_2* concept, as no intersections are computed.
- *InputIterator::value_type* must be *Traits::X_monotone_curve_2*

CGAL::insert_point

Definition

The function *insert_point* inserts a given point into a given arrangement. It uses a given point-location object to locate the given point in the given arrangement. If the point coincides with an existing vertex, there is nothing left to do; if it lies on an edge, the edge is split at the point. Otherwise, the point is contained inside a face, and is inserted as an isolated vertex inside this face. By default, the function uses the “walk along line” point-location strategy — namely, an instance of the class *Arr_walk_along_line_point_location*<*Arrangement_2*<*Traits*,*Dcel*>>. In either case, the function returns a handle for the vertex associated with the point.

```
#include <CGAL/Arrangement_2.h>
```

```
template<typename Traits, typename Dcel, typename PointLocation>
typename Arrangement_2<Traits,Dcel>::Vertex_handle
```

```
    insert_point( Arrangement_2<Traits,Dcel>& arr,
                  typename Traits::Point_2 p,
                  PointLocation pl = walk_pl)
```

Precondition: If provided, *pl* must be attached to the given arrangement *arr*.

Requirements

- The instantiated *Traits* class must model the *ArrangementXMonotoneTraits_2* concept. Not all expressions listed by this concept are required. In fact the traits class must model the *ArrangementBasicTraits_2* concept, and support the splitting functionality.
- The point-location object *pl*, must model the *ArrangementPointLocation_2* concept.

CGAL::zone

Definition

The function *zone* compute the zone of the given *x*-monotone curve in the existing arrangement. Meaning, it output the arrangement's vertices, edges and faces that the *x*-monotone curve intersects. The order of the objects is the order that they are discovered when traversing the *x*-monotone curve from left to right.

A given point-location object is used for answering point-location queries during the insertion process. By default, the function uses the “walk along line” point-location strategy — namely an instance of the class *Arr_walk_along_line_point_location*<*Arrangement_2*<*Traits*,*Dcel*> >.

```
#include <CGAL/Arrangement_2.h>
```

```
template <class GeomTraits, class TopTraits, class OutputIterator, class PointLocation>
OutputIterator      zone( Arrangement_on_surface_2<GeomTraits, TopTraits>& arr,
                        typename GeomTraits::X_monotone_curve_2 c,
                        OutputIterator oi,
                        PointLocation pl)
```

Compute the zone of the given *x*-monotone curve *c* in the arrangement *arr*.

Precondition: If provided, *pl* must be attached to the given arrangement *arr*.

Requirements

- The instantiated *GeomTraits* class must model the *ArrangementXMonotoneTraits_2* concept.
- The point-location object *pl*, must model the *ArrangementPointLocation_2* concept.

CGAL::do_intersect

Definition

The function *do_intersect* checks if a given curve or *x*-monotone curve intersects an existing arrangement's edges or vertices.

If the given curve is not an *x*-monotone curve then the function subdivides the given curve into *x*-monotone subcurves and isolated vertices. Each subcurve is in turn checked for intersection. The function uses the zone algorithm to check if the curve intersects the arrangement. First, the curve's left endpoint is located. Then, its zone is computed starting from its left endpoint location. The zone computation terminates when an intersection with an arrangement's edge/vertex is found or when the right endpoint is reached.

A given point-location object is used for locating the left endpoint of the given curve in the existing arrangement. By default, the function uses the “walk along line” point-location strategy — namely an instance of the class *Arr_walk_along_line_point_location*<*Arrangement_2*<*Traits*,*Dcel*>>.

```
#include <CGAL/Arrangement_2.h>
```

```
template <class GeomTraits, class TopTraits, class Curve, class PointLocation>
bool do_intersect( Arrangement_on_surface_2<GeomTraits, TopTraits>& arr,
                  Curve c,
                  PointLocation pl)
```

Checks if the given curve or *x*-monotone curve *c* intersects edges or vertices of the existing arrangement *arr*.

Precondition: If provided, *pl* must be attached to the given arrangement *arr*.

Requirements

- If *c* is *x*-monotone then the instantiated *GeomTraits* class must model the *ArrangementXMonotoneTraits_2* concept. If *c* is a curve then the instantiated *GeomTraits* class must model the *ArrangementTraits_2* concept. That is, it should define the *Curve_2* type, and support its subdivision into *x*-monotone subcurves (and perhaps isolated points).
- The point-location object *pl*, must model the *ArrangementPointLocation_2* concept.

CGAL::remove_edge

Definition

The function *remove_edge* removes an edge given by one of the twin halfedges that forms it, from a given arrangement. Once the edge is removed, if the vertices associated with its endpoints become isolated, they are removed as well. The call *remove_edge(arr, e)* is equivalent to the call *arr.remove_edge(e, true, true)*. However, this free function requires that *Traits* be a model of the refined concept *ArrangementXMonotoneTraits_2*, which requires merge operations on *x*-monotone curves. If one of the end-vertices of the given edge becomes redundant after the edge is removed (see *remove_vertex()* for the definition of a redundant vertex), it is removed, and its incident edges are merged. If the edge-removal operation causes two faces to merge, the merged face is returned. Otherwise, the face to which the edge was incident before the removal is returned.

```
#include <CGAL/Arrangement_2.h>
```

```
template<typename Traits, typename Dcel>
typename Arrangement_2<Traits,Dcel>::Face_handle
```

```
remove_edge( Arrangement_2<Traits,Dcel>& arr,
             typename Arrangement_2<Traits,Dcel>::Halfedge_handle e)
```

Requirements

- The instantiated traits class must model the concept *ArrangementXMonotoneTraits_2*.

CGAL::remove_vertex

Definition

The function *remove_vertex* attempts to removed a given vertex from a given arrangement. The vertex can be removed if it is either an isolated vertex, (and has no incident edge,) or if it is a *redundant* vertex. That is, it has exactly two incident edges, whose associated curves can be merged to form a single *x*-monotone curve. The function returns a boolean value that indicates whether it succeeded removing the vertex from the arrangement.

```
#include <CGAL/Arrangement_2.h>
```

```
template <typename Traits, typename Dcel>
bool      remove_vertex( Arrangement_2<Traits,Dcel>& arr,
                        typename Arrangement_2<Traits,Dcel>::Vertex_handle v)
```

Requirements

- The instantiated *Traits* class must model the *ArrangementXMonotoneTraits_2* concept. Not all expressions listed by this concept are required. In fact the traits class must model the *ArrangementBasicTraits_2* concept and support the merging functionality.

CGAL::overlay

Definition

The function *overlay* computes the overlay of two input arrangement objects, and returns the overlaid arrangement. All three arrangements can be instantiated with different geometric traits classes and different DCEL (encapsulated in the various topology-traits classes) classes. The geometry traits of the resulting arrangement is used to construct the resulting arrangement. This means that all the types (e.g., *Traits::Point_2*, *Traits::Curve_2*, and *Traits::Point_2*) of both input arrangements have to be convertible to the types in the resulting arrangement. A given overlay-traits object is used to properly construct the overlaid DCEL that represents the resulting arrangement.

```
#include <CGAL/Arr_overlay_2.h>
```

```
template <class GeomTraitsA, class GeomTraitsB, class GeomTraitsRes, class TopTraitsA, class TopTraitsB,
class TopTraitsRes, class OverlayTraits>
void overlay( Arrangement_2<GeomTraitsA, TopTraitsA> arr1,
              Arrangement_2<GeomTraitsB, TopTraitsB> arr2,
              Arrangement_2<GeomTraitsRes, TopTraitsRes>& arr_res,
              OverlayTraits& ovl_tr)
```

Computes the overlay of two arrangements *arr1* and *arr2*, and sets the output arrangement *res* to represent the overlaid arrangement.

Precondition: *res* does not refer to either *arr1* or *arr2* (that is, “self overlay” is not supported).

```
template <class GeomTraitsA, class GeomTraitsB, class GeomTraitsRes, class TopTraitsA, class TopTraitsB,
class TopTraitsRes>
void overlay( Arrangement_2<GeomTraitsA, TopTraitsA> arr1,
              Arrangement_2<GeomTraitsB, TopTraitsB> arr2,
              Arrangement_2<GeomTraitsRes, TopTraitsRes>& arr_res)
```

Computes the (simple) overlay of two arrangements *arr1* and *arr2*, and sets the output arrangement *res* to represent the overlaid arrangement. It employs the default overlay-traits, which practically does nothing.

Precondition: *res* does not refer to either *arr1* or *arr2* (that is, “self overlay” is not supported).

```
#include <CGAL/Arrangement_with_history_2.h>
```

```
template<typename Traits, typename Dcel1, typename Dcel2, typename ResDcel, typename OverlayTraits>
void overlay( Arrangement_with_history_2<Traits,Dcel1> arr1,
              Arrangement_with_history_2<Traits,Dcel2> arr2,
              Arrangement_with_history_2<Traits,ResDcel>& res,
              OverlayTraits& ovl_tr)
```

Computes the overlay of two arrangements with history *arr1* and *arr2*, and sets the output arrangement with history *res* to represent the overlaid arrangement. The function also constructs a consolidated set of curves that induce *res*.

Precondition: *res* does not refer to either *arr1* or *arr2* (that is, “self overlay” is not supported).

```
template<typename Traits, typename Dcell1, typename Dcel2, typename ResDcel>
void      overlay( Arrangement_with_history_2<Traits,Dcell1> arr1,
                  Arrangement_with_history_2<Traits,Dcel2> arr2,
                  Arrangement_with_history_2<Traits,ResDcel>& res)
```

Computes the (simple) overlay of two arrangements with history *arr1* and *arr2*, and sets the output arrangement with history *res* to represent the overlaid arrangement. The function also constructs a consolidated set of curves that induce *res*. It employs the default overlay-traits, which practically does nothing.

Precondition: *res* does not refer to either *arr1* or *arr2* (that is, “self overlay” is not supported).

Requirements

- The overlay-traits object *ovl_tr* must model the *OverlayTraits* concept, which is able to construct records of the *ResDcel* class on the basis of the *Dcell1* and *Dcel2* records that induce them.

See Also

OverlayTraits(page [2081](#))

OverlayTraits

A model for the OverlayTraits should be able to operate on records (namely, vertices, halfedges and faces) of two input DCEL classes, named *Dcel_A* and *Dcel_B*, and construct the records of an output DCEL class, referred to as *Dcel_R*.

Models for the concept are used by the global *overlay()* function to maintain the auxiliary data stored with the DCEL records of the resulting overlaid arrangement, based on the contents of the input records.

Types

<i>OverlayTraits:: Vertex_handle_A</i>	a constant handle a vertex in <i>Dcel_A</i> .
<i>OverlayTraits:: Halfedge_handle_A</i>	a constant handle to a halfedge in <i>Dcel_A</i> .
<i>OverlayTraits:: Face_handle_A</i>	a constant handle to a face <i>Dcel_A</i> .
<i>OverlayTraits:: Vertex_handle_B</i>	a constant handle to a vertex in <i>Dcel_B</i> .
<i>OverlayTraits:: Halfedge_handle_B</i>	a constant handle to a halfedge in <i>Dcel_B</i> .
<i>OverlayTraits:: Face_handle_B</i>	a constant handle to a face in <i>Dcel_B</i> .
<i>OverlayTraits:: Vertex_handle_R</i>	a handle to a vertex in <i>Dcel_R</i> .
<i>OverlayTraits:: Halfedge_handle_R</i>	a handle to a halfedge in <i>Dcel_R</i> .
<i>OverlayTraits:: Face_handle_R</i>	a handle to a faces in <i>Dcel_R</i> .

Functions

Whenever a vertex in the overlaid arrangement is created, one of the following functions is called in order to attach the appropriate auxiliary data to this vertex:

<i>void</i>	<i>ovl_tr.create_vertex(Vertex_handle_A v1, Vertex_handle_B v2, Vertex_handle_R v)</i>	constructs the vertex <i>v</i> induced by the coinciding vertices <i>v1</i> and <i>v2</i> .
<i>void</i>	<i>ovl_tr.create_vertex(Vertex_handle_A v1, Halfedge_handle_B e2, Vertex_handle_R v)</i>	constructs the vertex <i>v</i> induced by the vertex <i>v1</i> that lies on the halfedge <i>e2</i> .
<i>void</i>	<i>ovl_tr.create_vertex(Vertex_handle_A v1, Face_handle_B f2, Vertex_handle_R v)</i>	constructs the vertex <i>v</i> induced by the vertex <i>v1</i> that lies inside the face <i>f2</i> .
<i>void</i>	<i>ovl_tr.create_vertex(Halfedge_handle_A e1, Vertex_handle_B v2, Vertex_handle_R v)</i>	constructs the vertex <i>v</i> induced by the vertex <i>v2</i> that lies on the halfedge <i>e1</i> .

void *ovl_tr.create_vertex(Face_handle_A f1, Vertex_handle_B v2, Vertex_handle_R v)*

constructs the vertex v induced by the vertex $v2$ that lies inside the face $f1$.

void *ovl_tr.create_vertex(Halfedge_handle_A e1, Halfedge_handle_B e2, Vertex_handle_R v)*

constructs the vertex v induced by the intersection of the halfedges $e1$ and $e2$.

Whenever an edge in the overlaid arrangement is created, one of the following functions is called in order to attach the appropriate auxiliary data to this vertex. Note that an edge is created after both its end-vertices are created, (and the corresponding *create_vertex()* methods were invoked). In all cases, the edge is represented by a halfedge e directed in lexicographic decreasing order (from right to left). The *create_edge()* method should attach auxiliary data to the twin halfedge (namely to $e \rightarrow \text{twin}()$) as well:

void *ovl_tr.create_edge(Halfedge_handle_A e1, Halfedge_handle_B e2, Halfedge_handle_R e)*

constructs the halfedge e induced by an overlap between the halfedges $e1$ and $e2$.

void *ovl_tr.create_edge(Halfedge_handle_A e1, Face_handle_B f2, Halfedge_handle_R e)*

constructs the halfedge e induced by the halfedge $e1$ that lies inside the face $f2$.

void *ovl_tr.create_edge(Face_handle_A f1, Halfedge_handle_B e2, Halfedge_handle_R e)*

constructs the halfedge e induced by the halfedge $e2$ that lies inside the face $f1$.

The following function is invoked whenever a new face is created. It is guaranteed that all halfedges along the face boundary have already been created and have their auxiliary data fields attached to them:

void *ovl_tr.create_face(Face_handle_A f1, Face_handle_B f2, Face_handle_R f)*

constructs the face f induced by the an overlap between the faces $f1$ and $f2$.

Has Models

Arr_face_overlay_traits<Arr1, Arr2, ResArr, OvlFaceData> (page [2084](#))

See Also

overlay (page [2079](#))

CGAL::Arr_default_overlay_traits<Arrangement>

Definition

An instance of *Arr_default_overlay_traits*<*Arrangement*> should be used for overlaying two arrangements of type *Arrangement* that store no auxiliary data with their DCEL records, where the resulting overlaid arrangement stores no auxiliary DCEL data as well. This class simply gives empty implementation for all traits-class functions.

```
#include <CGAL/Arr_default_overlay_traits.h>
```

Is Model for the Concepts

OverlayTraits

See Also

overlay (page [2079](#))

CGAL::Arr_face_overlay_traits<Arr_A,Arr_B,Arr_R,OvlFaceData>

Definition

An instance of *Arr_face_overlay_traits*<Arr_A,Arr_B,Arr_R,OvlFaceData> should be used for overlaying two arrangements of types Arr_A and Arr_B, which are instantiated using the same geometric traits-class and with the DCEL classes *Dcel_A* and *Dcel_B* respectively, in order to store their overlay in an arrangement of type Arr_R, which is instantiated using a third DCEL class *Dcel_R*. All three DCEL classes are assumed to be instantiations of the *Arr_face_extended_dcel* template with types *FaceData_A*, *FaceData_B* and *FaceData_R*, respectively.

This class gives empty implementation for all overlay traits-class functions, except the function that computes the overlay of two faces. In this case, it uses the functor *OvlFaceData*, which accepts a *FaceData_A* object and a *FaceData_B* object and computes a corresponding *FaceData_R* object, in order to set the auxiliary data of the overlay face.

```
#include <CGAL/Arr_default_overlay_traits.h>
```

CGAL::read

Definition

The function *read* reads a given arrangement from a given input stream using a specific input format.

```
#include <CGAL/IO/Arr_istream.h>
```

```
template<typename Traits, typename Dcel, typename Formatter>
std::istream& read( Arrangement_2<Traits,Dcel>& arr, std::istream& is, Formatter& formatter)
```

Reads the arrangement object *arr* from the given input stream *is* using a specific input format defined by *formatter*.

```
#include <CGAL/IO/Arr_with_history_istream.h>
```

```
template<typename Traits, typename Dcel, typename WithHistoryFormatter>
std::istream& read( Arrangement_with_history_2<Traits,Dcel>& arr,
                  std::istream& is,
                  WithHistoryFormatter& formatter)
```

Reads the arrangement-with-history object *arr* from the given input stream *is* using a specific input format defined by *formatter*.

Requirements

- The instantiated *Formatter* class must model the *ArrangementInputFormatter* concept.
- The instantiated *WithHistoryFormatter* class must model the *ArrangementWithHistoryInputFormatter* concept.

ArrangementDcel

Definition

A doubly-connected edge-list (DCEL for short) data-structure. It consists of three containers of records: vertices V , halfedges E , and faces F . It maintains the incidence relation among them. The halfedges are ordered in pairs sometimes referred to as twins, such that each halfedge pair represent an edge.

A model of the ArrangementDcel concept must provide the following types and operations. (In addition to the requirements here, the local types *Vertex*, *Halfedge*, *Face*, *Hole* and *Isolated_vertex* must be models of the concepts *ArrangementDcelVertex*(page 2093), *ArrangementDcelHalfedge*(page 2095), *ArrangementDcelFace*(page 2098), *ArrangementDcelHole*(page 2100), and *ArrangementDcelIsolatedVertex* (page 2101) respectively.)

Types

<i>ArrangementDcel:: Vertex</i>	the vertex type.
<i>ArrangementDcel:: Halfedge</i>	the halfedge type.
<i>ArrangementDcel:: Face</i>	the face type.
<i>ArrangementDcel:: Hole</i>	the hole type.
<i>ArrangementDcel:: Isolated_vertex</i>	the isolated vertex type.
<i>ArrangementDcel:: Size</i>	used to represent size values (e.g., <i>size_t</i>).
<i>ArrangementDcel:: Vertex_iterator</i>	a bidirectional iterator over the vertices. Its value-type is <i>Vertex</i> .
<i>ArrangementDcel:: Halfedge_iterator</i>	a bidirectional iterator over the halfedges. Its value-type is <i>Halfedge</i> .
<i>ArrangementDcel:: Face_iterator</i>	a bidirectional iterator over the faces. Its value-type is <i>Face</i> .

The non-mutable iterators *Vertex_const_iterator*, *Halfedge_const_iterator* and *Face_const_iterator* are also defined.

Creation

<i>ArrangementDcel dcel;</i>	constructs an empty DCEL with one unbounded face.
<i>Face*</i>	<i>dcel.assign(Self other, const Face *uf)</i>
	assigns the contents of the <i>other</i> DCEL whose unbounded face is given by <i>uf</i> , to <i>dcel</i> . The function returns a pointer to the unbounded face of <i>dcel</i> after the assignment.

Access Functions

<i>Size</i>	<i>dcel.size_of_vertices()</i>	returns the number of vertices.
-------------	--------------------------------	---------------------------------

<i>Size</i>	<i>dcel.size_of_halfedges()</i>	returns the number of halfedges (always even).
<i>Size</i>	<i>dcel.size_of_faces()</i>	returns the number of faces.
<i>Size</i>	<i>dcel.size_of_holes()</i>	returns the number of holes (the number of connected components).
<i>Size</i>	<i>dcel.size_of_isolated_vertices()</i>	returns the number of isolated vertices.

The following operations have an equivalent *const* operations that return the corresponding non-mutable iterators:

<i>Vertex_iterator</i>	<i>dcel.vertices_begin()</i>	returns a begin-iterator of the vertices in <i>dcel</i> .
<i>Vertex_iterator</i>	<i>dcel.vertices_end()</i>	returns a past-the-end iterator of the vertices in <i>dcel</i> .
<i>Halfedge_iterator</i>	<i>dcel.halfedges_begin()</i>	returns a begin-iterator of the halfedges in <i>dcel</i> .
<i>Halfedge_iterator</i>	<i>dcel.halfedges_end()</i>	returns a past-the-end iterator of the halfedges in <i>dcel</i> .
<i>Face_iterator</i>	<i>dcel.faces_begin()</i>	returns a begin-iterator of the faces in <i>dcel</i> .
<i>Face_iterator</i>	<i>dcel.faces_end()</i>	returns a past-the-end iterator of the faces in <i>dcel</i> .

Modifiers

The following operations allocate a new element of the respective type. Halfedges are always allocated in pairs of opposite halfedges. The halfedges and their opposite pointers are automatically set.

<i>Vertex*</i>	<i>dcel.new_vertex()</i>	creates a new vertex.
<i>Halfedge*</i>	<i>dcel.new_edge()</i>	creates a new pair of twin halfedges.
<i>Face*</i>	<i>dcel.new_face()</i>	creates a new face.
<i>Hole*</i>	<i>dcel.new_hole()</i>	creates a new hole record.
<i>Isolated_vertex*</i>	<i>dcel.new_isolated_vertex()</i>	creates a new isolated vertex record.
<i>void</i>	<i>dcel.delete_vertex(Vertex* v)</i>	deletes the vertex <i>v</i> .
<i>void</i>	<i>dcel.delete_edge(Halfedge* e)</i>	deletes the halfedge <i>e</i> as well as its twin.
<i>void</i>	<i>dcel.delete_face(Face* f)</i>	deletes the face <i>f</i> .
<i>void</i>	<i>dcel.delete_hole(Hole* ho)</i>	deletes the hole <i>ho</i> .

void *dcel.delete_isolated_vertex(Isolated_vertex* iv)*
deletes the isolated vertex *iv*.

ArrangementDcelWithRebind

Definition

The concept `ArrangementDcelWithRebind` refines the *ArrangementDcel* concept by adding a policy clone idiom in form of a rebind struct-template.

Instantiate a dcel class with many different possible types without ad-hoc limitations on type of the dcel classes.

Refines

ArrangementDcel

Types

ArrangementDcelWithRebind::template <class T> rebind

allows the instantiation of a model of the base concept *ArrangementDcel* with a different possible geometry-traits classe without ad-hoc limitations on it.

Following the standard clone policy, the rebind struct-template must have a nested type named *other* that defines the type of the model replica.

Creation

ArrangementDcelWithRebind dcel; constructs an empty DCEL with one unbounded face.

Has Models

Arr_default_dcel<Traits> (page [2104](#))

Arr_face_extended_dcel<Traits,FData,V,H,F> (page [2105](#))

Arr_extended_dcel<Traits,VData,HData,FData,V,H,F> (page [2106](#))

ArrangementDcelVertex

Definition

A vertex record in a DCEL data structure. A vertex is always associated with a point. However, the vertex record only stores a pointer to the associated point, and the actual *Point* object is stored elsewhere.

A vertex usually has several halfedges incident to it, such that it is possible to access one of these halfedges directly and to traverse all incident halfedges around the vertex. However, the DCEL may also contain isolated vertices that have no incident halfedges. In this case, the vertex stores an isolated vertex-information record, indicating the face that contains this vertex in its interior.

Types

<i>ArrangementDcelVertex:: Halfedge</i>	the corresponding DCEL halfedge type.
<i>ArrangementDcelVertex:: Isolated_vertex</i>	the corresponding DCEL isolated vertex-information type.
<i>ArrangementDcelVertex:: Point</i>	the point type associated with the vertex.

Creation

<i>ArrangementDcelVertex v;</i>	default constructor.
<i>void v.assign(Self other)</i>	assigns <i>v</i> with the contents of the <i>other</i> vertex.

Access Functions

All functions below also have *const* counterparts, returning non-mutable pointers or references:

<i>bool v.is_isolated()</i>	returns whether the vertex is isolated (has no incident halfedges).
<i>Halfedge* v.halfedge()</i>	returns an incident halfedge that has <i>v</i> as its target. <i>Precondition:</i> <i>v</i> is <i>not</i> an isolated vertex.
<i>Isolated_vertex* v.isolated_vertex()</i>	returns the isolated vertex-information record. <i>Precondition:</i> <i>v</i> is an isolated vertex.
<i>bool v.has_null_point()</i>	returns whether the vertex is not associated with a valid point (i.e. it lies at infinity).
<i>Point& v.point()</i>	returns the associated point. <i>Precondition:</i> <i>v()</i> is associated with a valid point.

Arr_parameter_space

v.parameter_space_in_x()

returns the placement of the x -coordinate in the parameter space, that is, either the left boundary-side, the interior, or the right boundary-side.

Arr_parameter_space

v.parameter_space_in_y()

returns the placement of the y -coordinate in the parameter space, that is, either the bottom boundary-side, the interior, or the top boundary-side.

Modifiers

void

v.set_halfedge(Halfedge e)*

sets the incident halfedge, marking v as a regular vertex.

void

v.set_isolated_vertex(Isolated_vertex iv)*

sets the isolated vertex-information record, marking v as an isolated vertex.

void

v.set_point(Point p)* sets the associated point.

void

v.set_boundary(Arr_parameter_space inf_x, Arr_parameter_space inf_y)

sets v as a vertex on a boundary side.

Precondition: Either *inf_x* or *inf_y* is not *ARR_INTERIOR*.

ArrangementDcelHalfedge (page [2095](#))

ArrangementDcellIsolatedVertex (page [2101](#))

ArrangementDcelHalfedge

Definition

A halfedge record in a DCEL data structure. Two halfedges with opposite directions always form an edge (a halfedge pair). The halfedges form together chains, defining the boundaries of connected components, such that all halfedges along a chain have the same incident face. Note that the chain the halfedge belongs to may form the outer boundary of a bounded face (an outer CCB) or the boundary of a hole inside a face (an inner CCB).

An edge is always associated with a curve, but the halfedge records only store a pointer to the associated curve, and the actual curve objects are stored elsewhere. Two opposite halfedges are always associated with the same curve.

Types

<i>ArrangementDcelHalfedge::Vertex</i>	the corresponding DCEL vertex type.
<i>ArrangementDcelHalfedge::Face</i>	the corresponding DCEL face type.
<i>ArrangementDcelHalfedge::Hole</i>	the corresponding DCEL hole type.

<i>ArrangementDcelHalfedge::X_monotone_curve</i>	the curve type associated with the edge.
--	--

Creation

<i>ArrangementDcelHalfedge e;</i>	default constructor.
<i>void e.assign(Self other)</i>	assigns <i>e</i> with the contents of the <i>other</i> halfedge.

Access Functions

<i>Arr_halfedge_direction</i>	
<i>e.direction()</i>	returns <i>ARR_LEFT_TO_RIGHT</i> if <i>e</i> 's source vertex is lexicographically smaller than its target, and <i>ARR_RIGHT_TO_LEFT</i> if it is lexicographically larger than the target.
<i>bool e.is_on_hole()</i>	determines whether the <i>e</i> lies on an outer CCB of a bounded face, or on an inner CCB (a hole inside a face). The function returns <i>true</i> if <i>e</i> lies on a hole.

All functions below also have *const* counterparts, returning non-mutable pointers or references:

<i>Halfedge*</i>	<i>e.opposite()</i>	returns the twin halfedge.
<i>Halfedge*</i>	<i>e.prev()</i>	returns the previous halfedge along the chain.

<i>Halfedge*</i>	<i>e.next()</i>	returns the next halfedge along the chain.
<i>Vertex*</i>	<i>e.vertex()</i>	returns the target vertex.
<i>Face*</i>	<i>e.face()</i>	returns the incident face. <i>Precondition:</i> <i>e</i> lies on the outer boundary of this face.
<i>Hole*</i>	<i>e.hole()</i>	returns the hole (inner CCB) <i>e</i> belongs to. <i>Precondition:</i> <i>e</i> lies on a hole inside its incident face.
<i>bool</i>	<i>e.has_null_curve()</i>	returns whether the vertex is not associated with a valid curve.
<i>X_monotone_curve&</i>	<i>e.curve()</i>	returns the associated curve. <i>Precondition:</i> <i>e</i> is associated with a valid curve.

Modifiers

<i>void</i>	<i>e.set_opposite(Halfedge* opp)</i>	sets the opposite halfedge.
<i>void</i>	<i>e.set_direction(Arr_halfedge_direction dir)</i>	sets the lexicographical order between <i>e</i> 's source and target vertices to be <i>dir</i> . The direction of the opposite halfedge is also set to the opposite direction.
<i>void</i>	<i>e.set_prev(Halfedge* prev)</i>	sets the previous halfedge of <i>e</i> along the chain, and updates the cross-pointer <i>prev->next()</i> .
<i>void</i>	<i>e.set_next(Halfedge* next)</i>	sets the next halfedge of <i>e</i> along the chain, and updates the cross-pointer <i>next->prev()</i> .
<i>void</i>	<i>e.set_vertex(Vertex* v)</i>	sets the target vertex.
<i>void</i>	<i>e.set_face(Face* f)</i>	sets the incident face, marking that <i>e</i> lies on the outer CCB of the face <i>f</i> .
<i>void</i>	<i>e.set_hole(Hole* ho)</i>	sets the incident hole, marking that <i>e</i> lies on an inner CCB.

void *e.set_curve(X_monotone_curve* c)*

sets the associated curve of *e* and its opposite halfedge.

ArrangementDcelFace

Definition

A face record in a DCEL data structure. A face may either be unbounded, otherwise it has an incident halfedge along the chain defining its outer boundary. A face may also contain holes and isolated vertices in its interior.

Types

<i>ArrangementDcelFace:: Vertex</i>	the corresponding DCEL vertex type.
<i>ArrangementDcelFace:: Halfedge</i>	the corresponding DCEL halfedge type.
<i>ArrangementDcelFace:: Hole_iterator</i>	a bidirectional iterator over the holes in inside the face. Its value-type is <i>Halfedge*</i> .
<i>ArrangementDcelFace:: Isolated_vertex_iterator</i>	a bidirectional iterator over the isolated vertices in inside the face. Its value-type is <i>Vertex*</i> .

The non-mutable iterators *Hole_const_iterator*, and *Isolated_vertex_const_iterator* are also defined.

Creation

<i>ArrangementDcelFace f</i> ;	default constructor.
<i>void</i> <i>f.assign(Self other)</i>	assigns <i>f</i> with the contents of the <i>other</i> face.

Access Functions

All functions below also have *const* counterparts, returning non-mutable pointers or iterators:

<i>bool</i>	<i>f.is_unbounded()</i>	returns whether the face is unbounded.
<i>Halfedge*</i>	<i>f.halfedge()</i>	returns an incident halfedge along the outer boundary of the face. If <i>f</i> has no outer boundary, the function returns <i>NULL</i> .
<i>size_t</i>	<i>f.number_of_holes()</i>	returns the number of holes inside <i>f</i> .
<i>Hole_iterator</i>	<i>f.holes_begin()</i>	returns a begin-iterator for the holes inside <i>f</i> .
<i>Hole_iterator</i>	<i>f.holes_end()</i>	returns a past-the-end iterator for the holes inside <i>f</i> .
<i>size_t</i>	<i>f.number_of_isolated_vertices()</i>	returns the number of isolated vertices inside <i>f</i> .

Isolated_vertex_iterator

f.isolated_vertices_begin()

returns a begin-iterator for the isolated vertices inside *f*.

Isolated_vertex_iterator

f.isolated_vertices_end()

returns a past-the-end iterator for the isolated vertices inside *f*.

Modifiers

void

f.set_unbounded(bool flag)

sets the face as unbounded (if *flag* is *true*), or as a bounded face (if it is *false*).

void

f.set_halfedge(Halfedge e)*

sets the incident halfedge.

void

f.add_hole(Halfedge e)*

adds *e* as a hole inside *f*.

void

f.erase_hole(Hole_iterator it)

removes the hole that *it* points to from inside *f*.

void

f.add_isolated_vertex(Vertex v)*

adds *v* as an isolated vertex inside *f*.

void

f.erase_isolated_vertex(Isolated_vertex_iterator it)

removes the isolated vertex that *it* points to from inside *f*.

ArrangementDcelHole

Definition

A hole record in a DCEL data structure, which stores the face that contains the hole in its interior, along with an iterator for the hole in the holes' container of this face.

Types

ArrangementDcelHole::Face the corresponding DCEL face type.

typedef Face::Hole_iterator

Hole_iterator;

Creation

ArrangementDcelHole ho; default constructor.

Access Functions

All functions below also have *const* counterparts, returning non-mutable pointers or iterators:

*Face** *ho.face()* returns the incident face, which contains *ho* in its interior.

Hole_iterator *ho.iterator()* returns an iterator for the hole.

Modifiers

void *ho.set_face(Face* f)* sets the incident face.

void *ho.set_iterator(Hole_iterator it)*
sets the hole iterator.

ArrangementDcellIsolatedVertex

Definition

An isolated vertex-information record in a DCEL data structure, which stores the face that contains the isolated vertex in its interior, along with an iterator for the isolated vertex in the isolated vertices' container of this face.

Types

ArrangementDcellIsolatedVertex::Face the corresponding DCEL face type.

```
typedef Face::Isolated_vertex_iterator
        Isolated_vertex_iterator;
```

Creation

ArrangementDcellIsolatedVertex iv; default constructor.

Access Functions

All functions below also have *const* counterparts, returning non-mutable pointers or iterators:

*Face** *iv.face()* returns the incident face, which contains *iv* in its interior.

Isolated_vertex_iterator
 iv.iterator() returns an iterator for the isolated vertex.

Modifiers

void *iv.set_face(Face* f)* sets the incident face.

void *iv.set_iterator(Isolated_vertex_iterator it)*
 sets the isolated vertex iterator.

CGAL::Arr_dcel_base<V,H,F>

Definition

The *Arr_dcel_base*<*V,H,F*> class is an important ingredient in the definition of DCEL data structures. It serves as a basis class for any instance of the *Dcel* template parameter of the *Arrangement_2* template. In particular it is the basis class of the default *Dcel* template parameter, and the basis class of any extended DCEL. The template parameters *V*, *H*, and *F* must be instantiated with models of the concepts *ArrangementDcelVertex*, *ArrangementDcelHalfedge*, and *ArrangementDcelFace* respectively.

```
#include <CGAL/Arr_dcel_base.h>
```

Is Model for the Concepts

ArrangementDcel

Class Arr_vertex_base<Point>

Definition

The basic DCEL vertex type. Serves as a basis class for an extended vertex record with auxiliary data fields. The *Point* parameter is the type of points associated with the vertices.

Is Model for the Concepts

ArrangementDcelVertex

Class Arr_halfedge_base<Curve>

Definition

The basic DCEL halfedge type. Serves as a basis class for an extended halfedge record with auxiliary data fields. The *Curve* parameter is the type of *x*-monotone curves associated with the vertices.

ArrangementDcelHalfedge

Class Arr_face_base

Definition

The basic DCEL face type. Serves as a basis class for an extended face record with auxiliary data fields.

Is Model for the Concepts

ArrangementDcelFace

CGAL::Arr_default_dcel<Traits>

Definition

The default DCEL class used by the *Arrangement_2* class-template is parameterized by a traits class, which is a model of the *ArrangementBasicTraits_2* concept. It simply uses the nested *Traits::Point_2* and *Traits::X_monotone_curve_2* to instantiate the base vertex and halfedge types, respectively. Thus, the default DCEL records store no other information, except for the topological incidence relations and the geometric data attached to vertices and edges.

```
#include <CGAL/Arr_default_dcel.h>
```

Is Model for the Concepts

ArrangementDcelWithRebind

Inherits From

```
Arr_dcel_base<Arr_vertex_base<typename Traits::Point_2>,

CGAL::Arr_face_extended_dcel<Traits,FData,V,H,F>

Definition

The *Arr_face_extended_dcel<Traits,FData,V,H,F>* class-template extends the DCEL face-records, making it possible to store extra (non-geometric) data with the arrangement faces. The class should be instantiated by an *FData* type which represents the extra data stored with each face.

Note that all types of DCEL features (namely vertex, halfedge and face) are provided as template parameters. However, by default they are defined as follows:

```
V = Arr_vertex_base<typename Traits::Point_2>
H = Arr_halfedge_base<typename Traits::X_monotone_curve_2>
F = Arr_face_base
```

```
#include <CGAL/Arr_extended_dcel.h>
```

CGAL::Arr_extended_dcel<Traits,VData,HData,FData,V,H,F>

Definition

The *Arr_extended_dcel*<Traits,VData,HData,FData,V,H,F> class-template extends the topological-features of the DCEL namely the vertex, halfedge, and face types. While it is possible to maintain extra (non-geometric) data with the curves or points of the arrangement by extending their types respectively, it is also possible to extend the vertex, halfedge, or face types of the DCEL through inheritance. As the technique to extend these types is somewhat cumbersome and difficult for inexperienced users, the *Arr_extended_dcel*<Traits,VData,HData,FData,V,H,F> class-template provides a convenient way to do that. Each one of the three features is extended with a corresponding data type provided as parameters. This class template is also parameterized with a traits class used to extract default values for the vertex, halfedge, and face base classes, which are the remaining three template parameters respectively. The default values follow:

```
V = Arr_vertex_base<typename Traits::Point_2>
H = Arr_halfedge_base<typename Traits::X_monotone_curve_2>
F = Arr_face_base
```

```
#include <CGAL/Arr_extended_dcel.h>
```

Is Model for the Concepts

ArrangementBasicTraits_2

Definition

The concept `ArrangementBasicTraits_2` defines the minimal set of geometric predicates needed for the construction and maintenance of objects of the class `Arrangement_2`, as well as performing simple queries (such as point-location queries) on such arrangements.

A model of this concept must define nested `Point_2` and `X_monotone_curve_2` types, which represent planar points and continuous x -monotone curves (a vertical segment is also considered to be *weakly* x -monotone), respectively. The x -monotone curves are assumed to be pairwise disjoint in their interiors, so they do not intersect except at their endpoints.

The x -monotone curves may be *unbounded*, namely they may have unbounded ends that lie at infinity, or *bounded*, in which case their finite endpoints are representable as `Point_2` objects. An x -monotone curve may also have one unbounded end and one finite endpoint (e.g. a ray). If unbounded curves are supported, the requirements from the traits class are extended a bit, as described below. In particular, the traits class needs to support comparisons at infinity, where we interpret comparisons at infinity as follows: Suppose we wish to compare the y -position of the hyperbolas $y_1 = \frac{1}{x}$ and $y_2 = \frac{2}{x}$ at $x = \infty$; then since there exists x_0 such that for each finite $x > x_0$ we have $y_2(x) > y_1(x)$ (in our case we can take $x_0 = 0$), we say that y_2 is *above* y_1 at infinity. Similarly, when comparing the x -positions of the vertical line $x = 0$ and the xy -minimal end of parabola $y = \frac{1}{x}$ for $x > 0$ (which has a vertical asymptote at $x = 0$), we define that the line lies to the *left* of the hyperbola. Namely, comparing curves at their unbounded ends should return the comparison result `EQUAL` only if the curves overlap.

Refines

`DefaultConstructible`, `CopyConstructible`, `Assignable`

Types

`ArrangementBasicTraits_2::Point_2` models the concept `ArrTraits::Point_2`.

`ArrangementBasicTraits_2::X_monotone_curve_2`

models the concept `ArrTraits::XMonotoneCurve_2`.

Categories

`ArrangementBasicTraits_2::Has_left_category`

indicates whether the nested functor `Compare_at_x_left_2` is provided.

`ArrangementBasicTraits_2::Arr_left_side_category`

indicates the type of the left boundary-side. Must be either `Arr_oblivious_side_tag` or `Arr_open_side_tag`.

ArrangementBasicTraits_2:: Arr_bottom_side_category

indicates the type of the bottom boundary-side. Must be either *Arr_oblivious_side_tag* or *Arr_open_side_tag*.

ArrangementBasicTraits_2:: Arr_top_side_category

indicates the type of the top boundary-side. Must be either *Arr_oblivious_side_tag* or *Arr_open_side_tag*.

ArrangementBasicTraits_2:: Arr_right_side_category

indicates the type of the right boundary-side. Must be either *Arr_oblivious_side_tag* or *Arr_open_side_tag*.

Functor Types

ArrangementBasicTraits_2:: Compare_x_2

models the concept *ArrTraits::CompareX_2*.

ArrangementBasicTraits_2:: Compare_xy_2

models the concept *ArrTraits::CompareXy_2*.

ArrangementBasicTraits_2:: Parameter_space_in_x_2

models the concept *ArrTraits::ParameterSpaceInX_2*. Required only if the traits class supports unbounded curves (the *Has_boundary_category* category is defined as *Tag_true*).

ArrangementBasicTraits_2:: Parameter_space_in_y_2

models the concept *ArrTraits::ParameterSpaceInY_2*. Required only if the traits class supports unbounded curves (the *Has_boundary_category* category is defined as *Tag_true*).

ArrangementBasicTraits_2:: Construct_min_vertex_2

models the concept *ArrTraits::ConstructMinVertex_2*.

ArrangementBasicTraits_2:: Construct_max_vertex_2

models the concept *ArrTraits::ConstructMaxVertex_2*.

ArrangementBasicTraits_2:: Is_vertical_2

models the concept *ArrTraits::IsVertical_2*.

ArrangementBasicTraits_2:: Compare_y_at_x_2

models the concept *ArrTraits::CompareYAtX_2*. If the traits class supports unbounded curves (i.e., the *Has_boundary_category* category is defined as *Tag_true*), then the type models the concept *ArrTraits::CompareYNearBoundary_2*.

ArrangementBasicTraits_2:: Compare_y_at_x_left_2

models the concept *ArrTraits::CompareYAtXLeft_2*. Required only if the *Has_left_category* category is defined as *Tag_true*.

ArrangementBasicTraits_2:: Compare_y_at_x_right_2

models the concept *ArrTraits::CompareYAtXRight_2*.

ArrangementBasicTraits_2:: Equal_2

models the concept *ArrTraits::Equal_2*.

ArrangementBasicTraits_2:: compare_x_near_boundary_2

models the concept *ArrTraits::CompareXNearBoundary_2*. Required only if the traits class supports unbounded curves (the *Has_boundary_category* category is defined as *Tag_true*).

ArrangementBasicTraits_2:: compare_y_near_boundary_2

models the concept *ArrTraits::CompareYNearBoundary_2*. Required only if the traits class supports unbounded curves (the *Has_boundary_category* category is defined as *Tag_true*).

Refines

Functor

Has Models

ArrangementBasicTraits_2::Parameter_space_in_y_2

Arr_parameter_space

fo(ArrTraits::X_monotone_curve_2 xc, Arr_curve_end ce)

determines the placement of the y-coordinate of the minimal end or maximal end of *xc* in the parameter space, that is, *ARR_BOTTOM_BOUNDARY*, *ARR_INTERIOR*, or *ARR_TOP_BOUNDARY*.

ArrTraits::CompareXNearBoundary_2

Refines

ArrTraits::CompareX_2

Has Models

ArrangementBasicTraits_2::Compare_x_near_boundary_2

Comparison_result *fo*(*ArrTraits::Point_2* *p*, *ArrTraits::X_monotone_curve_2* *xc*, *Arr_curve_end* *ce*)

returns *SMALLER*, *EQUAL*, or *LARGER* according to the *x*-ordering of a vertical line passing through the point *p* and an unbounded end of the curve *xc*. The relevant end is the minimal end, if *ce* is *MIN_END* and the maximal end if *ce* is *MAX_END*.

Precondition: the curve end has a bounded *x*-coordinate and an unbounded *y*-coordinate. Namely *xc* is vertical or has a vertical asymptote.

Comparison_result *fo.operator()*(*ArrTraits::X_monotone_curve_2* *xc1*,
 Arr_curve_end *ce1*,
 ArrTraits::X_monotone_curve_2 *xc2*,
 Arr_curve_end *ce2*)

returns *SMALLER*, *EQUAL*, or *LARGER* according to the *x*-ordering of the unbounded curve ends of *xc1* and *xc2*.

Precondition: the curve ends have a bounded *x*-coordinate and an unbounded *y*-coordinate. Namely each of *xc1* and *xc2* is vertical or has a vertical asymptote.

CompareYAtX_2

ArrangementBasicTraits_2::Compare_y_near_boundary_2

returns *SMALLER*, *EQUAL* or *LARGER* according to the y-ordering of the two curves *xc1* and *xc2* at $x = -\infty$ (if *ce* is *MIN_END*) or at $x = \infty$ (if *ce* is *MAX_END*), with the precondition that both curves have unbounded minimal (or maximal) ends that lie at $x = \pm\infty$.

ArrangementLandmarkTraits_2

Definition

The concept `ArrangementLandmarkTraits_2` refines the general traits concept by adding operations needed for the landmarks point-location strategy, namely — approximating points and connecting points with a simple x -monotone curve.

A model of this concept must define the *Approximate_number_type*, which is used to approximate the coordinates of *Point_2* instances. It is recommended to define the approximated number type as the built-in *double* type.

ArrangementXMonotoneTraits_2

Definition

The concept `ArrangementXMonotoneTraits_2` refines the basic arrangement-traits concept. A model of this concept is able to handle x -monotone curves that intersect in their interior (and points that coincide with curve interiors). This is necessary for constructing arrangements of sets of intersecting x -monotone curves.

As the resulting structure, represented by the `Arrangement_2` class, stores pairwise interior-disjoint curves, the input curves are split at the intersection points before being inserted into the arrangement. A model of this refined concept therefore needs to compute the intersections (and possibly overlaps) between two x -monotone curves and to support curve splitting.

Functor

Has Models

ArrangementXMonotoneTraits_2::Split_2

```
void          fo.split( ArrTraits::X_monotone_curve_2 xc,
                        ArrTraits::Point_2 p,
                        ArrTraits::X_monotone_curve_2& xc1,
                        ArrTraits::X_monotone_curve_2& xc2)
```

accepts an input curve *xc* and a split point *p* in its interior.
It splits *xc* at the split point into two subcurves *xc1* and *xc2*,
such that *p* is *xc1*'s *right* endpoint and *xc2*'s *left* endpoint.

ArrTraits::AreMergeable_2

Refines

Functor

Has Models

ArrangementXMonotoneTraits_2::Are_mergeable_2

```
bool fo.are_mergeable( ArrTraits::X_monotone_curve_2 xc1,
                      ArrTraits::X_monotone_curve_2 xc2)
```

accepts two x -monotone curves $xc1$ and $xc2$ that share a common endpoint, and determines whether they can be merged to form a single continuous x -monotone curve.

ArrTraits::Merge_2

Refines

Functor

Has Models

ArrangementXMonotoneTraits_2::Merge_2

```
void                fo.merge( ArrTraits::X_monotone_curve_2 xc1,  
                             ArrTraits::X_monotone_curve_2 xc2,  
                             ArrTraits::X_monotone_curve_2& xc)
```

accepts two *mergeable* *x*-monotone curves *xc1* and *xc2* (see definition above), and sets *xc* to be the merged curve.

ArrangementTraits_2

Definition

The concept `ArrangementTraits_2` allows the construction of arrangement of *general* planar curves. Models of this concept are used by the free `insert()` functions of the arrangement package and by the `Arrangement_with_history_2` class.

A model of this concept must define the nested `Curve_2` type, which represents a general planar curve that is not necessarily *x*-monotone and is not necessarily connected. Such curves are eventually subdivided into *x*-monotone subcurves and isolated points (represented by the `Point_2` and `X_monotone_curve_2` types, defined in the basic traits concept).

A model of the concept `ArrangementTraits_2` that handles arbitrary curves, which are always *x*-monotone, such as a traits class that handles linear curves may define the nested types `Curve_2` and `X_monotone_curve_2` to be of equivalent types. Moreover, defining them as of equivalent types is advantageous, as it enables a generic simple implementation of the nested Functor `Make_x_monotone_2`.

On the other hand, a model of the `ArrangementTraits_2` concept that handles arbitrary curves, which may be not *x*-monotone must define the `Curve_2` and `X_monotone_curve_2` nested types to be of different types to allow proper dispatching of the free functions that accept such curves, such as `insert()`.

ArrangementTraits_2::Make_x_monotone_2

```
template <typename OutputIterator>
OutputIterator fo( ArrTraits::Curve_2 c, OutputIterator oi)
```

subdivides the input curve *c* into *x*-monotone subcurves and isolated points, and inserts the results into a container through the given output iterator. The value type of *OutputIterator* is *CGAL::Object*, where each *Object* wraps either an *ArrTraits::X_monotone_curve_2* object or a *ArrTraits::Point_2* object. The operator returns a past-the-end iterator for the output sequence.

CGAL::Arr_segment_traits_2<Kernel>

Definition

The traits class *Arr_segment_traits_2<Kernel>* is a model of the *ArrangementTraits_2* concept that allow the construction and maintenance of arrangements of line segments. It should be parameterized with a CGAL-kernel model that is templated in turn with a number type. To avoid numerical errors and robustness problems, the number type should support exact rational arithmetic — that is, the number type should support the arithmetic operations $+$, $-$, \times and \div that should be carried out without loss of precision.

For example, instantiating the traits template with kernels such as *Cartesian<Quotient<MP_Float> >*, or *Homogeneous<Gmpz>* ensures the exact and robust operation of the application. In particular, the *Cartesian<Gmpq>* achieves the fastest running times in most cases. Using other (inexact) number types (for example, instantiating the template with *Simple_cartesian<double>*) is possible at the user's own risk: selecting an inexact number type usually leads to faster running time at the expense of possible robustness problems.

For optimal performance, we recommend instantiating the traits class with the default *Exact_predicates_exact_constructions_kernel* provided by CGAL. Using this kernel guarantees exactness and robustness, while it incurs only a minor overhead (in comparison to working with a fast, inexact number type) for most inputs.

Arr_segment_traits_2<Kernel> defines *Kernel::Point_2* as its point type. However, it does *not* define *Kernel::Segment_2* as its curve type, as one may expect. The reason is that the kernel segment is represented by its two endpoints only, while the traits class needs to store extra data with its segments, in order to efficiently operate on them. Nevertheless, the nested *X_monotone_curve_2* and *Curve_2* types (in this case both types refer to the same class, as every line segment is (weakly) *x*-monotone) are however convertible to the *Kernel::Segment_2*.

Arr_segment_traits_2<Kernel> achieves faster running times than the *Arr_non_caching_segment_traits_2<Kernel>* traits-class, when arrangements with relatively many intersection points are constructed. It also allows for working with less accurate, yet computationally efficient number types, such as *Quotient<MP_Float>*, which represents floating-point numbers with an unbounded mantissa, but with a bounded exponent. Using this traits class is therefore highly recommended for almost all applications that rely on arrangements of line segments. On the other hand, *Arr_segment_traits_2<Kernel>* uses more space and stores extra data with each segment, so constructing arrangements of huge sets of non-intersecting segments (or segments that intersect very sparsely) could be more efficient with the *Arr_non_caching_segment_traits_2* traits-class.

```
#include <CGAL/Arr_segment_traits_2.h>
```

ArrangementTraits_2

ArrangementLandmarkTraits_2

CGAL::Arr_non_caching_segment_basic_traits_2<Kernel>

Definition

The traits class *Arr_non_caching_segment_basic_traits_2<Kernel>* is a model of the *ArrangementTraits_2* concept that allow the construction and maintenance of arrangements of sets of pairwise interior-disjoint line segments. It is templated with a CGAL-*Kernel* model, and it is derived from it. This traits class is a thin layer above the parameterized kernel. It inherits the *Point_2* from the kernel and its *X_monotone_curve_2* type is defined as *Kernel::Segment_2*. Most traits-class functor are inherited from the kernel functor, and the traits class only supplies the necessary functors that are not provided by the kernel. The kernel is parameterized with a number type, which should support the arithmetic operations $+$, $-$ and \times in an exact manner in order to avoid robustness problems. Using *Cartesian<MP_Float>* or *Cartesian<Gmpz>* are possible instantiations for the kernel. Using other (inexact) number types (for example, instatiating the template with *Simple_cartesian<double>*) is also possible, at the user's own risk.

```
#include <CGAL/Arr_non_caching_segment_basic_traits_2.h>
```

Is Model for the Concepts

ArrangementLandmarkTraits_2

CGAL::Arr_non_caching_segment_traits_2<Kernel>

Definition

The traits class *Arr_non_caching_segment_traits_2<Kernel>* is a model of the *ArrangementTraits_2* concept that allows the construction and maintenance of arrangements of line segments. It is parameterized with a CGAL-*Kernel* type, and it is derived from it. This traits class is a thin layer above the parameterized kernel. It inherits the *Point_2* from the kernel and its *X_monotone_curve_2* and *Curve_2* types are both defined as *Kernel::Segment_2*. Most traits-class functor are inherited from the kernel functor, and the traits class only supplies the necessary functors that are not provided by the kernel. The kernel is parameterized with a number type, which should support exact rational arithmetic in order to avoid robustness problems, although other number types could be used at the user's own risk.

The traits-class implementation is very simple, yet may lead to a cascaded representation of intersection points with exponentially long bit-lengths, especially if the kernel is parameterized with a number type that does not perform normalization (e.g. *Quotient<MP_Float>*). The *Arr_segment_traits_2* traits class avoids this cascading problem, and should be the default choice for implementing arrangements of line segments. It is recommended to use *Arr_non_caching_segment_traits_2<Kernel>* only for very sparse arrangements of huge sets of input segments.

Arr_segment_traits_2<Kernel>

CGAL::Arr_linear_traits_2<Kernel>

Definition

The traits class *Arr_linear_traits_2<Kernel>* is a model of the *ArrangementTraits_2* concept that allows for the construction and maintenance of arrangements of linear objects which may be bounded (line segments) or unbounded (rays and lines). The traits class is parameterized with a CGAL-kernel model; see the reference page of *Arr_segment_traits_2<Kernel>* (page 2145) for further explanations and recommendations on choosing a kernel.

Arr_linear_traits_2<Kernel> defines *Kernel::Point_2* as its point type. The nested *X_monotone_curve_2* and *Curve_2* types defined by the traits class (as is the case with the various segment-traits classes, both types refer to the same class, as every linear object is (weakly) *x*-monotone), are constructible from a point, a line segment, a ray and from a line (objects of types *Kernel::Point_2*, *Kernel::Segment_2*, *Kernel::Ray_2* and *Kernel::Line_2*, respectively). On the other hand, when we are given a curve we can find out its actual type and convert it to the respective kernel object (say, to a *Kernel::Ray_2*).

```

CGAL::Arr_polyline_traits_2<SegmentTraits>

Definition

The traits class *Arr_polyline_traits_2<SegmentTraits>* is a model of the *ArrangementTraits_2* concept. It handles piecewise linear curves, commonly referred to as polylines. Each polyline is a chain of segments, where each two neighboring segments in the chain share a common endpoint. The traits class exploits the functionality of the *SegmentTraits* template-parameter to handle the segments that comprise the polyline curves.

The class instantiated for the template parameter *SegmentTraits* must be a model of the *ArrangementTraits_2* concept that handles line segments (e.g., *Arr_segment_traits_2<Kernel>* or *Arr_non_caching_segment_traits_2<Kernel>*, where the first alternative is recommended).

The number type used by the injected segment traits should support exact rational arithmetic (that is, the number type should support the arithmetic operations $+$, $-$, \times and \div that should be carried out without loss of precision), in order to avoid robustness problems, although other inexact number types could be used at the user's own risk.

```
#include <CGAL/Arr_polyline_traits_2.h>
```

Is Model for the Concepts

ArrangementTraits_2

ArrangementLandmarkTraits_2

Class Arr_polyline_traits_2<SegmentTraits>::Curve_2

The *Curve_2* class nested within the polyline traits is used to represent general continuous piecewise-linear curves (a polyline can be self-intersecting) and support their construction from any range of points.

The copy and default constructor as well as the assignment operator are provided for polyline curves. In addition, an *operator<<* for the curves is defined for standard output streams, and an *operator>>* for the curves is defined for standard input streams.

Types

Arr_polyline_traits_2<SegmentTraits>::Curve_2::const_iterator

A bidirectional iterator that allows traversing the points that comprise a polyline curve.

Arr_polyline_traits_2<SegmentTraits>::Curve_2::const_reverse_iterator

A bidirectional iterator that allows traversing the points that comprise a polyline curve.

Creation

Arr_polyline_traits_2<SegmentTraits>::Curve_2 pi;

default constructor that constructs an empty polyline.

template <class InputIterator>

Arr_polyline_traits_2<SegmentTraits>::Curve_2 pi(Iterator first, Iterator last);

constructs a polyline defined by the given range of points *[first, last)* (the value-type of *InputIterator* must be *SegmentTraits::Point_2*. If the range contains $(n + 1)$ points labeled (p_0, p_1, \dots, p_n) , the generated polyline consists of n segments, where the k th segment is defined by the endpoints $[p_{k-1}, p_k]$. The first point in the range is considered as the source point of the polyline while the last point is considered as its target.

Precondition: There are at least two points in the range.

Access Functions

<i>size_t</i>	<i>pi.points()</i>	returns the number of points that comprise the polyline. Note that if there are n points in the polyline, it is comprised of $(n - 1)$ segments.
---------------	--------------------	--

<i>const_iterator</i>	<i>pi.begin()</i>	returns an iterator pointing at the source point of the polyline.
-----------------------	-------------------	---

<i>const_iterator</i>	<i>pi.end()</i>	returns an iterator pointing after the end of the polyline.
-----------------------	-----------------	---

<i>const_iterator</i>	<i>pi.rbegin()</i>	returns an iterator pointing at the target point of the polyline.
-----------------------	--------------------	---

<i>const_iterator</i>	<i>pi.rend()</i>	returns an iterator pointing before the beginning of the polyline.
-----------------------	------------------	--

<i>size_t</i>	<i>pi.size()</i>	returns the number of line segments comprising the polyline (equivalent to <i>pi.points() - 1</i>).
---------------	------------------	--

typename SegmentTraits::X_monotone_curve_2

<i>pi[size_t k]</i>	returns the k th segment of the polyline. <i>Precondition:</i> k is not greater or equal to <i>pi.size() - 1</i> .
----------------------	---

<i>Bbox_2</i>	<i>pi.bbox()</i>	return a bounding box of the polyline <i>pi</i> .
---------------	------------------	---

Operations

<i>void</i>	<i>pi.push_back(Point_2 p)</i>	adds a new point to the polyline, which becomes the new target point of <i>pi</i> .
-------------	---------------------------------	---

void *pi.clear()* resets the polyline.

Class `Arr_polyline_traits_2<SegmentTraits>::X_monotone_curve_2`

The *X_monotone_curve_2* class nested within the polyline traits is used to represent *x*-monotone piecewise linear curves. It inherits from the *Curve_2* type. It has a default constructor and a constructor from a range of points, just like the *Curve_2* class. However, there is precondition that the point range define an *x*-monotone polyline.

The points that define the *x*-monotone polyline are always stored in an ascending lexicographical *xy*-order, so their order may be reversed with respect to the input sequence. Also note that the *x*-monotonicity ensures that an *x*-monotone polyline is never self-intersecting (thus, a self-intersecting polyline will be subdivided to several interior-disjoint *x*-monotone subcurves).

Arr_segment_traits_2<Kernel>

Arr_non_caching_segment_traits_2<Kernel>

CGAL::Arr_circle_segment_traits_2<Kernel>

Definition

The class *Arr_circle_segment_traits_2<Kernel>* is a model of the *ArrangementTraits_2* concept and can be used to construct and maintain arrangements of circular arcs and line segments.

The traits class must be instantiated with a geometric kernel, such that the supporting circles of the circular arcs are of type *Kernel::Circle_2* and the supporting lines of the line segments are of type *Kernel::Line_2*. Thus, the coordinates of the center of supporting circles, and its squared radius are of type *Kernel::FT*, which should be an exact rational number-type; similarly, the coefficients of each supporting line $ax + by + c = 0$ are also of type *Kernel::FT*. Note however that the intersection point between two such arcs do not have rational coordinates in general. For this reason, we do not require the endpoints of the input arcs and segments to have rational coordinates.

The nested *Point_2* type defined by the traits class is therefore *different* than the *Kernel::Point_2* type. Its coordinates are of type *CoordNT*, and represent real numbers obtained from solving quadratic equations with rational coordinates. A number of type *CoordNT* can therefore be expressed as $\alpha + \beta\sqrt{\gamma}$, where α , β and γ are all rational numbers. The definition of the curve and *x*-monotone curve types nested in the traits class are detailed below.

```
#include <CGAL/Arr_circle_segment_traits_2.h>
```

Is Model for the Concepts

ArrangementTraits_2

Class Arr_circle_segment_traits_2<Kernel>::CoordNT

The *CoordNT* number-type nested within the traits class represents an algebraic number of degree 2; it can be represented as $\alpha + \beta\sqrt{\gamma}$, where α , β and γ are all rational numbers of type *Kernel::FT*.

Types

Arr_circle_segment_traits_2<Kernel>::CoordNT::Rational
the *Kernel::FT* type.

Creation

```
Arr_circle_segment_traits_2<Kernel>::CoordNT x;  
creates a variable whose value is 0.
```

```
Arr_circle_segment_traits_2<Kernel>::CoordNT x(Rational alpha);  
creates a variable whose value is the rational number  $\alpha$ .
```

Arr_circle_segment_traits_2<Kernel>::CoordNT *x*(*Rational* *alpha*, *Rational* *beta*, *Rational* *gamma*);

creates a variable whose value is the algebraic number $\alpha + \beta\sqrt{\gamma}$.

Access Functions

bool *x.is_rational()* determines whether *x* is rational.

Rational *x.alpha()* returns α .

Rational *x.beta()* returns β (0 if *x* is rational).

Rational *x.gamma()* returns γ (0 if *x* is rational).

Operators

The *CoordNT* number-type supports all arithmetic operations with rational numbers of type *Kernel::FT*. For example, it is possible to compute $x + q$, $q - x$, $x += q$, etc. where *q* is rational.

The global functions *CGAL::sign(x)*, *CGAL::square(x)*, *CGAL::to_double(x)* and *CGAL::compare(x,y)*, where *x* and *y* are of type *CoordNT*, are also supported.

It is also possible to call *CGAL::to_double(x)* to convert *x* to a rational number, with the precondition that it is indeed rational.

Class *Arr_circle_segment_traits_2<Kernel>::Point_2*

The *Point_2* number-type nested within the traits class represents a Cartesian point whose coordinates are algebraic numbers of type *CoordNT*.

Types

Arr_circle_segment_traits_2<Kernel>::Point_2:: Rational
the *Kernel::FT* type.

Arr_circle_segment_traits_2<Kernel>::Point_2:: CoordNT
the algebraic number-type.

Creation

Arr_circle_segment_traits_2<Kernel>::Point_2 *p*;
default constructor.

Arr_circle_segment_traits_2<Kernel>::Point_2 p(Rational x, Rational y);

creates the point (x,y).

Arr_circle_segment_traits_2<Kernel>::Point_2 p(CoordNT x, CoordNT y);

creates the point (x,y).

Access Functions

CoordNT p.x() returns the *x*-coordinate.

CoordNT p.y() returns the *y*-coordinate.

Class *Arr_circle_segment_traits_2<Kernel>::Curve_2*

The *Curve_2* class nested within the traits class can represent arbitrary circular arcs, full circles and line segments and support their construction in various ways. The copy and default constructor as well as the assignment operator are provided. In addition, an *operator<<* for the curves is defined for standard output streams.

Creation

Arr_circle_segment_traits_2<Kernel>::Curve_2 cv(typename Kernel::Segment_2 seg);

constructs an curve corresponding to the line segment *seg*.

*Arr_circle_segment_traits_2<Kernel>::Curve_2 cv(typename Kernel::Point_2 source,
typename Kernel::Point_2 target)*

constructs an curve corresponding to the line segment directed from *source* to *target*, both having rational coordinates.

*Arr_circle_segment_traits_2<Kernel>::Curve_2 cv(typename Kernel::Line_2 line,
Point_2 source,
Point_2 target)*

constructs an curve corresponding to the line segment supported by the given line, directed from *source* to *target*. Note that the two endpoints may have one-root coordinates.

Precondition: Both endpoints must lie on the given supporting line.

Arr_circle_segment_traits_2<Kernel>::Curve_2 cv(typename Kernel::Circle_2 circ);

constructs an curve corresponding to the given circle. *circ* has a center point with rational coordinates and its *squared* radius is rational.

Arr_circle_segment_traits_2<Kernel>::Curve_2 *cv*(*typename Kernel::Point_2* *c*,
typename Kernel::FT *r*,
Orientation orient = COUNTERCLOCKWISE)

constructs an curve corresponding to a circle centered at the rational point *c* whose radius *r* is rational.

Arr_circle_segment_traits_2<Kernel>::Curve_2 *cv*(*typename Kernel::Circle_2* *circ*,
Point_2 source,
Point_2 target)

constructs a circular arc supported by *circ*, which has a center point with rational coordinates and whose *squared* radius is rational, with the given endpoints. The orientation of the arc is the same as the orientation of *circ*.

Precondition: Both endpoints must lie on the given supporting circle.

Arr_circle_segment_traits_2<Kernel>::Curve_2 *cv*(*typename Kernel::Point_2* *c*,
typename Kernel::FT *r*,
Orientation orient,
Point_2 source,
Point_2 target)

constructs a circular arc supported by a circle centered at the rational point *c* whose radius *r* is rational, directed from *source* to *target* with the given orientation.

Precondition: Both endpoints must lie on the supporting circle.

Arr_circle_segment_traits_2<Kernel>::Curve_2 *cv*(*typename Kernel::Point_2* *source*,
typename Kernel::Point_2 *mid*,
typename Kernel::Point_2 *target*)

constructs an circular arc whose endpoints are *source* and *target* that passes through *mid*. All three points have rational coordinates.

Precondition: The three points must not be collinear.

ArrangementTraits_2

CGAL::Arr_circular_line_arc_traits_2<CircularKernel>

#include <CGAL/Arr_circular_line_arc_traits_2.h>

Definition

This class is a traits class for CGAL arrangements, built on top of a model of concept *CircularKernel*. It provides curves that can be of both types *CGAL::Line_arc_2<CircularKernel>* or *CGAL::Circular_arc_2<CircularKernel>*.

It uses the **boost::variant**.

Is Model for the Concepts

ArrangementTraits_2

CGAL::Arr_conic_traits_2<RatKernel,AlgKernel,NtTraits>

Definition

The class `Arr_conic_traits_2<RatKernel,AlgKernel,NtTraits>` is a model of the *ArrangementTraits_2* concept and can be used to construct and maintain arrangements of bounded segments of algebraic curves of degree 2 at most, also known as *conic curves*.

A general conic curve C is the locus of all points (x,y) satisfying the equation: $rx^2 + sy^2 + txy + ux + vy + w = 0$, where:

- If $4rs - t^2 > 0$, C is an ellipse. A special case occurs when $r = s$ and $t = 0$, when C becomes a circle.
- If $4rs - t^2 < 0$, C is a hyperbola.
- If $4rs - t^2 = 0$, C is a parabola. A degenerate case occurs when $r = s = t = 0$, when C is a line.

A *bounded conic arc* is defined as either of the following:

- A full ellipse (or a circle) C .
- The tuple $\langle C, p_s, p_t, o \rangle$, where C is the supporting conic curve, with the arc endpoints being p_s and p_t (the source and target points, respectively). The orientation o indicates whether we proceed from p_s to p_t in a clockwise or in a counterclockwise direction. Note that C may also correspond to a line or to pair of lines — in this case o may specify a *COLLINEAR* orientation.

A very useful subset of the set of conic arcs are line segments and circular arcs, as arrangements of circular arcs and line segments have some interesting applications (e.g. offsetting polygons, motion planning for a disc robot, etc.). Circular arcs and line segment are simpler objects and can be dealt with more efficiently than arbitrary arcs. For these reasons, it is possible to construct conic arcs from segments and from circles. Using these constructors is highly recommended: It is more straightforward and also speeds up the arrangement construction. However, in case the set of input curves contain only circular arcs and line segments, it is recommended to use the `Arr_circle_segment_2` class to achieve faster running times.

In our representation, all conic coefficients (namely r, s, t, u, v, w) must be rational numbers. This guarantees that the coordinates of all arrangement vertices (in particular, those representing intersection points) are algebraic numbers of degree 4 (a real number α is an algebraic number of degree d if there exist a polynomial p with integer coefficient of degree d such that $p(\alpha) = 0$). We therefore require separate representations of the curve coefficients and the point coordinates. The *NtTraits* should be instantiated with a class that defines nested *Integer*, *Rational* and *Algebraic* number types and supports various operations on them, yielding certified computation results (for example, it can convert rational numbers to algebraic numbers and can compute roots of polynomials with integer coefficients). The other template parameters, *RatKernel* and *AlgKernel* should be geometric kernels templated with the *NtTraits::Rational* and *NtTraits::Algebraic* number types, respectively. It is recommended to instantiate the *CORE_algebraic_number_traits* class as the *NtTraits* parameter, with *Cartesian<NtTraits::Rational>* and *Cartesian<NtTraits::Algebraic>* instantiating the two kernel types, respectively. The number types in this case are provided by the CORE library, with its ability to exactly represent simple algebraic numbers.

The traits class inherits its point type from *AlgKernel::Point_2*, and defines a curve and x -monotone curve types, as detailed below.

```
#include <CGAL/Arr_conic_traits_2.h>
```

Is Model for the Concepts

ArrangementTraits_2

ArrangementLandmarkTraits_2

Types

Arr_conic_traits_2<RatKernel,AlgKernel,NtTraits>:: Rational

the *NtTraits::Rational* type (and also the *RatKernel::FT* type).

Arr_conic_traits_2<RatKernel,AlgKernel,NtTraits>:: Algebraic

the *NtTraits::Algebraic* type (and also the *AlgKernel::FT* type).

Class *Arr_conic_traits_2<RatKernel,AlgKernel,NtTraits>::Curve_2*

The *Curve_2* class nested within the conic-arc traits can represent arbitrary conic arcs and support their construction in various ways. The copy and default constructor as well as the assignment operator are provided for conic arcs. In addition, an *operator<<* for the curves is defined for standard output streams.

Creation

Arr_conic_traits_2<RatKernel,AlgKernel,NtTraits>::Curve_2 a(typename RatKernel::Segment_2 seg);

constructs an arc corresponding to the line segment *seg*.

Arr_conic_traits_2<RatKernel,AlgKernel,NtTraits>::Curve_2 a(typename RatKernel::Circle_2 circ);

constructs an arc corresponding to the full circle *circ* (note that this circle has a center point with rational coordinates and rational squared radius).

*Arr_conic_traits_2<RatKernel,AlgKernel,NtTraits>::Curve_2 a(typename RatKernel::Circle_2 circ,
Orientation o,
Point_2 ps,
Point_2 pt)*

constructs a circular arc supported by the circle *circ*, going in the given orientation *o* from the source point *ps* to its target point *pt*.

Precondition: *ps* and *pt* both lie on the circle *circ*.

Precondition: *o* is not *COLLINEAR*.

Arr_conic_traits_2<RatKernel,AlgKernel,NtTraits>::Curve_2 *a*(*typename RatKernel::Point_2* *p1*,
typename RatKernel::Point_2 *p2*,
typename RatKernel::Point_2 *p3*)

constructs a circular arc going from *p1* (its source point) through *p2* to *p3* (its target point). Note that all three points have rational coordinates. The orientation of the arc is determined automatically.

Precondition: The three points are not collinear.

Arr_conic_traits_2<RatKernel,AlgKernel,NtTraits>::Curve_2 *a*(*Rational* *r*,
Rational *s*,
Rational *t*,
Rational *u*,
Rational *v*,
Rational *w*)

constructs a conic arc that corresponds to the full conic curve $rx^2 + sy^2 + txy + ux + vy + w = 0$.

Precondition: As a conic arc must be bounded, the given curve must be an ellipse, that is $4rs - t^2 > 0$.

Arr_conic_traits_2<RatKernel,AlgKernel,NtTraits>::Curve_2 *a*(*Rational* *r*,
Rational *s*,
Rational *t*,
Rational *u*,
Rational *v*,
Rational *w*,
Orientation *o*,
Point_2 *ps*,
Point_2 *pt*)

constructs a conic arc supported by the conic curve $rx^2 + sy^2 + txy + ux + vy + w = 0$, going in the given orientation *o* from the source point *ps* to its target point *pt*.

Precondition: *ps* and *pt* both satisfy the equation of the supporting conic curve and define a bounded segment of this curve (e.g. in case of a hyperbolic arc, both point should be located on the same branch of the hyperbola).

Precondition: *o* is not *COLLINEAR* if the supporting conic is curves, and must be *COLLINEAR* if it is not curved (a line or a line-pair).

Arr_conic_traits_2<RatKernel,AlgKernel,NtTraits>::Curve_2 *a*(*typename RatKernel::Point_2* *p1*,
typename RatKernel::Point_2 *p2*,
typename RatKernel::Point_2 *p3*,
typename RatKernel::Point_2 *p4*,

typename RatKernel::Point_2 p5)

constructs a conic arc going from $p1$ (its source point) through $p2$, $p3$ and $p4$ (in this order) to $p5$ (its target point). Note that all five points have rational coordinates. The orientation of the arc is determined automatically.

Precondition: No three points of the five are not collinear.

Precondition: The five points define a valid arc, in their given order.

Arr_conic_traits_2<RatKernel,AlgKernel,NtTraits>::Curve_2 a(Rational r,
Rational s,
Rational t,
Rational u,
Rational v,
Rational w,
Orientation o,
Point_2 app_ps,
Rational r1,
Rational s1,
Rational t1,
Rational u1,
Rational v1,
Rational w1,
Point_2 app_pt,
Rational r2,
Rational s2,
Rational t2,
Rational u2,
Rational v2,
Rational w2)

constructs a conic arc supported by the conic curve $rx^2 + sy^2 + txy + ux + vy + w = 0$, going in the given orientation o from its source point to its target point. In this case only some approximations of the endpoints (app_ps and app_pt , respectively) is available, and their exact locations are given implicitly, specified by the intersections of the supporting conic curve with $r_1x^2 + s_1y^2 + t_1xy + u_1x + v_1y + w_1 = 0$ and $r_2x^2 + s_2y^2 + t_2xy + u_2x + v_2y + w_2 = 0$, respectively.

Precondition: The two auxiliary curves specifying the endpoints really intersect with the supporting conic curve, such that the arc endpoints define a bounded segment of the supporting curve (e.g. in case of a hyperbolic arc, both point should be located on the same branch of the hyperbola).

Precondition: o is not *COLLINEAR* if the supporting conic is curves, and must be *COLLINEAR* if it is not curved (a line or a line-pair).

Access Functions

<i>bool</i>	<i>a.is_valid()</i>	indicates whether <i>a</i> is a valid conic arc. As the precondition to some of the constructor listed above are quite complicated, their violation does not cause the program to abort. Instead, the constructed arc is invalid (a defaultly constructed arc is also invalid). It is however recommended to check that a constructed arc is valid before inserting it to an arrangement, as this operation <i>will</i> cause the program to abort.
<i>bool</i>	<i>a.is_x_monotone()</i>	determines whether the arc is <i>x</i> -monotone, namely each vertical line intersects it at most once. A vertical line segment is also considered (weakly) <i>x</i> -monotone.
<i>bool</i>	<i>a.is_y_monotone()</i>	determines whether the arc is <i>y</i> -monotone, namely each horizontal line intersects it at most once. A horizontal line segment is also considered (weakly) <i>x</i> -monotone.
<i>bool</i>	<i>a.is_full_conic()</i>	indicates whether the arc represents a full conic curve (en ellipse or a circle).

The six following methods return the coefficients of the supported conic, after their conversion to integer number (represented by the *Integer* type of the *NtTraits* class):

<i>typename NtTraits::Integer</i>	<i>a.r()</i>	returns the coefficient of x^2 .
<i>typename NtTraits::Integer</i>	<i>a.s()</i>	returns the coefficient of t^2 .
<i>typename NtTraits::Integer</i>	<i>a.t()</i>	returns the coefficient of xy .
<i>typename NtTraits::Integer</i>	<i>a.u()</i>	returns the coefficient of x .
<i>typename NtTraits::Integer</i>	<i>a.v()</i>	returns the coefficient of y .
<i>typename NtTraits::Integer</i>	<i>a.w()</i>	returns the free coefficient.
<i>Point_2</i>	<i>a.source()</i>	returns the source point of the arc. <i>Precondition:</i> <i>a</i> is not a full conic curve.
<i>Point_2</i>	<i>a.target()</i>	returns the target point of the arc. <i>Precondition:</i> <i>a</i> is not a full conic curve.
<i>Orientation</i>	<i>a.orientation()</i>	returns the orientation of the arc.
<i>Bbox_2</i>	<i>a.bbox()</i>	return a bounding box of the arc <i>a</i> .

Operations

<i>void</i>	<i>a.set_source(Point_2 ps)</i>	sets a new source point for the conic arc. <i>Precondition:</i> <i>ps</i> lies on the supporting conic of <i>a</i> .
<i>void</i>	<i>a.set_target(Point_2 pt)</i>	sets a new target point for the conic arc. <i>Precondition:</i> <i>pt</i> lies on the supporting conic of <i>a</i> .

Class **Arr_conic_traits_2<RatKernel,AlgKernel,NtTraits>::X_monotone_curve_2**

The *X_monotone_curve_2* class nested within the conic-arc traits is used to represent *x*-monotone conic arcs. It inherits from the *Curve_2* type, therefore supports the access methods and the operations listed above.

For efficiency reasons, we recommend users not to construct x -monotone conic arc directly, but rather use the *Make_x_monotone_2* functor supplied by the conic-arc traits class to convert conic curves to x -monotone curves.

Creation

Arr_conic_traits_2<*RatKernel*,*AlgKernel*,*NtTraits*>::*X_monotone_curve_2* *xa*(*Curve_2* *arc*);

converts the given arc to an x -monotone arc.

Precondition: *arc* is x -monotone.

Access Functions

<i>Point_2</i>	<i>xa.left()</i>	returns the left (lexicographically smaller) endpoint of <i>xa</i> .
<i>Point_2</i>	<i>xa.right()</i>	returns the right (lexicographically larger) endpoint of <i>xa</i> .

CGAL::Arr_rational_arc_traits_2<AlgKernel,NtTraits>

Definition

The traits class *Arr_rational_arc_traits_2<AlgKernel,NtTraits>* is a model of the *ArrangementTraits_2* concept. It handles bounded or unbounded segments of rational functions, referred to as *rational arcs* (in particular, a rational arc may correspond to the entire graph of a rational function), and enables the construction and maintenance of arrangements of such arcs. Rational functions, and polynomial functions in particular, are not only interesting in their own right, they are also very useful for approximating or interpolating more complicated curves.

A rational function $y = \frac{P(x)}{Q(x)}$ is defined by two polynomials P and Q of arbitrary degrees. In particular, if $Q(x) = 1$ then the function is a simple polynomial function. A bounded rational arc is defined by the graph of a rational function over some interval $[x_{\min}, x_{\max}]$, where Q does not have any real roots in this interval (thus the arc does not contain any poles). However, our traits class is also capable of representing functions defined over an unbounded x -range, namely a “ray” defined on $(-\infty, x_{\max}]$ or on $[x_{\min}, \infty)$, or an entire function defined for all real x values. Note that a rational arc is unbounded even if it is defined over some bounded interval, yet Q has zeros in this interval.

In our representation, all polynomial coefficients (the coefficients of P and Q) must be rational numbers. This guarantees that the x -coordinates of all arrangement vertices (in particular, those representing intersection points) can be represented as roots of polynomials with integer coefficients — namely, algebraic numbers. The y -coordinates can be obtained by simple arithmetic operations on the x -coordinates, hence they are also algebraic numbers.

We therefore require separate representations of the curve coefficients and the point coordinates. The *NtTraits* should be instantiated with a class that defines nested *Integer*, *Rational* and *Algebraic* number types and supports various operations on them, yielding certified computation results (for example, it can convert rational numbers to algebraic numbers and can compute roots of polynomials with integer coefficients). The *AlgKernel* template-parameter should be a geometric kernel templated with the *NtTraits::Algebraic* number-type. It is recommended to instantiate the *CORE_algebraic_number_traits* class as the *NtTraits* parameter, with *Cartesian<NtTraits::Algebraic>* instantiating the kernel. The number types in this case are provided by the *CORE* library, with its ability to exactly represent simple algebraic numbers.

The traits class defined its point type to be *AlgKernel::Point_2*, and defines a curve type (and an identical x -monotone curve type, as a rational arc is always x -monotone by definition) as detailed below.

```
#include <CGAL/Arr_rational_arc_traits_2.h>
```

Is Model for the Concepts

ArrangementTraits_2

Class Arr_rational_arc_traits_2<AlgKernel,NtTraits>::Curve_2

The *Curve_2* class nested within the rational-arc traits is used to represent rational arcs and support their construction from a single polynomial and an x -definition range or from a pair of polynomials and an x -definition range. The copy and default constructor as well as the assignment operator are provided for rational arcs. In addition, an *operator<<* for the arcs is defined for standard output streams.

Types

Arr_rational_arc_traits_2<AlgKernel,NtTraits>::Curve_2::Rat_vector

A vector of rational numbers (equivalent to *std::vector<typename NtTraits::Rational>*).

Arr_rational_arc_traits_2<AlgKernel,NtTraits>::Curve_2::Polynomial

the *NtTraits::Polynomial* type (a polynomial with integer coefficients).

Creation

Arr_rational_arc_traits_2<AlgKernel,NtTraits>::Curve_2 a;

default constructor.

Arr_rational_arc_traits_2<AlgKernel,NtTraits>::Curve_2 a(Rat_vector p_coeffs);

constructs an arc that corresponds to the polynomial $y = P(x)$, defined for every real x . The vector *p_coeffs* specifies the coefficients of $P(x)$, where the polynomial degree is *p_coeffs.size() - 1* and $p[k]$ is the coefficient of x^k in P .

*Arr_rational_arc_traits_2<AlgKernel,NtTraits>::Curve_2 a(Rat_vector p_coeffs,
typename NtTraits::Algebraic s_x,
bool dir_right)*

constructs an arc supported by the polynomial $y = P(x)$. If *dir_right* is *true*, the arc is defined over the interval $[s_x, \infty)$, otherwise it is defined over $(-\infty, s_x]$. The vector *p_coeffs* specifies the coefficients of $P(x)$ as above.

Precondition: $s_x \neq t_x$.

*Arr_rational_arc_traits_2<AlgKernel,NtTraits>::Curve_2 a(Rat_vector p_coeffs,
typename NtTraits::Algebraic s_x,
typename NtTraits::Algebraic t_x)*

constructs an arc supported by the polynomial $y = P(x)$, defined over the interval $[s_x, t_x]$, given by the x -coordinates of the arc's source and target. The vector *p_coeffs* specifies the coefficients of $P(x)$ as above.

Precondition: $s_x \neq t_x$.

Arr_rational_arc_traits_2<AlgKernel,NtTraits>::Curve_2 a(Rat_vector p_coeffs, Rat_vector q_coeffs);

constructs an arc supported by the rational function $y = \frac{P(x)}{Q(x)}$, defined for every real x . The vectors *p_coeffs* and *q_coeffs* specify the coefficients of $P(x)$ and $Q(x)$, respectively (see above).

Arr_rational_arc_traits_2<*AlgKernel*,*NtTraits*>::*Curve_2* *a*(*Rat_vector* *p_coeffs*,
Rat_vector *q_coeffs*,
typename NtTraits::Algebraic *s_x*,
bool *dir_right*)

constructs an arc supported by the rational function $y = \frac{P(x)}{Q(x)}$.
If *dir_right* is *true*, the arc is defined over the interval $[s_x, \infty)$,
otherwise it is defined over $(-\infty, s_x]$. The vectors *p_coeffs*
and *q_coeffs* specify the coefficients of $P(x)$ and $Q(x)$, re-
spectively (see above).

Arr_rational_arc_traits_2<*AlgKernel*,*NtTraits*>::*Curve_2* *a*(*Rat_vector* *p_coeffs*,
Rat_vector *q_coeffs*,
typename NtTraits::Algebraic *s_x*,
typename NtTraits::Algebraic *t_x*)

constructs an arc supported by the rational function $y = \frac{P(x)}{Q(x)}$,
defined over the interval $[s_x, t_x]$, given by the x -coordinates of
the arc's source and target. The vectors *p_coeffs* and *q_coeffs*
specify the coefficients of $P(x)$ and $Q(x)$, respectively (see
above).
Precondition: $s_x \neq t_x$.

Access Functions

bool *a.is_continuous()* returns whether *a* is continuous, namely whether it does not
contains any poles in its interior. x -monotone curves are
always continuous.

Polynomial *a.numerator()* returns a polynomial with integer coefficients equivalent to
 $P(x)$.

Polynomial *a.denominator()* returns a polynomial with integer coefficients equivalent to
 $Q(x)$.

Arr_parameter_space

a.source_boundary_in_x()

returns whether the x -coordinate of the source is finite or
whether it is $\pm\infty$.

Arr_parameter_space

a.source_boundary_in_y()

returns whether the y -coordinate of the source is finite or
whether it is $\pm\infty$.

Point_2

a.source()

returns the source point of the arc.
Precondition: The source is finite in both x and y .

typename NtTraits::Algebraic

a.source_x() Get the x -coordinate of the source point.
Precondition: The source point is finite in x .

typename NtTraits::Algebraic

a.source_y() Get the y -coordinate of the source point.
Precondition: The source point is finite in y .

Arr_parameter_space

a.target_boundary_in_x()

returns whether the x -coordinate of the target is finite or whether it is $\pm\infty$.

Arr_parameter_space

a.target_boundary_in_y()

returns whether the y -coordinate of the target is finite or whether it is $\pm\infty$.

Point_2 *a.target()* returns the target point of the arc.
Precondition: The target is finite in both x and y .

typename NtTraits::Algebraic

a.target_x() Get the x -coordinate of the target point.
Precondition: The target point is finite in x .

typename NtTraits::Algebraic

a.target_y() Get the y -coordinate of the target point.
Precondition: The target point is finite in y .

Arr_parameter_space

a.left_boundary_in_x()

returns whether the x -coordinate of a 's left end is finite or whether it is $\pm\infty$.

Arr_parameter_space

a.left_boundary_in_y()

returns whether the y -coordinate of a 's left end is finite or whether it is $\pm\infty$.

Point_2 *a.left()* returns the left (lexicographically smaller) endpoint of a .
Precondition: The left end is finite in both x and y .

Arr_parameter_space

a.right_boundary_in_x()

returns whether the x -coordinate of a 's right end is finite or whether it is $\pm\infty$.

Arr_parameter_space

a.right_boundary_in_y()

returns whether the y -coordinate of a 's right end is finite or whether it is $\pm\infty$.

Point_2

a.right()

returns the right (lexicographically larger) endpoint of a .
Precondition: The right end is finite in both x and y .

CGAL::Arr_Bezier_curve_traits_2<RatKernel,AlgKernel,NtTraits>

Definition

The traits class *Arr_Bezier_curve_traits_2<RatKernel,AlgKernel,NtTraits>* is a model of the *ArrangementTraits_2* concept that handles planar Bézier curves. A planar Bézier curve *B* is a parametric curve defined by a sequence of *control points* p_0, \dots, p_n as follows:

$$B(t) = (X(t), Y(t)) = \sum_{k=0}^n p_k \cdot \frac{n!}{k!(n-k)!} \cdot t^k (1-t)^{n-k}.$$

where $t \in [0, 1]$. The degree of the curve is therefore n — namely, $X(t)$ and $Y(t)$ are polynomials of degree n . Bézier curves have numerous applications in computer graphics and solid modelling. They are used, for example, in free-form sketches and for defining the true-type fonts.

In our representation, we assume that the coordinates of all control points are rational numbers (namely they are given as objects of the *RatKernel::Point_2* type), so both $X(t)$ and $Y(t)$ are polynomials with rational coefficients. The intersection points between curves are however algebraic numbers, and their exact computation is time-consuming. The traits class therefore contains a layer of geometric filtering that performs all computation in an approximate manner whenever possible, and it resorts to exact computations only when the approximate computation fails to produce an unambiguous result.

We therefore require separate representations of the control points and the intersection points. The *NtTraits* should be instantiated with a class that defines nested *Integer*, *Rational* and *Algebraic* number types and supports various operations on them, yielding certified computation results (for example, it can convert rational numbers to algebraic numbers and can compute roots of polynomials with integer coefficients). The other template parameters, *RatKernel* and *AlgKernel* should be geometric kernels templated with the *NtTraits::Rational* and *NtTraits::Algebraic* number types, respectively. It is recommended to instantiate the *CORE_algebraic_number_traits* class as the *NtTraits* parameter, with *Cartesian<NtTraits::Rational>* and *Cartesian<NtTraits::Algebraic>* instantiating the two kernel types, respectively. The number types in this case are provided by the CORE library, with its ability to exactly represent simple algebraic numbers.

```
#include <CGAL/Arr_Bezier_curve_traits_2.h>
```

Is Model for the Concepts

ArrangementTraits_2

Types

Arr_Bezier_curve_traits_2<RatKernel,AlgKernel,NtTraits>:: Rational

the *NtTraits::Rational* type (and also the *RatKernel::FT* type).

Arr_Bezier_curve_traits_2<RatKernel,AlgKernel,NtTraits>:: Algebraic

the *NtTraits::Algebraic* type (and also the *AlgKernel::FT* type).

Class `Arr_Bezier_curve_traits_2<RatKernel,AlgKernel,NtTraits>::Curve_2`

The *Curve_2* class nested within the Bézier traits class is used to represent a Bézier curve of arbitrary degree, which is defined by a sequence of rational control points. In addition to the methods listed below, the I/O operators *operator<<* and *operator>>* for standard output-streams are also supported. The copy constructor and assignment operator are supported as well.

Creation

`Arr_Bezier_curve_traits_2<AlgKernel,NtTraits>::Curve_2 B;`

default constructor.

`template <class InputIterator>`

`Arr_Bezier_curve_traits_2<AlgKernel,NtTraits>::Curve_2 B(InputIterator pts_begin, InputIterator pts_end);`

constructs a Bézier curve as defined by the given range of control points. The value-type of *InputIterator* is *RatKernel::Point_2*.

Precondition: The input range must contain at least two control points.

Access Functions

`size_t B.number_of_control_point()`

returns the number of control points that define *B*.

`typename RatKernel::Point_2`

`B.control_point(size_t k)`

returns the *k*th control point. Note that the first control point equals the curve source, while the last control point equals its target. The rest of the control points do not lie on the curve.

Precondition: *k* is smaller than the number of control points.

`typename RatKernel::Point_2`

`B(Rational t)`

returns the point *B(t)* on the curve that corresponds to the given rational parameter value.

`typename AlgKernel::Point_2`

`B(Algebraic t)`

returns the point *B(t)* on the curve that corresponds to the given algebraic parameter value.

Class `Arr_Bezier_curve_traits_2<RatKernel,AlgKernel,NtTraits>::Point_2`

The *Point_2* class nested within the B zier traits class is used to represent: (i) an endpoint of a B zier curve, (ii) a vertical tangency point of a curve, used to subdivide it into x -monotone subcurve, and (iii) an intersection point between two curves. While, points of type (i) have rational coordinates and are given as part of the input, points of the two latter types have algebraic coordinates. However, to speed up the arrangement construction, such point are not computed in an exact manner, and instead are given in an approximate representation. Note that the exact coordinates of a point may only be accessed if it is exactly computed.

In addition to the methods listed below, the copy constructor and assignment operator for *Point_2* objects are also supported.

Creation

`Arr_Bezier_curve_traits_2<AlgKernel,NtTraits>::Point_2 p;`

default constructor.

`Arr_Bezier_curve_traits_2<AlgKernel,NtTraits>::Point_2 p(Curve_2 B, Algebraic t_0);`

constructs the point $B(t_0)$ on the given curve. As t_0 is an algebraic number, the point has algebraic coordinates.

`Arr_Bezier_curve_traits_2<AlgKernel,NtTraits>::Point_2 p(Curve_2 B, Rational t_0);`

constructs the point $B(t_0)$ on the given curve. As t_0 is a rational number, the point has rational coordinates.

Access Functions

`std::pair<double, double>`

`p.approximate()` returns the approximated coordinates of p .

`bool`

`p.is_exact()` returns whether the coordinates of p are computed in an exact manner.

`Algebraic`

`p.x()` returns the x -coordinate of p .
Precondition: p is exactly computed.

`Algebraic`

`p.y()` returns the y -coordinate of p .
Precondition: p is exactly computed.

`bool`

`p.is_rational()` returns whether the coordinates of p are rational numbers.

`typename RatKernel::Point_2`

`typename RatKernel::Point_2 (p)`

casts p to a point with rational coordinates.
Precondition: p has rational coordinates.

Class Arr_Bezier_curve_traits_2<RatKernel,AlgKernel,NtTraits>::X_monotone_curve_2

The *X_monotone_curve_2* class nested within the Bézier traits is used to represent *x*-monotone subcurves of Bézier curves. The subcurve is defined by a supporting Bézier curve $B(t)$ and a range of definition in the parameter space $[t_1, t_2] \subseteq [0, 1]$, where $B(t_1)$ is the subcurve source and $B(t_2)$ is its target. Note that as the point endpoints may only be approximated, the parameter range defining the subcurve may only be approximately known.

It is not possible to construct *x*-monotone subcurves directly. Instead, use the *Make_x_monotone_2* functor supplied by the traits class to subdivide a *Curve_2* object into *x*-monotone cubcurves.

Access Functions

<i>Curve_2</i>	<i>b.supporting_curve()</i>	returns the supporting Bézier curve of <i>b</i> .
<i>Point_2</i>	<i>b.source()</i>	returns the source point of <i>b</i> .
<i>Point_2</i>	<i>b.target()</i>	returns the target point of <i>b</i> .
<i>Point_2</i>	<i>b.left()</i>	returns the left (xy-lexicographically smaller) endpoint of <i>b</i> .
<i>Point_2</i>	<i>b.right()</i>	returns the right (xy-lexicographically smaller) endpoint of <i>b</i> .
<i>std::pair<double, double></i>	<i>b.parameter_range()</i>	return the approximate parameter range defining the sub-curve <i>b</i> .

CGAL::Arr_algebraic_segment_traits_2<Coefficient>

Definition

The traits class *Arr_algebraic_segment_traits_2<Coefficient>* is a model of the *ArrangementTraits_2* concept that handles planar algebraic curves of arbitrary degree, and *x*-monotone of such curves. A planar (real) *algebraic curve* is the vanishing set of a polynomial in two variables, that is, the curve is defined by the defining equation

$$f(x) := \sum_{i+j \leq n} a_{ij} x^i y^j = 0,$$

where *n* is the degree of the curve.

The traits class allows the construction of algebraic curves, by specifying their implicit equation. *x*-monotone and vertical segments of a curve can also be defined; unbounded curves and segments are supported. The template parameter *Coefficient* defines the innermost coefficient type of the polynomials. Currently, the types *leda::integer* and *CORE::BigInt* are supported as well as any instance of *CGAL::Sqrt_extension* that is instantiated with one of the integral types above.

```
#include <CGAL/Arr_algebraic_segment_traits_2.h>
```

Is Model for the Concepts

ArrangementTraits_2

Types

```
Arr_algebraic_segment_traits_2<Coefficient>:: enum Site_of_point POINT_IN_INTERIOR = 0, MIN_
ENDPOINT = -1, MAX_ENDPOINT = 1 ;
```

Value to specify whether a point should be in the interior of a segment, or its minimal point, or its maximal point in lexicographic order.

```
Arr_algebraic_segment_traits_2<Coefficient>:: Polynomial_2
```

the type for bivariate polynomials, with innermost coefficient type *Coefficient*. Constitutes a model of the concept *Polynomial_d* with two variables. (see page [page 253](#))

```
Arr_algebraic_segment_traits_2<Coefficient>:: Algebraic_kernel_1
```

model for the concept *AlgebraicKernel_1*

```
Arr_algebraic_segment_traits_2<Coefficient>:: Algebraic_real_1
```

represents coordinates of points. Typedef from *Algebraic_kernel_1::Algebraic_real_1*

Arr_algebraic_segment_traits_2<Coefficient>::Bound

Typedef from *Algebraic_kernel_1::Bound*

Class *Arr_algebraic_segment_traits_2<Coefficient>::Curve_2*

Models the *ArrangementTraits_2::Curve_2* concept. Represents algebraic curves. Internally, the type stores topological-geometric information about the particular curve. In order to use internal caching, instances should only be created using the *Construct_curve_2* functor of the traits class.

Polynomial_2 *C.polynomial()* returns the defining polynomial of the curve.

Class *Arr_algebraic_segment_traits_2<Coefficient>::Point_2*

Models the *ArrangementBasicTraits_2::Point_2* concept. Represents points in \mathbb{R}^2 . Intersection points of algebraic curves are in general non-rational, so we need a data structure that is capable of representing arbitrary points with algebraic coordinates.

The traits class represents algebraic coordinates by the type *Algebraic_real_1*, which is a model of the *AlgebraicReal_1* concept. A point p is stored by a triple $(x, cv, arcno)$, where x is the x -coordinate of a point, cv is an instance of *Curve_2* that contains the point, (and has no vertical line at x), and $arcno$ is an *int*, denoting that p is met as the $arcno$ -th point when shooting a vertical ray at x , starting from $-\infty$ (where counting starts with 0).

In addition to the methods listed below, the copy constructor and assignment operator for *Point_2* objects are also supported.

The functor *Construct_point_2* constructs *Point_2* instances.

Algebraic_real_1 $p.x()$ returns the x -coordinate of p .

Algebraic_real_1 $p.y()$ returns the y -coordinates of p .
Attention: As described above, points are not stored by their y -coordinate in *Algebraic_real_1* representation. In fact, this representation must be computed on demand, and might become quite costly for points defined by high-degree polynomials. Therefore, it is recommended to avoid to call this function as much as possible.

Curve_2 $p.curve()$ returns a *Curve_2* instance that p is part of.

int $p.arcno()$ returns the arc number of p .

std::pair<double,double>
 $p.to_double()$ returns double-approximations of the x - and y -coordinates.

Class `Arr_algebraic_segment_traits_2<Coefficient>::X_monotone_curve_2`

Models the *ArrangementBasicTraits_2::X_monotone_curve_2* concept. Represents terminal segments of an algebraic curves, that means vertical segments or x -monotone segments with no critical x -coordinate in the interior of their x -range. Terminal segments might either be bounded or unbounded. By definition, each interior point of a non-vertical segment has the same arc number (see the documentation of type *Point_2* above, which is called the *arc number* of the segment (note the arc number at the endpoints might differ). Such segments are represented internally by a 4-tuple $(p, q, cv, arco)$, where p and q are the endpoints, cv is the *supporting curve* that the segment belongs to, and $arco$ is the arc number of the segment.

Arbitrary (weakly) x -monotone segments are presented by a range of *X_monotone_curve_2* instances, whose union equals the segment. The functor *Construct_x_monotone_segment_2* allows their construction. To construct all (maximal) terminal segments of a curve, use the *Make_x_monotone_2* functor supplied by the traits class.

<i>Curve_2</i>	<i>s.curve()</i>	returns the supporting algebraic curve of <i>s</i> .
<i>bool</i>	<i>s.is_vertical()</i>	returns whether <i>s</i> is a vertical segment.
<i>bool</i>	<i>s.is_finite(CGAL::Arr_curve_end ce)</i>	returns whether <i>s</i> has a finite endpoint on the left (if <i>ce</i> == <i>CGAL::ARR_MIN_END</i>) or on the right (if <i>ce</i> == <i>CGAL::ARR_MAX_END</i>).
<i>Point_2</i>	<i>s.curve_end(CGAL::Arr_curve_end ce)</i>	returns the left or right endpoint of <i>s</i> for <i>ce</i> == <i>CGAL::ARR_MIN_END</i> and <i>ce</i> == <i>CGAL::ARR_MAX_END</i> . <i>Precondition:</i> (The corresponding curve end is finite)
<i>int</i>	<i>s.arco()</i>	returns the arc number of the segment. <i>Precondition:</i> (The segment is non-vertical)
<i>Algebraic_real_1</i>	<i>s.x()</i>	returns the x -coordinate of a vertical segment. <i>Precondition:</i> (The segment is vertical)

Object Creation Functors

Curves, points, and x -monotone segments are created by special functors. The functors are not default constructible; the only possibility to obtain them is by the corresponding accessing functions.

Class `Arr_algebraic_segment_traits_2<Coefficient>::Construct_curve_2`

<i>Curve_2</i>	<i>fo(Polynomial_2 p)</i>	Returns a <i>Curve_2</i> object that represents the curve defined by the polynomial <i>p</i>
----------------	----------------------------	--

<i>Curve_2</i>	<i>fo(std::string s)</i>	Returns a <i>Curve_2</i> object specified by <i>s</i> . The passed string represents the defining polynomial of the curve and must be given in a MAPLE-readable format using "x" as first and "y" as second variable, e.g., "(x^3*y-2*x)*(-6*x-y^3*x^6)" for integer coefficients, and "3/2*x*y^4-5/7*x^2+3/1" for rational coefficients.
----------------	---------------------------	---

Class Arr_algebraic_segment_traits_2<Coefficient>::Construct_point_2

<i>Point_2</i>	<i>fo(Algebraic_real_1 x, Curve_2 cv, int arcno)</i>	<p>Returns a <i>Point_2</i> object that represents the <i>arcno</i>-th point in the fiber of <i>cv</i> at <i>x</i>-coordinate <i>x</i>, counted from the bottom, starting with zero.</p> <p><i>Precondition:</i> (<i>cv</i> must not have a vertical line at <i>x</i>, and $0 \leq \text{arcno} < c$, where <i>c</i> is the number of points in the fiber of <i>cv</i> at <i>x</i>.)</p>
----------------	---	--

<i>Point_2</i>	<i>fo(Algebraic_real_1 x, X_monotone_curve_2 xcv)</i>	<p>Returns a <i>Point_2</i> object that represents the point on <i>xcv</i> at <i>x</i>-coordinate <i>x</i></p> <p><i>Precondition:</i> (<i>x</i> is in the <i>x</i>-range of <i>xcv</i>.)</p>
----------------	--	---

<i>Point_2</i>	<i>fo(Algebraic_real_1 x, Algebraic_real_1 y)</i>	Returns a <i>Point_2</i> object that represents (<i>x</i> , <i>y</i>)
----------------	--	---

<i>Point_2</i>	<i>fo(Coefficient x, Coefficient y)</i>	Returns a <i>Point_2</i> object that represents (<i>x</i> , <i>y</i>)
----------------	--	---

<i>Point_2</i>	<i>fo(Bound x, Bound y)</i>	Returns a <i>Point_2</i> object that represents (<i>x</i> , <i>y</i>)
----------------	------------------------------	---

<i>Point_2</i>	<i>fo(int x, int y)</i>	Returns a <i>Point_2</i> object that represents (<i>x</i> , <i>y</i>)
----------------	--------------------------	---

Class Arr_algebraic_segment_traits_2<Coefficient>::Construct_x_monotone_segment_2

template<class OutputIterator>

<i>OutputIterator</i>	<i>fo(Curve_2 cv, Point_2 end_min, Point_2 end_max, OutputIterator out)</i>
-----------------------	--

Writes a sequence of *X_monotone_curve_2* objects into *out*. These segments form an *x*-monotone (or vertical) segment of the curve *cv* that starts in *end_min*, and end in *end_max*.

Precondition: (*end_min* must have a unique *x*-monotone segment to its right, or *end_max* must have a unique *x*-monotone segment to its left. Furthermore, *end_min* and *end_max* must be connected by a *x*-monotone segment of *cv*)

template<class OutputIterator>

OutputIterator *fo(Curve_2 cv, Point_2 p, Site_of_point site_of_p, OutputIterator out)*

Writes a sequence of *X_monotone_curve_2* objects into *out*. These segments form an *x*-monotone (or vertical) segment of the curve *cv*.

If *site_of_p*==*POINT_IN_INTERIOR*, the maximal segment is returned that contains *p* in its interior.

If *site_of_p*==*MIN_ENDPOINT*, the maximal segment is returned that contains *p* as its left endpoint.

If *site_of_p*==*MAX_ENDPOINT*, the maximal segment is returned that contains *p* as its left endpoint.

Precondition: (If *site_of_p*==*POINT_IN_INTERIOR*, *p* must be an interior point of an *x*-monotone or a vertical segment.

If *site_of_p*==*MIN_ENDPOINT*, *p* must either have a unique *x*-monotone segment to the right, or a vertical segment from *p* upwards. If *site_of_p*==*MAX_ENDPOINT*, *p* must either have a unique *x*-monotone segment to the left, or a vertical segment from *p* downwards.)

template<class OutputIterator>

OutputIterator *fo(Point_2 p, Point_2 q, OutputIterator out)*

Writes a sequence of *X_monotone_curve_2* objects into *out*. These segments form a straight-line segment connecting the points *p* and *q*. If *p* and *q* share the same *x*-coordinate, the constructed vertical segment consists of only one *X_monotone_curve_2* object and can be computed efficiently.

In the non-vertical case, the construction is only possible if *p* and *q* have both rational *x*- and *y*-coordinates.

Precondition: (*p* must not be equal to *q*.)

CGAL::Arr_curve_data_traits_2<Tr,XData,Mrg,CData,Cnv>

Definition

The class *Arr_curve_data_traits_2*<*Tr*,*XData*,*Mrg*,*CData*,*Cnv*> is a model of the *ArrangementTraits_2* concept and serves as a decorator class that allows the extension of the curves defined by the base traits-class (the *Tr* parameter), which serves as a geometric traits-class (a model of the *ArrangementTraits_2* concept), with extraneous (non-geometric) data fields.

The traits class inherits its point type from *Traits::Point_2*, and defines an extended *Curve_2* and *X_monotone_curve_2* types, as detailed below.

Each *Curve_2* object is associated with a single data field of type *CData*, and each *X_monotone_curve_2* object is associated with a single data field of type *XData*. When a curve is subdivided into *x*-monotone subcurves, its data field is converted using the conversion functor, which is specified by the *Cnv* template-parameter, and the resulting objects is copied to all *X_monotone_curve_2* objects induced by this curve. The conversion functor should provide an operator with the following prototype:

```
XData operator() (const CData& d) const;
```

By default, the two data types are the same, so the conversion operator is trivial:

```
CData = XData
```

```
Cnv = _Default_convert_functor<CData,XData>
```

In case two (or more) *x*-monotone curves overlap, their data fields are merged to a single field, using the merge functor, which is specified by the *Mrg* template-parameter. This functor should provide an operator with the following prototype:

```
XData operator() (const XData& d1, const XData& d2) const;
```

which returns a single data object that represents the merged data field of *d1* and *d2*. The *x*-monotone curve that represents the overlap is associated with the output of this functor.

```
#include <CGAL/Arr_curve_data_traits_2.h>
```

```
the base x-monotone curve curve.
```

<i>typedef Mrg</i>	<i>Merge;</i>	the merge functor.
<i>typedef Cnv</i>	<i>Convert;</i>	the conversion functor.
<i>typedef CData</i>	<i>Curve_data;</i>	the type of data associated with curves.
<i>typedef XData</i>	<i>X_monotone_curve_data;</i>	the type of data associated with <i>x</i> -monotone curves.

Inherits From

Base_traits_2

Class **Arr_curve_data_traits_2<Tr,XData,Mrg,CData,Cnv>::Curve_2**

The *Curve_2* class nested within the curve-data traits extends the *Base_traits_2::Curve_2* type with an extra data field of type *Data*.

Inherits From

Base_curve_2

Creation

Arr_curve_data_traits_2<Tr,XData,Mrg,CData,Cnv>::Curve_2 cv;

default constructor.

Arr_curve_data_traits_2<Tr,XData,Mrg,CData,Cnv>::Curve_2 cv(Base_curve_2 base);

constructs curve from the given *base* curve with uninitialized data field.

Arr_curve_data_traits_2<Tr,XData,Mrg,CData,Cnv>::Curve_2 cv(Base_curve_2 base, Data data);

constructs curve from the given *base* curve with an attached *data* field.

Access Functions

Curve_data *cv.data()* returns the data field (a non-const version, which returns a reference to the data object, is also available).

void *cv.set_data(Curve_data data)*

sets the data field.

Class Arr_curve_data_traits_2<Tr,XData,Mrg,CData,Cnv>::X_monotone_curve_2

The *X_monotone_curve_2* class nested within the curve-data traits extends the *Base_traits_2::X_monotone_curve_2* type with an extra data field.

Inherits From

Base_x_monotone_curve_2

Creation

Arr_curve_data_traits_2<Tr,XData,Mrg,CData,Cnv>::X_monotone_curve_2 *xcv*;

default constructor.

Arr_curve_data_traits_2<Tr,XData,Mrg,CData,Cnv>::X_monotone_curve_2 *xcv*(*Base_x_monotone_curve_2* *base*)

constructs an *x*-monotone curve from the given *base* curve with uninitialized data field.

Arr_curve_data_traits_2<Tr,XData,Mrg,CData,Cnv>::X_monotone_curve_2 *xcv*(*Base_x_monotone_curve_2* *base*,
X_monotone_curve_data *data*)

constructs an *x*-monotone curve from the given *base x*-monotone curve with an attached *data* field.

Access Functions

X_monotone_curve_data

xcv.data() returns the field (a non-const version, which returns a reference to the data object, is also available).

void *xcv.set_data*(*X_monotone_curve_data* *data*)

sets the data field.

CGAL::Arr_consolidated_curve_data_traits_2<Traits,Data>

Definition

The class *Arr_consolidated_curve_data_traits_2<Traits,Data>* is a model of the concept *ArrangementTraits_2*, and serves as a decorator class that enables the extension of the curve type defined by the *Traits* parameter. The traits class inherits its point type from *Traits::Point_2*, and defines the types *Curve_2* and *X_monotone_curve_2* extended with extraneous data fields of type *Data*.

Each *Curve_2* object is associated with a single data field of type *Data*, and each *X_monotone_curve_2* object is associated with a set of unique data objects. When a curve is subdivided into *x*-monotone subcurves, all resulting subcurves are associated with a list containing a single data object, copied from the inducing curve. When an *x*-monotone curve is split, its data set is duplicated, and inserted into the sets of both resulting subcurves. In case two (or more) *x*-monotone curves overlap, their data sets are consolidated, and are inserted into the set of the *x*-monotone curve that represents the overlap.

```
#include <CGAL/Arr_consolidated_curve_data_traits_2.h>
```

Is Model for the Concepts

ArrangementTraits_2

Inherits From

```
Arr_curve_data_traits_2<Traits,
    _Unique_list<Data>,
    _Consolidate_unique_lists<Data>,
    Data>
```

Types

```
typedef Traits          Base_traits_2;          the base traits-class.
typedef typename Base_traits_2::Curve_2

                                Base_curve_2;    the base curve.
typedef typename Base_traits_2::X_monotone_curve_2

                                Base_x_monotone_curve_2;

                                the base x-monotone curve curve.
```

```
Arr_consolidated_curve_data_traits_2<Traits,Data>:: typedef Data_container
```

a set of data objects that is associated with an *x*-monotone curve.

```
Arr_consolidated_curve_data_traits_2<Traits,Data>:: typedef Data_iterator
```

a non-mutable iterator for the data objects in the data container.

Class `Arr_consolidated_curve_data_traits_2<Traits,Data>::Data_container`

The *Data_container* class nested within the consolidated curve-data traits and associated with the *Traits::X_monotone_curve_2* type is maintained as a list with unique data objects. This representation is simple and efficient in terms of memory consumption. It also requires that the *Data* class supports only the equality operator. Note however that most set operations require linear time.

Creation

Arr_consolidated_curve_data_traits_2<Traits,Data>::Data_container dset;

default constructor.

Arr_consolidated_curve_data_traits_2<Traits,Data>::Data_container dset(Data data);

constructs set containing a single *data* object.

Access Functions

<i>std::size_t</i>	<i>dset.size()</i>	returns the number of data objects in the set.
<i>Data_iterator</i>	<i>dset.begin()</i>	returns an iterator pointing to the first data object.
<i>Data_iterator</i>	<i>dset.end()</i>	returns a past-the-end iterator for the data objects.
<i>Data</i>	<i>dset.front()</i>	returns the first data object inserted into the set. <i>Precondition:</i> The number of data objects is not 0.
<i>Data</i>	<i>dset.back()</i>	returns the last data object inserted into the set. <i>Precondition:</i> The number of data objects is not 0.

Predicates

<i>bool</i>	<i>dset == Data_container other</i>	check if the two sets contain the same data objects (regardless of order).
<i>Data_iterator</i>	<i>dset.find(Data data)</i>	find the given <i>data</i> object in the set and returns an iterator for this object, or <i>end()</i> if it is not found.

Modifiers

<i>bool</i>	<i>dset.insert(Data data)</i>	inserts the given <i>data</i> object into the set. Returns <i>true</i> on success, or <i>false</i> if the set already contains the object.
-------------	--------------------------------	--

<i>bool</i>	<i>dset.erase(Data data)</i>	erases the given <i>data</i> object from the set. Returns <i>true</i> on success, or <i>false</i> if the set does not contain the object.
<i>void</i>	<i>dset.clear()</i>	clears the set.

ArrangementInputFormatter

A model for the ArrangementInputFormatter concept supports a set of functions that enable reading an arrangement from an input stream using a specific format.

Types

ArrangementInputFormatter::Arrangement_2 the type of arrangement to input.

typedef typename Arrangement_2::Point_2

Point_2; the point type.

typedef typename Arrangement_2::X_monotone_curve_2

X_monotone_curve_2;

the *x*-monotone curve type.

typedef typename Arrangement_2::Size

Size;

typedef typename Arrangement_2::Vertex_handle

Vertex_handle;

typedef typename Arrangement_2::Halfedge_handle

Halfedge_handle;

typedef typename Arrangement_2::Face_handle

Face_handle;

Creation

ArrangementInputFormatter inf; default constructor.

ArrangementInputFormatter inf(std::istream& is);

constructs a formatter that reads from *is*.

void inf.set_in(std::istream& is)

directs *inf* to read from *is*.

Access Functions

std::istream& inf.in()

returns the stream that *inf* reads from.

Precondition: *inf* is directed to a valid output stream.

Formatted Input Functions

<i>void</i>	<i>inf.read_arrangement_begin()</i>	reads a message indicating the beginning of the arrangement.
<i>void</i>	<i>inf.read_arrangement_end()</i>	reads a message indicating the end of the arrangement.
<i>Size</i>	<i>inf.read_size(const char *label = NULL)</i>	reads a size value, which is supposed to be preceeded by the given label.
<i>void</i>	<i>inf.read_vertices_begin()</i>	reads a message indicating the beginning of the vertex records.
<i>void</i>	<i>inf.read_vertices_end()</i>	reads a message indicating the end of the vertex records.
<i>void</i>	<i>inf.read_edges_begin()</i>	reads a message indicating the beginning of the edge records.
<i>void</i>	<i>inf.read_edges_end()</i>	reads a message indicating the end of the edge records.
<i>void</i>	<i>inf.read_faces_begin()</i>	reads a message indicating the beginning of the face records.
<i>void</i>	<i>inf.read_faces_end()</i>	reads a message indicating the end of the face records.
<i>void</i>	<i>inf.read_vertex_begin()</i>	reads a message indicating the beginning of a single vertex record.
<i>void</i>	<i>inf.read_vertex_end()</i>	reads a message indicating the end of a single vertex record.
<i>std::size_t</i>	<i>inf.read_vertex_index()</i>	reads and returns a vertex index.
<i>void</i>	<i>inf.read_point(Point_2& p)</i>	reads a point.

<i>void</i>	<i>inf.read_vertex_data(Vertex_handle v)</i>	reads an auxiliary vertex-data object and associates it with the vertex <i>v</i> .
<i>void</i>	<i>inf.read_edge_begin()</i>	reads a message indicating the beginning of a single edge record.
<i>void</i>	<i>inf.read_edge_end()</i>	reads a message indicating the end of a single edge record.
<i>std::size_t</i>	<i>inf.read_halfedge_index()</i>	reads and returns halfedge index.
<i>void</i>	<i>inf.read_x_monotone_curve(X_monotone_curve_2& c)</i>	reads an <i>x</i> -monotone curve.
<i>void</i>	<i>inf.read_halfedge_data(Halfedge_handle he)</i>	reads an auxiliary halfedge-data object and associates it with the halfedge <i>he</i> .
<i>void</i>	<i>inf.read_face_begin()</i>	reads a message indicating the beginning of a single face record.
<i>void</i>	<i>inf.read_face_end()</i>	reads a message indicating the end of a single face record.
<i>void</i>	<i>inf.read_outer_ccb_begin()</i>	reads a message indicating the beginning of the outer CCB of the current face.
<i>void</i>	<i>inf.read_outer_ccb_end()</i>	reads a message indicating the end of the outer CCB of the current face.
<i>void</i>	<i>inf.read_holes_begin()</i>	reads a message indicating the beginning of the container of holes inside the current face.
<i>void</i>	<i>inf.read_holes_end()</i>	reads a message indicating the end of the container of holes inside the current face.
<i>void</i>	<i>inf.read_inner_ccb_begin()</i>	reads a message indicating the beginning of an inner CCB of the current face.

<i>void</i>	<i>inf.read_inner_ccb_end()</i>	reads a message indicating the end of an inner CCB of the current face.
<i>void</i>	<i>inf.read_ccb_halfedges_begin()</i>	reads a message indicating the beginning a connected component boundary.
<i>void</i>	<i>inf.read_ccb_halfedges_end()</i>	reads a message indicating the end of a connected component boundary.
<i>void</i>	<i>inf.read_isolated_vertices_begin()</i>	reads a message indicating the beginning of the container of isolated vertices inside the current face.
<i>void</i>	<i>inf.read_isolated_vertices_end()</i>	reads a message indicating the end of the container of isolated vertices inside the current face.
<i>void</i>	<i>inf.read_face_data(Face_handle f)</i>	reads an auxiliary face-data object and associates it with the face <i>f</i> .

ArrangementOutputFormatter

A model for the ArrangementOutputFormatter concept supports a set of functions that enable writing an arrangement to an output stream using a specific format.

Types

ArrangementOutputFormatter::Arrangement_2

the type of arrangement to output.

typedef typename Arrangement_2::Point_2

Point_2; the point type.

typedef typename Arrangement_2::X_monotone_curve_2

X_monotone_curve_2;

the *x*-monotone curve type.

typedef typename Arrangement_2::Size

Size;

typedef typename Arrangement_2::Vertex_const_handle

Vertex_const_handle;

typedef typename Arrangement_2::Halfedge_const_handle

Halfedge_const_handle;

typedef typename Arrangement_2::Face_const_handle

Face_const_handle;

Creation

ArrangementOutputFormatter outf; default constructor.

ArrangementOutputFormatter outf(std::ostream& os);

constructs a formatter that writes to *os*.

void outf.set_out(std::ostream& os)

directs *outf* to write to *os*.

Access Functions

std::ostream& *outf.out()* returns the stream that *outf* writes to.
Precondition: outf is directed to a valid output stream.

Formatted Output Functions

void *outf.write_arrangement_begin()*
writes a message indicating the beginning of the arrangement.

void *outf.write_arrangement_end()*
writes a message indicating the end of the arrangement.

void *outf.write_size(const char *label, Size size)*
writes a size value, preceeded by a given label.

void *outf.write_vertices_begin()*
writes a message indicating the beginning of the vertex records.

void *outf.write_vertices_end()*
writes a message indicating the end of the vertex records.

void *outf.write_edges_begin()*
writes a message indicating the beginning of the edge records.

void *outf.write_edges_end()*
writes a message indicating the end of the edge records.

void *outf.write_faces_begin()*
writes a message indicating the beginning of the face records.

void *outf.write_faces_end()*
writes a message indicating the end of the face records.

void *outf.write_vertex_begin()*
writes a message indicating the beginning of a single vertex record.

void *outf.write_vertex_end()*
writes a message indicating the end of a single vertex record.

<i>void</i>	<i>outf.write_vertex_index(std::size_t idx)</i>	writes a vertex index.
<i>void</i>	<i>outf.write_point(Point_2 p)</i>	writes a point.
<i>void</i>	<i>outf.write_vertex_data(Vertex_const_handle v)</i>	writes the auxiliary data associated with the vertex.
<i>void</i>	<i>outf.write_edge_begin()</i>	writes a message indicating the beginning of a single edge record.
<i>void</i>	<i>outf.write_edge_end()</i>	writes a message indicating the end of a single edge record.
<i>void</i>	<i>outf.write_halfedge_index(std::size_t idx)</i>	writes a halfedge index.
<i>void</i>	<i>outf.write_x_monotone_curve(X_monotone_curve_2 c)</i>	writes an <i>x</i> -monotone curve.
<i>void</i>	<i>outf.write_halfedge_data(Halfedge_const_handle he)</i>	writes the auxiliary data associated with the halfedge.
<i>void</i>	<i>outf.write_face_begin()</i>	writes a message indicating the beginning of a single face record.
<i>void</i>	<i>outf.write_face_end()</i>	writes a message indicating the end of a single face record.
<i>void</i>	<i>outf.write_outer_ccb_begin()</i>	writes a message indicating the beginning of the outer CCB of the current face.
<i>void</i>	<i>outf.write_outer_ccb_end()</i>	writes a message indicating the end of the outer CCB of the current face.

<i>void</i>	<i>outf.write_holes_begin()</i>	writes a message indicating the beginning of the container of holes inside the current face.
<i>void</i>	<i>outf.write_holes_end()</i>	writes a message indicating the end of the container of holes inside the current face.
<i>void</i>	<i>outf.write_ccb_halfedges_begin()</i>	writes a message indicating the beginning a connected component's boundary.
<i>void</i>	<i>outf.write_ccb_halfedges_end()</i>	writes a message indicating the end of a connected component's boundary.
<i>void</i>	<i>outf.write_isolated_vertices_begin()</i>	writes a message indicating the beginning of the container of isolated vertices inside the current face.
<i>void</i>	<i>outf.write_isolated_vertices_end()</i>	writes a message indicating the end of the container of isolated vertices inside the current face.
<i>void</i>	<i>outf.write_face_data(Face_const_handle f)</i>	writes the auxiliary data associated with the face.

Arr_face_extended_text_formatter<Arrangement> (page [2197](#))

Arr_extended_dcel_text_formatter<Arrangement> (page [2198](#))

CGAL::Arr_text_formatter<Arrangement>

Definition

Arr_text_formatter<Arrangement> defines the format of an arrangement in an input or output stream (typically a file stream), thus enabling reading and writing an *Arrangement* instance using a simple text format. The arrangement is assumed to store no auxiliary data with its DCEL records (and if there are such records they will not be written or read by the formatter).

The *Arr_text_formatter<Arrangement>* class assumes that the nested *Point_2* and the *Curve_2* types defined by the *Arrangement* template-parameter can both be written to an input stream using the << operator and read from an input stream using the >> operator.

```
#include <CGAL/IO/Arr_text_formatter.h>

ArrangementPointLocation_2

Definition

A model of the ArrangementPointLocation_2 concept can be attached to an *Arrangement_2* instance and answer point-location queries on this arrangement. Namely, given a *Arrangement_2::Point_2* object, representing a point in the plane, it returns the arrangement cell containing it. In the general case, the query point is contained inside an arrangement face, but in degenerate situations it may lie on an edge or coincide with an arrangement vertex.

Types

ArrangementPointLocation_2::Arrangement_2

the associated arrangement type.

ArrangementPointLocation_2::Point_2

equivalent to *Arrangement_2::Point_2*.

Creation

ArrangementPointLocation_2 pl;

default constructor.

ArrangementPointLocation_2 pl(Arrangement_2 arr);

constructs a point-location object *pl* attached to the given arrangement *arr*.

Query Functions

Object

pl.locate(Point_2 q)

locates the arrangement cell that contains the query point *q* and returns a handle for this cell. The function returns an *Object* instance that wraps either of the following types:

- *Arrangement_2::Face_const_handle*, in case *q* is contained inside an arrangement face;
- *Arrangement_2::Halfedge_const_handle*, in case *q* lies on an arrangement edge;
- *Arrangement_2::Vertex_const_handle*, in case *q* coincides with an arrangement vertex.

Precondition: *pl* is attached to a valid arrangement instance.

Operations

void *pl.attach(Arrangement_2 arr)*

attaches *pl* to the given arrangement *arr*.

void *pl.detach()*

detaches *pl* from the arrangement it is currently attached to.

ArrangementVerticalRayShoot_2

Definition

A model of the `ArrangementVerticalRayShoot_2` concept can be attached to an `Arrangement_2` instance and answer vertical ray-shooting queries on this arrangement. Namely, given a `Arrangement_2::Point_2` object, representing a point in the plane, it returns the arrangement feature (edge or vertex) that lies strictly above it (or below it). By “strictly” we mean that if the query point lies on an arrangement edge (or on an arrangement vertex) this edge will *not* be the query result, but the feature lying above or below it. (An exception to this rule is the degenerate situation where the query point lies in the interior of a vertical edge.) Note that it may happen that the query point lies above the upper envelope (or below the lower envelope) of the arrangement, so that the vertical ray emanating from it may go to infinity without hitting any arrangement feature on its way. In this case the unbounded face is returned.

Types

`ArrangementVerticalRayShoot_2::Arrangement_2`

the associated arrangement type.

`ArrangementVerticalRayShoot_2::Point_2`

equivalent to `Arrangement_2::Point_2`.

Creation

`ArrangementVerticalRayShoot_2 rs;`

default constructor.

`ArrangementVerticalRayShoot_2 rs(Arrangement_2 arr);`

constructs a ray-shooting object `rs` attached to the given arrangement `arr`.

Query Functions

Object

`rs.ray_shoot_up(Point_2 q)`

locates the arrangement feature that is first hit by an upward-directed vertical ray emanating from the query point q , and returns a handle for this feature. The function returns an *Object* instance that is a wrapper for one of the following types:

- `Arrangement_2::Halfedge_const_handle`, in case the vertical ray hits an arrangement edge;
- `Arrangement_2::Vertex_const_handle`, in case the vertical ray hits an arrangement vertex.
- `Arrangement_2::Face_const_handle` for the unbounded arrangement face, in case q lies above the upper envelope of the arrangement.

Precondition: `rs` is attached to a valid arrangement instance.

Object

rs.ray_shoot_down(Point_2 q)

locates the arrangement feature that is first hit by a downward-directed vertical ray emanating from the query point q , and returns a handle for this feature. The function returns an *Object* instance that is a wrapper for one of the following types:

- *Arrangement_2::Halfedge_const_handle*, in case the vertical ray hits an arrangement edge;
- *Arrangement_2::Vertex_const_handle*, in case the vertical ray hits an arrangement vertex.
- *Arrangement_2::Face_const_handle* for the unbounded arrangement face, in case q lies below the lower envelope of the arrangement.

Precondition: *rs* is attached to a valid arrangement instance.

Operations

void

rs.attach(Arrangement_2 arr)

attaches *rs* to the given arrangement *arr*.

void

rs.detach()

detaches *rs* from the arrangement it is currently attached to.

Arr_trapezoid_ric_point_location<Arrangement>

Arr_landmarks_point_location<Arrangement,Generator>

CGAL::Arr_naive_point_location<Arrangement>

Definition

The *Arr_naive_point_location<Arrangement>* class implements a naive algorithm that traverses all the vertices and halfedges in the arrangement in search for an answer to a point-location query. The query time is therefore linear in the complexity of the arrangement. Naturally, this point-location strategy could turn into a heavy time-consuming process when applied to dense arrangements.

```
#include <CGAL/Arr_naive_point_location.h>
```

Is Model for the Concepts

ArrangementPointLocation_2
ArrangementVerticalRayShoot_2

CGAL::Arr_walk_along_line_point_location<Arrangement>

Definition

The *Arr_walk_along_line_point_location<Arrangement>* class implements a very simple point-location (and vertical ray-shooting) strategy that improves the naïve one. The algorithm considers an imaginary vertical ray emanating from the query point, and simulates a walk along the zone of this ray, starting from the unbounded face until reaching the query point. In dense arrangements this walk can considerably reduce the number of traversed arrangement edges, with respect to the naïve algorithm.

The walk-along-a-line point-location object (just like the naïve one) does not use any auxiliary data structures. Thus, attaching it to an existing arrangement takes constant time, and any ongoing updates to this arrangement do not affect the point-location object. It is therefore recommended to use the “walk” point-location strategy for arrangements that are constantly changing, especially if the number of issued queries is not large.

```
#include <CGAL/Arr_walk_along_line_point_location.h>
```

Is Model for the Concepts

ArrangementPointLocation_2
ArrangementVerticalRayShoot_2

CGAL::Arr_trapezoid_ric_point_location<Arrangement>

Definition

The *Arr_trapezoid_ric_point_location<Arrangement>* class implements the incremental randomized algorithm introduced by Mulmuley [Mul90] as presented by Seidel [Sei91] (see also [dBvKOS00, Chapter 6]). It subdivides each arrangement face to pseudo-trapezoidal cells, each of constant complexity, and constructs and maintains a search structure on top of these cells, such that each query can be answered in $O(\log n)$ time, where n is the complexity of the arrangement.

Constructing the search structures takes $O(n \log n)$ time, such that attaching a trapezoidal point-location object to an existing arrangement may incur some overhead in running times. In addition, the point-location object needs to keep its auxiliary data structures up-to-date as the arrangement goes through structural changes. It is therefore recommended to use this point-location strategy for static arrangements (or arrangements that do not alter frequently), and when the number of issued queries is relatively large.

```
#include <CGAL/Arr_trapezoid_ric_point_location.h>
```

Is Model for the Concepts

ArrangementPointLocation_2
ArrangementVerticalRayShoot_2

CGAL::Arr_landmarks_point_location<Arrangement,Generator>

The *Arr_landmarks_point_location*<*Arrangement*,*Generator*> class implements a Jump & Walk algorithm, where special points, referred to as “landmarks”, are chosen in a preprocessing stage, their place in the arrangement is found, and they are inserted into a data-structure that enables efficient nearest-neighbor search (a KD-tree). Given a query point, the nearest landmark is located and a “walk” strategy is applied from the landmark to the query point.

There are various strategies to select the landmark set in the arrangement, where the strategy is determined by the *Generator* template parameter. The following landmark-generator classes are available:

Arr_landmarks_vertices_generator — The arrangement vertices are used as the landmarks set.

Arr_random_landmarks_generator — n random points in the bounding box of the arrangement are chosen as the landmarks set.

Arr_halton_landmarks_generator — n Halton points in the bounding box of the arrangement are chosen as the landmarks set.

Arr_middle_edges_landmarks_generator — The midpoint of each arrangement edge is computed, and the resulting set of points is used as the landmarks set. This generator can be applied only for arrangements of line segments.

Arr_grid_landmarks_generator — A set of n landmarks are chosen on a $\lceil\sqrt{n}\rceil \times \lceil\sqrt{n}\rceil$ grid that covers the bounding box of the arrangement.

The *Arr_landmarks_vertices_generator* class is the default generator and used if no *Generator* parameter is specified.

It is recommended to use the landmarks point-location strategy when the application frequently issues point-location queries on a rather static arrangement that the changes applied to it are mainly insertions of curves and not deletions of them.

```
#include <CGAL/Arr_landmarks_point_location.h>
```

Is Model for the Concepts

ArrangementPointLocation_2

ArrangementVerticalRayShoot_2

CGAL::locate

Definition

The function *locate* performs a batched point-location operation on a given arrangement. It accepts a range of query points, and locates each point in the arrangement. The query results are returned through the output iterator. Each result is given as a pair of the query point and an object representing the arrangement feature that contains it, namely an *Object* that may be either *Face_const_handle*, *Halfedge_const_handle*, or *Vertex_const_handle*. The resulting pairs in the output sequence are sorted in increasing *xy*-lexicographical order of the query points. The function returns a past-the-end iterator of the output sequence.

```
#include <CGAL/Arr_batched_point_location.h>
```

```
template<typename Traits, typename Dcel, typename PointsIterator, typename OutputIterator>
OutputIterator      locate( Arrangement_2<Traits,Dcel> arr,
                           PointsIterator points_begin,
                           PointsIterator points_end,
                           OutputIterator oi)
```

Requirements

- *InputIterator::value_type* must be *Traits::Point_2*.
- *OutputIterator::value_type* must be *std::pair<Traits::Point_2, Object>*.

CGAL::decompose

Definition

The function *decompose* produces the symbolic vertical decomposition of a given arrangement, performing a batched vertical ray-shooting query from all arrangement vertices, such that every vertex is associated with a pair of objects, one corresponds to the arrangement feature that lies below it, and the other corresponds to the feature that lies above it. The output of this function can be readily used for inserting vertical walls and physically decomposing the arrangement into pseudo-trapezoids. To do this, it is convenient to process the vertices in an ascending *xy*-lexicographic order. The visible objects are therefore returned through an output iterator, which pairs each finite arrangement vertex with the two features it “sees”, such that the vertices are given in ascending *xy*-lexicographic order.

```
#include <CGAL/Arr_vertical_decomposition_2.h>
```

```
template<typename Traits, typename Dcel, typename OutputIterator>
OutputIterator  decompose( Arrangement_2<Traits,Dcel> arr, OutputIterator oi)
```

Produces the symbolic vertical decomposition of the *arr* arrangement. More precisely, it performs a batched vertical ray-shooting query from all arrangement vertices, such that every vertex is associated with a pair of objects, one corresponding to the arrangement feature that lies below it, while the other corresponds to the feature that lies above it. The query results are returned through the output iterator, which pairs each finite arrangement vertex with a pair of *Objects*, the first represents the feature below the vertex, and the second represents the feature that lies above it. Each *Object* may be one of the following:

- *Halfedge_const_handle*, if the vertex is located above (or below) an edge. The given halfedge is always directed from right to left. In case there is no concrete edge below (or above) the vertex, and the arrangement is unbounded, then the object returned is a *fictitious* halfedge.
- *Face_const_handle*, in case there is no edge below (or above) the vertex, and the arrangement is bounded.
- *Vertex_const_handle*, in case the vertex is located vertically above (or below) another arrangement vertex.
- An empty object, in case the vertex is the top end-vertex of a vertical edge, we define there is no feature below it. Similarly, if it is the bottom end-vertex of a vertical edge, we define that there is no feature above it.

The function returns a past-the-end iterator for its output sequence.

Requirements

OutputIterator::value_type must be *pair<Arrangement_2::Vertex_const_handle, pair<Object, Object> >*.

CGAL::Arr_observer<Arrangement>

Definition

Arr_observer<Arrangement> serves as an abstract base class for all observer classes that are attached to an arrangement instance of type *Arrangement* and receive notifications from the arrangement. This base class handles the attachment of the observer to a given arrangement instance or to the detachment of the observer from this arrangement instance. It also gives a default empty implementation to all notification functions that are invoked by the arrangement to notify the observer on local or global changes it undergoes. The notification functions are all virtual functions, so they can be overridden by the concrete observer classes that inherit from *Arr_observer<Arrangement>*.

In order to implement a concrete arrangement observer-class, one simply needs to derive from *Arr_observer<Arrangement>* and override the relevant notification functions. For example, if only face-split events are of interest, it is sufficient to override just *before_split_face()* (or just *after_split_face()*).

```
#include <CGAL/Arr_observer.h>
```

Types

Arr_observer<Arrangement>::Arrangement_2 the type of the associated arrangement.

```
typedef typename Arrangement_2::Point_2
```

Point_2; the point type.

```
typedef typename Arrangement_2::X_monotone_curve_2
```

X_monotone_curve_2;

the x-monotone curve type.

```
typedef typename Arrangement_2::Vertex_handle
```

Vertex_handle;

```
typedef typename Arrangement_2::Halfedge_handle
```

Halfedge_handle;

```
typedef typename Arrangement_2::Face_handle
```

Face_handle;

```
typedef typename Arrangement_2::Ccb_halfedge_circulator
```

Ccb_halfedge_circulator;

represents the boundary of a connected component (CCB).
In particular, holes are represented by a circulator for their outer CCB.

Creation

Arr_observer<Arrangement> *obs*; constructs an observer that is unattached to any arrangement instance.

Arr_observer<Arrangement> *obs*(*Arrangement_2* & *arr*);

 constructs an observer and attaches it to the given arrangement *arr*.

Modifiers

void *obs.attach*(*Arrangement_2* & *arr*)

 attaches the observer to the given arrangement *arr*.

void *obs.detach*() detaches the observer from its arrangement.

Notifications on Global Arrangement Operations

virtual void *obs.before_assign*(*Arrangement_2* *arr*)

 issued just before the attached arrangement is assigned with the contents of another arrangement *arr*.

virtual void *obs.after_assign*() issued immediately after the attached arrangement has been assigned with the contents of another arrangement.

virtual void *obs.before_clear*() issued just before the attached arrangement is cleared.
virtual void *obs.after_clear*(*Face_handle* *uf*)

 issued immediately after the attached arrangement has been cleared, so it now consists only of a the unbounded face *uf*.

virtual void *obs.before_global_change*()

 issued just before a global function starts to modify the attached arrangement. It is guaranteed that no queries (especially no point-location queries) are issued until the termination of the global function is indicated by *after_global_change*().

virtual void *obs.after_global_change*()

 issued immediately after a global function has stopped modifying the attached arrangement.

Notifications on Attachment or Detachment

<i>virtual void</i>	<i>obs.before_attach(Arrangement_2 arr)</i>	issued just before the observer is attached to the arrangement instance <i>arr</i> .
<i>virtual void</i>	<i>obs.after_attach()</i>	issued immediately after the observer has been attached to an arrangement instance.
<i>virtual void</i>	<i>obs.before_detach()</i>	issued just before the observer is detached from its arrangement instance.
<i>virtual void</i>	<i>obs.after_detach()</i>	issued immediately after the observer has been detached from its arrangement instance.

Notifications on Local Changes in the Arrangement

<i>virtual void</i>	<i>obs.before_create_vertex(Point_2 p)</i>	issued just before a new vertex that corresponds to the point <i>p</i> is created.
<i>virtual void</i>	<i>obs.after_create_vertex(Vertex_handle v)</i>	issued immediately after a new vertex <i>v</i> has been created. Note that the vertex still has no incident edges and is not connected to any other vertex.
<i>virtual void</i>	<i>obs.before_create_boundary_vertex(X_monotone_curve_2 cv, Arr_curve_end ind, Arr_parameter_space ps_x, Arr_parameter_space ps_y)</i>	issued just before a new vertex at infinity is created, <i>cv</i> is the curve incident to the surface boundary, <i>ind</i> is the relevant curve-end, <i>ps_x</i> is the boundary condition of the vertex in <i>x</i> and <i>ps_y</i> is the boundary condition of the vertex in <i>y</i> .
<i>virtual void</i>	<i>obs.after_create_boundary_vertex(Vertex_handle v)</i>	issued immediately after a new vertex <i>v</i> has been created. Note that the vertex still has no incident edges and is not connected to any other vertex.
<i>virtual void</i>	<i>obs.before_create_edge(X_monotone_curve_2 c, Vertex_handle v1, Vertex_handle v2)</i>	issued just before a new edge that corresponds to the <i>x</i> -monotone curve <i>c</i> and connects the vertices <i>v1</i> and <i>v2</i> is created.
<i>virtual void</i>	<i>obs.after_create_edge(Halfedge_handle e)</i>	issued immediately after a new edge <i>e</i> has been created. The halfedge that is sent to this function is always directed from <i>v1</i> to <i>v2</i> (see above).

<i>virtual void</i>	<i>obs.before_modify_vertex(Vertex_handle v, Point_2 p)</i>	issued just before a vertex <i>v</i> is modified to be associated with the point <i>p</i> .
<i>virtual void</i>	<i>obs.after_modify_vertex(Vertex_handle v)</i>	issued immediately after an existing vertex <i>v</i> has been modified.
<i>virtual void</i>	<i>obs.before_modify_edge(Halfedge_handle e, X_monotone_curve_2 c)</i>	issued just before an edge <i>e</i> is modified to be associated with the <i>x</i> -monotone curve <i>c</i> .
<i>virtual void</i>	<i>obs.after_modify_edge(Halfedge_handle e)</i>	issued immediately after an existing edge <i>e</i> has been modified.
<i>virtual void</i>	<i>obs.before_split_edge(Halfedge_handle e, Vertex_handle v, X_monotone_curve_2 c1, X_monotone_curve_2 c2)</i>	issued just before an edge <i>e</i> is split into two edges that should be associated with the <i>x</i> -monotone curves <i>c1</i> and <i>c2</i> . The vertex <i>v</i> corresponds to the split point, and will be used to separate the two resulting edges.
<i>virtual void</i>	<i>obs.after_split_edge(Halfedge_handle e1, Halfedge_handle e2)</i>	issued immediately after an existing edge has been split into the two given edges <i>e1</i> and <i>e2</i> .
<i>virtual void</i>	<i>obs.before_split_fictitious_edge(Halfedge_handle e, Vertex_handle v)</i>	issued just before a fictitious edge <i>e</i> is split into two. The vertex at infinity <i>v</i> corresponds to the split point, and will be used to separate the two resulting edges.
<i>virtual void</i>	<i>obs.after_split_fictitious_edge(Halfedge_handle e1, Halfedge_handle e2)</i>	issued immediately after an existing fictitious edge has been split into the two given fictitious edges <i>e1</i> and <i>e2</i> .
<i>virtual void</i>	<i>obs.before_split_face(Face_handle f, Halfedge_handle e)</i>	issued just before a face <i>f</i> is split into two, as a result of the insertion of the edge <i>e</i> into the arrangement.
<i>virtual void</i>	<i>obs.after_split_face(Face_handle f1, Face_handle f2, bool is_hole)</i>	issued immediately after the existing face <i>f1</i> has been split, such that a portion of it now forms a new face <i>f2</i> . The flag <i>is_hole</i> designates whether <i>f2</i> forms a hole inside <i>f1</i> .

<i>virtual void</i>	<i>obs.before_split_outer_ccb(Face_handle f, Ccb_halfedge_circulator h, Halfedge_handle e)</i>	issued just before outer ccb <i>h</i> inside a face <i>f</i> is split into two, as a result of the removal of the edge <i>e</i> from the arrangement.
<i>virtual void</i>	<i>obs.after_split_outer_ccb(Face_handle f, Ccb_halfedge_circulator h1, Ccb_halfedge_circulator h2)</i>	issued immediately after outer ccb the face <i>f</i> has been split, resulting in the two holes <i>h1</i> and <i>h2</i> .
<i>virtual void</i>	<i>obs.before_split_inner_ccb(Face_handle f, Ccb_halfedge_circulator h, Halfedge_handle e)</i>	issued just before inner ccb <i>h</i> inside a face <i>f</i> is split into two, as a result of the removal of the edge <i>e</i> from the arrangement.
<i>virtual void</i>	<i>obs.after_split_inner_ccb(Face_handle f, Ccb_halfedge_circulator h1, Ccb_halfedge_circulator h2)</i>	issued immediately after inner ccb the face <i>f</i> has been split, resulting in the two holes <i>h1</i> and <i>h2</i> .
<i>virtual void</i>	<i>obs.before_add_outer_ccb(Face_handle f, Halfedge_handle e)</i>	issued just before the edge <i>e</i> is inserted as a new outer ccb inside the face <i>f</i> .
<i>virtual void</i>	<i>obs.after_add_outer_ccb(Ccb_halfedge_circulator h)</i>	issued immediately after a new outer ccb <i>h</i> has been cre- ated. The outer ccb always consists of a single pair of twin halfedges.
<i>virtual void</i>	<i>obs.before_add_inner_ccb(Face_handle f, Halfedge_handle e)</i>	issued just before the edge <i>e</i> is inserted as a new inner ccb inside the face <i>f</i> .
<i>virtual void</i>	<i>obs.after_add_inner_ccb(Ccb_halfedge_circulator h)</i>	issued immediately after a new inner ccb <i>h</i> has been cre- ated. The inner ccb always consists of a single pair of twin halfedges.
<i>virtual void</i>	<i>obs.before_add_isolated_vertex(Face_handle f, Vertex_handle v)</i>	issued just before the vertex <i>v</i> is inserted as an isolated vertex inside the face <i>f</i> .

<i>virtual void</i>	<i>obs.after_add_isolated_vertex(Vertex_handle v)</i>	issued immediately after the vertex <i>v</i> has been set as an isolated vertex.
<i>virtual void</i>	<i>obs.before_merge_edge(Halfedge_handle e1, Halfedge_handle e2, X_monotone_curve_2 c)</i>	issued just before the two edges <i>e1</i> and <i>e2</i> are merged to form a single edge that will be associated with the <i>x</i> -monotone curve <i>c</i> .
<i>virtual void</i>	<i>obs.after_merge_edge(Halfedge_handle e)</i>	issued immediately after two edges have been merged to form the edge <i>e</i> .
<i>virtual void</i>	<i>obs.before_merge_fictitious_edge(Halfedge_handle e1, Halfedge_handle e2)</i>	issued just before the two fictitious edges <i>e1</i> and <i>e2</i> are merged to form a single fictitious edge.
<i>virtual void</i>	<i>obs.after_merge_fictitious_edge(Halfedge_handle e)</i>	issued immediately after two fictitious edges have been merged to form the fictitious edge <i>e</i> .
<i>virtual void</i>	<i>obs.before_merge_face(Face_handle f1, Face_handle f2, Halfedge_handle e)</i>	issued just before the two edges <i>f1</i> and <i>f2</i> are merged to form a single face, following the removal of the edge <i>e</i> from the arrangement.
<i>virtual void</i>	<i>obs.after_merge_face(Face_handle f)</i>	issued immediately after two faces have been merged to form the face <i>f</i> .
<i>virtual void</i>	<i>obs.before_merge_outer_ccb(Face_handle f, Ccb_halfedge_circulator h1, Ccb_halfedge_circulator h2, Halfedge_handle e)</i>	issued just before two outer ccbs <i>h1</i> and <i>h2</i> inside the face <i>f</i> are merged to form a single connected component, following the insertion of the edge <i>e</i> into the arrangement.
<i>virtual void</i>	<i>obs.after_merge_outer_ccb(Face_handle f, Ccb_halfedge_circulator h)</i>	issued immediately after two outer ccbs have been merged to form a single outer ccb <i>h</i> inside the face <i>f</i> .

<i>virtual void</i>	<i>obs.before_merge_inner_ccb(Face_handle f,</i> <i> Ccb_halfedge_circulator h1,</i> <i> Ccb_halfedge_circulator h2,</i> <i> Halfedge_handle e)</i>	<p>issued just before two inner ccbs <i>h1</i> and <i>h2</i> inside the face <i>f</i> are merged to form a single connected component, following the insertion of the edge <i>e</i> into the arrangement.</p>
<i>virtual void</i>	<i>obs.after_merge_inner_ccb(Face_handle f, Ccb_halfedge_circulator h)</i>	<p>issued immediately after two inner ccbs have been merged to form a single inner ccb <i>h</i> inside the face <i>f</i>.</p>
<i>virtual void</i>	<i>obs.before_move_outer_ccb(Face_handle from_f,</i> <i> Face_handle to_f,</i> <i> Ccb_halfedge_circulator h)</i>	<p>issued just before the outer ccb <i>h</i> is moved from one face to another. This can happen if the face <i>to_f</i> containing the outer ccb has just been split from <i>from_f</i>.</p>
<i>virtual void</i>	<i>obs.after_move_outer_ccb(Ccb_halfedge_circulator h)</i>	<p>issued immediately after the outer ccb <i>h</i> has been moved to a new face.</p>
<i>virtual void</i>	<i>obs.before_move_inner_ccb(Face_handle from_f,</i> <i> Face_handle to_f,</i> <i> Ccb_halfedge_circulator h)</i>	<p>issued just before the inner ccb <i>h</i> is moved from one face to another. This can happen if the face <i>to_f</i> containing the inner ccb has just been split from <i>from_f</i>.</p>
<i>virtual void</i>	<i>obs.after_move_inner_ccb(Ccb_halfedge_circulator h)</i>	<p>issued immediately after the inner ccb <i>h</i> has been moved to a new face.</p>
<i>virtual void</i>	<i>obs.before_move_isolated_vertex(Face_handle from_f,</i> <i> Face_handle to_f,</i> <i> Vertex_handle v)</i>	<p>issued just before the isolated vertex <i>v</i> is moved from one face to another. This can happen if the face <i>to_f</i> containing the isolated vertex has just been split from <i>from_f</i>.</p>
<i>virtual void</i>	<i>obs.after_move_isolated_vertex(Vertex_handle v)</i>	<p>issued immediately after the isolated vertex <i>v</i> has been moved to a new face.</p>
<i>virtual void</i>	<i>obs.before_remove_vertex(Vertex_handle v)</i>	<p>issued just before the vertex <i>v</i> is removed from the arrangement.</p>

<i>virtual void</i>	<i>obs.after_remove_vertex()</i>	issued immediately after a vertex has been removed (and deleted) from the arrangement.
<i>virtual void</i>	<i>obs.before_remove_edge(Halfedge_handle e)</i>	issued just before the edge <i>e</i> is removed from the arrangement.
<i>virtual void</i>	<i>obs.after_remove_edge()</i>	issued immediately after an edge has been removed (and deleted) from the arrangement.
<i>virtual void</i>	<i>obs.before_remove_outer_ccb(Face_handle f, Ccb_halfedge_circulator h)</i>	issued just before the outer ccb <i>f</i> is removed from inside the face <i>f</i> .
<i>virtual void</i>	<i>obs.after_remove_outer_ccb(Face_handle f)</i>	issued immediately after a outer ccb has been removed (and deleted) from inside the face <i>f</i> .
<i>virtual void</i>	<i>obs.before_remove_inner_ccb(Face_handle f, Ccb_halfedge_circulator h)</i>	issued just before the inner ccb <i>f</i> is removed from inside the face <i>f</i> .

CGAL::Arrangement_with_history_2<Traits,Dcel>

Definition

An object *arr* of the class *Arrangement_with_history_2<Traits,Dcel>* represents the planar subdivision induced by a set of input curves *C*. The arrangement is represented as a doubly-connected edge-list (DCEL). As is the case for the *Arrangement_2<Traits,Dcel>*, each DCEL vertex is associated with a point and each edge is associated with an *x*-monotone curve whose interior is disjoint from all other edges and vertices. Each such *x*-monotone curve is a subcurve of some $C \in C$ — or may represent an overlap among several curves in *C*.

The *Arrangement_with_history_2<Traits,Dcel>* class-template extends the *Arrangement_2* class-template by keeping an additional container of input curves representing *C*, and by maintaining a cross-mapping between these curves and the arrangement edges they induce. This way it is possible to determine the inducing curve(s) of each arrangement edge. This mapping also allows the traversal of input curves, and the traversal of edges induced by each curve.

The *Arrangement_with_history_2<Traits,Dcel>* template has two parameters:

- The *Traits* template-parameter should be instantiated with a model of the *ArrangementTraits_2* concept. The traits class defines the *Curve_2* type, which represents an input curve. It also defines the types of *x*-monotone curves and two-dimensional points, namely *X_monotone_curve_2* and *Point_2*, respectively, and supports basic geometric predicates on them.
- The *Dcel* template-parameter should be instantiated with a class that is a model of the *ArrangementDcelWithRebind* concept. The value of this parameter is by default *Arr_default_dcel<Traits>*.

Inherits From

Arrangement_2<Traits,Dcel>

`#include <CGAL/Arrangement_with_history_2.h>`

Types

`typedef Arrangement_with_history_2<Traits_2,Dcel>`

Self; a private type used as an abbreviation of the *Arrangement_with_history_2<Traits,Dcel>* type hereafter.

`Arrangement_with_history_2<Traits,Dcel>:: Traits_2`

the traits class in use.

`Arrangement_with_history_2<Traits,Dcel>:: Dcel`

the DCEL representation of the arrangement.

`typedef typename Traits_2::Point_2`

Point_2; the point type, as defined by the traits class.

typedef typename Traits_2::X_monotone_curve_2

X_monotone_curve_2;

the *x*-monotone curve type, as defined by the traits class.

typedef typename Traits_2::Curve_2

Curve_2;

the curve type, as defined by the traits class.

In addition, the nested types *Vertex*, *Halfedge* and *Face* are defined, as well as all handle, iterator and circulator types, as defined by the *Arrangement_2* class-template (page [2046](#)).

Arrangement_with_history_2<Traits,Dcel>:: Curve_handle

a handle for an input curve.

Arrangement_with_history_2<Traits,Dcel>:: Curve_iterator

a bidirectional iterator over the curves that induce the arrangement. Its value-type is *Curve_2*.

Arrangement_with_history_2<Traits,Dcel>:: Induced_edge_iterator

an iterator over the edges induced by an input curve. Its value type is *Halfedge_handle*.

Arrangement_with_history_2<Traits,Dcel>:: Originating_curve_iterator

an iterator for the curves that originate a given arrangement edge. Its value type is *Curve_handle*.

Creation

Arrangement_with_history_2<Traits,Dcel> arr;

constructs an empty arrangement containing one unbounded face, which corresponds to the whole plane.

Arrangement_with_history_2<Traits,Dcel> arr(Self other);

copy constructor.

*Arrangement_with_history_2<Traits,Dcel> arr(Traits_2 *traits);*

constructs an empty arrangement that uses the given *traits* instance for performing the geometric predicates.

Assignment Methods

<i>Self</i> &	<i>arr = other</i>	assignment operator.
<i>void</i>	<i>arr.assign(Self other)</i>	assigns the contents of another arrangement.
<i>void</i>	<i>arr.clear()</i>	clears the arrangement.

Access Functions

See the *Arrangement_2* reference pages (page [2046](#)) for the full list.

• Accessing the Input Curves:

<i>Size</i>	<i>arr.number_of_curves()</i>	returns the number of input curves that induce the arrangement.
<i>Curve_iterator</i>	<i>arr.curves_begin()</i>	returns the begin-iterator of the curves inducing the arrangement.
<i>Curve_iterator</i>	<i>arr.curves_end()</i>	returns the past-the-end iterator of the curves inducing the arrangement.
<i>Size</i>	<i>arr.number_of_induced_edges(Curve_handle ch)</i>	returns the number of arrangement edges induced by the curve <i>ch</i> .
<i>Induced_edge_iterator</i>	<i>arr.induced_edges_begin(Curve_handle ch)</i>	returns the begin-iterator of the edges induced by the curve <i>ch</i> .
<i>Induced_edge_iterator</i>	<i>arr.induced_edges_end(Curve_handle ch)</i>	returns the past-the-end iterator of the edges induced by the curve <i>ch</i> .
<i>Size</i>	<i>arr.number_of_originating_curves(Halfedge_handle e)</i>	returns the number of input curves that originate the edge <i>e</i> .

Originating_curve_iterator

arr.originating_curves_begin(Halfedge_handle e)

returns the begin-iterator of the curves originating the edge *e*.

Originating_curve_iterator

arr.originating_curves_end(Halfedge_handle e)

returns the past-the-end iterator of the curves originating the edge *e*.

Modifiers

See the *Arrangement_2* reference pages (page [2046](#)) for the full list of functions for modifying arrangement vertices.

• Modifying Arrangement Edges:

The following functions override their counterparts in the *Arrangement_2* class, as they also maintain the cross-relationships between the input curves and the edges they induce.

Halfedge_handle *arr.split_edge(Halfedge_handle e, Point_2 p)*

splits the edge *e* into two edges (more precisely, into two halfedge pairs), at a given split point *p*. The function returns a handle for the halfedge whose source is the same as *e->source()* and whose target vertex is the split point.

Precondition: *p* lies in the interior of the curve associated with *e*.

Halfedge_handle *arr.merge_edge(Halfedge_handle e1, Halfedge_handle e2)*

merges the edges represented by *e1* and *e2* into a single edge. The function returns a handle for one of the merged halfedges.

Precondition: *e1* and *e2* share a common end-vertex, of degree 2, and the *x*-monotone curves associated with *e1* and *e2* are mergeable into a single *x*-monotone curves.

Face_handle *arr.remove_edge(Halfedge_handle e,*
 bool remove_source = true,
 bool remove_target = true)

removes the edge *e* from the arrangement. Since the *e* may be the only edge incident to its source vertex (or its target vertex), this vertex can be removed as well. The flags *remove_source* and *remove_target* indicate whether the endpoints of *e* should be removed, or whether they should be left as isolated vertices in the arrangement. If the operation causes two faces to merge, the merged face is returned. Otherwise, the face to which the edge was incident is returned.

CGAL::Arr_parameter_space

```
#include <CGAL/Arr_enums.h>
```

```
enum Arr_parameter_space { ARR_LEFT_BOUNDARY,  
                           ARR_RIGHT_BOUNDARY,  
                           ARR_BOTTOM_BOUNDARY,  
                           ARR_TOP_BOUNDARY,  
                           ARR_INTERIOR}
```

CGAL::remove_curve

Definition

The function *remove_curve* removes a given curve from a given arrangement.

```
#include <CGAL/Arrangement_with_history_2.h>
```

```
template <class Traits, class Dcel>  
Size      remove_curve( Arrangement_with_history_2<Traits,Dcel>& arr,  
                        typename Arrangement_with_history_2<Traits,Dcel>::Curve_handle ch)
```

remove_curve removes a curve, specified by its handle *ch*, from the arrangement *arr*, by deleting all the edges it induces. The function returns the number of deleted edges.

ArrangementWithHistoryInputFormatter

A model for the ArrangementWithHistoryInputFormatter concept supports a set of functions that enable reading an arrangement-with-history instance from an input stream using a specific format.

Refines

ArrangementInputFormatter

Types

ArrangementWithHistoryInputFormatter:: Arr_with_history_2

the type of arrangement to input.

typedef typename Arrangement_2::Curve_2

Curve_2; the inducing curve type.

Formatted Input Functions

void inf.read_curves_begin()

reads a message indicating the beginning of the inducing curves.

void inf.read_curves_end()

reads a message indicating the end of the inducing curves.

void inf.read_curve_begin()

reads a message indicating the beginning of a single curve record.

void inf.read_curve_end()

reads a message indicating the end of a single curve record.

void inf.read_curve(Curve_2& c)

reads a curve.

void inf.read_induced_edges_begin()

reads a message indicating the beginning of the set of edges induced by the current curve.

void inf.read_induced_edges_end()

reads a message indicating the end of the induced edges set.

Has Models

Arr_with_history_text_formatter<*ArrFormatter*> (page [2228](#))

ArrangementWithHistoryOutputFormatter

A model for the ArrangementWithHistoryOutputFormatter concept supports a set of functions that enable writing an arrangement-with-history instance to an output stream using a specific format.

Refines

ArrangementOutputFormatter

Types

ArrangementWithHistoryOutputFormatter:: Arr_with_history_2

the type of arrangement to output.

typedef typename Arrangement_2::Curve_2

Curve_2; the inducing curve type.

Formatted Output Functions

void outf.write_curves_begin()

writes a message indicating the beginning of the inducing curves.

void outf.write_curves_end()

writes a message indicating the end of the inducing curves.

void outf.write_curve_begin()

writes a message indicating the beginning of a single curve record.

void outf.write_curve_end()

writes a message indicating the end of a single curve record.

void outf.write_curve(Curve_2 c)

writes a curve.

void outf.write_induced_edges_begin()

writes a message indicating the beginning of the set of edges induced by the current curve.

void *outf.write_induced_edges_end()*

writes a message indicating the end of the induced edges set.

Has Models

Arr_with_history_text_formatter<*ArrFormatter*> (page [2228](#))

CGAL::Arr_with_history_text_formatter<ArrFormatter>

Definition

Arr_with_history_text_formatter<*ArrFormatter*> defines the format of an arrangement in an input or output stream (typically a file stream), thus enabling reading and writing an arrangement-with-history instance using a simple text format.

The *ArrFormatter* parameter serves as a base class for *Arr_with_history_text_formatter*<*ArrFormatter*> and must be a model of the *ArrangementInputFormatter* and the *ArrangementOutputFormatter* concepts. It is used to read or write the base arrangement, while the derived class is responsible for reading and writing the set of curves inducing the arrangement and maintaining the relations between these curves and the edges they induce.

31.1 Introduction

Let $\mathcal{C} = \{C_1, C_2, \dots, C_n\}$ be a set of curves. We wish to compute all intersection points between two curves in the set in an output-sensitive manner, without having to go over all $O(n^2)$ curve pairs. To this end, we sweep an imaginary line l from $x = -\infty$ to $x = \infty$ over the plane. While sweeping the plane, we keep track of the order of curves intersecting it. This order changes at a finite number of *event points*, such that we only have to calculate the intersection points between two curves when they become contiguous. For more details on the *sweep-line algorithm* see, for example, [dBvKOS00, Chapter 2].

This chapter describes three functions implemented using the sweep-line algorithm: given a collection of input curves, compute all intersection points, compute the set of subcurves that are pairwise interior-disjoint induced by them, and checking whether there is at least one pair of curves among them that intersect in their interior.

The implementation is robust. It supports general curves and handles all degenerate cases, including overlapping curves, vertical segments, and tangency between curves. The robustness of the algorithm is guaranteed if the functions are instantiated with a traits class that employs certified computations. This traits class must be a model of the *ArrangementTraits_2* concept — see the Chapter 30 for more details.

The complexity of the sweep-line algorithm is $O((n+k)\log n)$ where n is the number of the input curves and k is the number of intersection points induced by these curves.

31.2 Example

The simple program listed below computes intersection points induced by a set of four input segments illustrated in figure 31.1.

```
#include <CGAL/Cartesian.h>
#include <CGAL/MP_Float.h>
#include <CGAL/Quotient.h>
#include <CGAL/Arr_segment_traits_2.h>
#include <CGAL/Sweep_line_2_algorithms.h>
#include <list>

typedef CGAL::Quotient<CGAL::MP_Float>      NT;
typedef CGAL::Cartesian<NT>                Kernel;
typedef Kernel::Point_2                     Point_2;
typedef CGAL::Arr_segment_traits_2<Kernel>  Traits_2;
typedef Traits_2::Curve_2                   Segment_2;

int main()
{
    // Construct the input segments.
    Segment_2 segments[] = {Segment_2 (Point_2 (1, 5), Point_2 (8, 5)),
                             Segment_2 (Point_2 (1, 1), Point_2 (8, 8)),
                             Segment_2 (Point_2 (3, 1), Point_2 (3, 8)),
                             Segment_2 (Point_2 (8, 5), Point_2 (8, 8))};

    // Compute all intersection points.
    std::list<Point_2>      pts;

    CGAL::compute_intersection_points (segments, segments + 4,
                                       std::back_inserter (pts));

    // Print the result.
    std::cout << "Found " << pts.size() << " intersection points: " <<
        std::endl;
    std::copy (pts.begin(), pts.end(),
               std::ostream_iterator<Point_2>(std::cout, "\n"));

    // Compute the non-intersecting sub-segments induced by the input
    // segments.
    std::list<Segment_2>    sub_segs;

    CGAL::compute_subcurves(segments, segments + 4,
                           std::back_inserter(sub_segs));

    std::cout << "Found " << sub_segs.size()
               << " interior-disjoint sub-segments." << std::endl;

    CGAL_assertion (CGAL::do_curves_intersect (segments, segments + 4));

    return 0;
}
```

31.3 Design and Implementation History

The current version of the sweep-line algorithm was written by Baruch Zukerman, based on previous implementations by Ester Ezra and Tali Zvi.

2D Intersection of Curves

Reference Manual

Baruch Zukerman and Ron Wein

This chapter describes three functions implemented using the sweep-line algorithm: given a collection \mathcal{C} of planar curves, compute all intersection points among them, obtain the set of maximal pairwise interior-disjoint subcurves of the curves in \mathcal{C} , or check whether there is at least one pair of curves in \mathcal{C} that intersect in their interior.

The first two operations are performed in an output-sensitive manner.

CGAL::compute_intersection_points

```
#include <CGAL/Sweep_line_2_algorithms.h>

template <class InputIterator, class OutputIterator, class Traits>
OutputIterator compute_intersection_points( InputIterator curves_begin,
                                           InputIterator curves_end,
                                           OutputIterator points,
                                           bool report_endpoints = false,
                                           Traits traits = Default_traits())
```

given a range of curves, compute all intersection points between two (or more) input curves. If the flag *report_endpoints* is *true*, then the curve endpoints are reported as well. The *Traits* type must be a model of the *ArrangementTraits_2* concept, such that the value-type of *InputIterator* is *Traits::Curve_2*, and the value-type of *OutputIterator* is *Traits::Point_2*. The output points are reported in an increasing *xy*-lexicographical order.

CGAL::compute_subcurves

```
#include <CGAL/Sweep_line_2_algorithms.h>

template <class InputIterator, class OutputIterator, class Traits>
OutputIterator compute_subcurves( InputIterator curves_begin,
                                InputIterator curves_end,
                                OutputIterator subcurves,
                                bool multiple_overlaps = false,
                                Traits traits = Default_traits())
```

given a range of curves, compute all x -monotone subcurves that are pairwise disjoint in their interior, as induced by the input curves. If the flag *multiple_overlaps* is *true*, then a subcurve that represents an overlap of k input curves is reported k times; otherwise, each subcurve is reported only once. The *Traits* type must be a model of the *ArrangementTraits_2* concept, such that the value-type of *InputIterator* is *Traits::Curve_2*, and the value-type of *OutputIterator* is *Traits::X_monotone_curve_2*.

CGAL::do_curves_intersect

```
#include <CGAL/Sweep_line_2_algorithms.h>
```

```
template <class InputIterator, class Traits>
```

```
bool do_curves_intersect( InputIterator curves_begin,  
                          InputIterator curves_end,  
                          Traits traits = Default_traits())
```

given a range of curves, check whether there is at least one pair of curves that intersect in their interior. The function returns *true* if such a pair is found, and *false* if all curves are pairwise disjoint in their interior. The *Traits* type must be a model of the *ArrangementTraits_2* concept, such that the value-type of *InputIterator* is *Traits::Curve_2*.

32.1 Introduction

Snap Rounding (SR, for short) is a well known method for converting arbitrary-precision arrangements of segments into a fixed-precision representation [GGHT97, GM98, Hob99]. In the study of robust geometric computing, it can be classified as a finite precision approximation technique. Iterated Snap Rounding (ISR, for short) is a modification of SR in which each vertex is at least half-the-width-of-a-pixel away from any non-incident edge [HP02]. This package supports both methods. Algorithmic details and experimental results are given in [HP02].

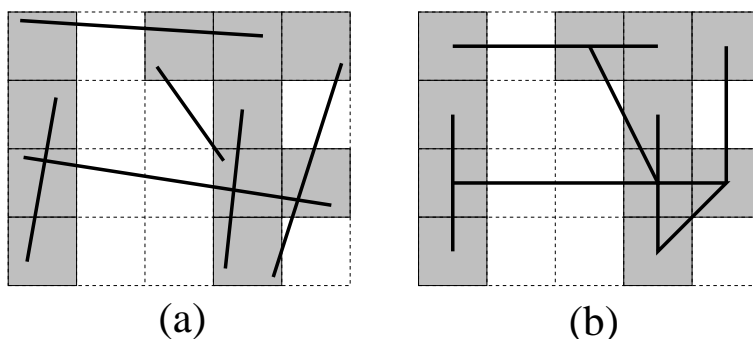

Figure 32.1: An arrangement of segments before (a) and after (b) SR (hot pixels are shaded)

32.2 What is Snap Rounding/Iterated Snap Rounding

Given a finite collection S of segments in the plane, the arrangement of S denoted $\mathcal{A}(S)$ is the subdivision of the plane into vertices, edges, and faces induced by S . A *vertex* of the arrangement is either a segment endpoint or the intersection of two segments. Given an arrangement of segments whose vertices are represented with arbitrary-precision coordinates, the SR procedure `snap_rounding_2<Traits,InputIterator,OutputContainer>` proceeds as follows. We tile the plane with a grid of unit squares, *pixels*, each centered at a point with integer coordinates. A pixel is *hot* if it contains a vertex of the arrangement. Each vertex of the arrangement is replaced by the center of the hot pixel containing it and each edge e is replaced by the polygonal chain through the centers of the hot pixels met by e , in the same order as they are met by e . Figure 32.1 demonstrates the results of SR.

In a snap-rounded arrangement, the distance between a vertex and a non-incident edge can be extremely small compared with the width of a pixel in the grid used for rounding. ISR is a modification of SR which makes a vertex and a non-incident edge well separated (the distance between each is at least half-the-width-of-a-pixel). However, the guaranteed quality of the approximation in ISR degrades. Figure 32.2 depicts the results of SR and ISR on the same input. Conceptually, the ISR procedure is equivalent to repeated application of SR, namely we apply SR to the original set of segments, then we use the output of SR as input to another round of SR and so on until all the vertices are well separated from non-incident edges. Algorithmically we operate differently, as this repeated application of SR would have resulted in an efficient overall process. The algorithmic details are given in [HP02].

32.3 Terms and Software Design

Our package supports both schemes, implementing the algorithm described in [HP02]. Although the paper only describes an algorithm for ISR, it is easy to derive an algorithm for SR, by performing only the first rounding level for each segment.

The input to the program is a set S of n segments, $S = \{s_1, \dots, s_n\}$ and the output is a set G of n polylines, with a polyline g_i for each input segments s_i . An input segment is given by the coordinates of its endpoints. An output polyline is given by the ordered set of vertices v_0, \dots, v_k along the polyline. The polyline consists of the segments $(v_0v_1), \dots, (v_{k-1}v_k)$.

There are three template parameters: *Traits* is the underlying geometry, i.e., the number type used and the coordinate representation. *InputIterator* is the type of the iterators that point to the first and after-the-last elements of the input. Finally, *OutputContainer* is the type of the output container.

Since the algorithm requires kernel functionalities such as the rounding to the center of a pixel, a special traits class must be provided. The precise description of the requirements is given by the concept *SnapRoundingTraits_2*. The class `Snap_rounding_traits_2` is a model of this concept.

32.4 Four Line Segment Example

The following example generates an ISR representation of an arrangement of four line segments. In particular it produces a list of points that are the vertices of the resulting polylines in a plane tiled with one-unit square pixels.

```
#include <CGAL/basic.h>
#include <CGAL/Cartesian.h>
```

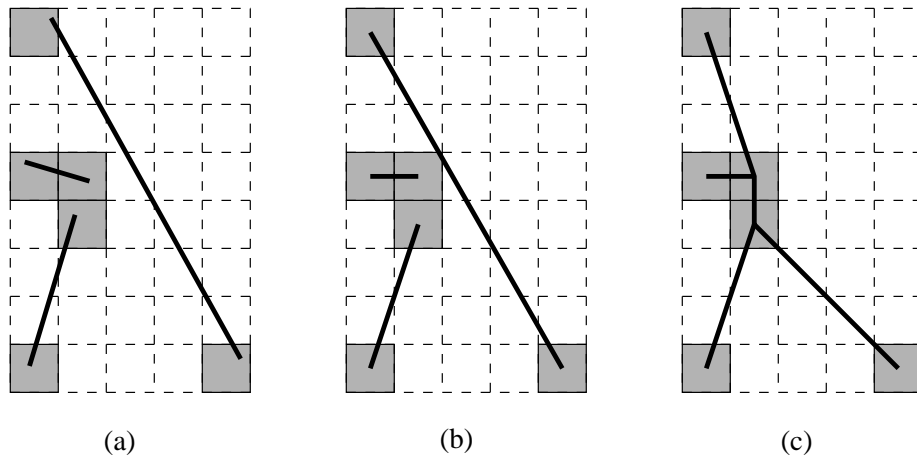

Figure 32.2: An arrangement of segments before (a), after SR (b) and ISR (c) (hot pixels are shaded).

```
#include <CGAL/Quotient.h>
#include <CGAL/MP_Float.h>
#include <CGAL/Snap_rounding_traits_2.h>
#include <CGAL/Snap_rounding_2.h>

typedef CGAL::Quotient<CGAL::MP_Float>      Number_type;
typedef CGAL::Cartesian<Number_type>       Kernel;
typedef CGAL::Snap_rounding_traits_2<Kernel> Traits;
typedef Kernel::Segment_2                  Segment_2;
typedef Kernel::Point_2                    Point_2;
typedef std::list<Segment_2>               Segment_list_2;
typedef std::list<Point_2>                 Polyline_2;
typedef std::list<Polyline_2>              Polyline_list_2;

int main()
{
    Segment_list_2 seg_list;
    Polyline_list_2 output_list;

    seg_list.push_back(Segment_2(Point_2(0, 0), Point_2(10, 10)));
    seg_list.push_back(Segment_2(Point_2(0, 10), Point_2(10, 0)));
    seg_list.push_back(Segment_2(Point_2(3, 0), Point_2(3, 10)));
    seg_list.push_back(Segment_2(Point_2(7, 0), Point_2(7, 10)));

    // Generate an iterated snap-rounding representation, where the centers
    // of
    // the hot pixels bear their original coordinates, using 5 kd trees:

    CGAL::snap_rounding_2<Traits, Segment_list_2::const_iterator, Polyline_list_2>
        (seg_list.begin(), seg_list.end(), output_list, 1.0, true, false, 5);

    int counter = 0;
    Polyline_list_2::const_iterator iter1;
    for (iter1 = output_list.begin(); iter1 != output_list.end(); ++iter1)
    {
        std::cout << "Polyline number " << ++counter << ":\n";
    }
}
```

```

Polyline_2::const_iterator iter2;
for (iter2 = iter1->begin(); iter2 != iter1->end(); ++iter2)
    std::cout << "      (" << iter2->x() << ":" << iter2->y() << ")\n";
}

return(0);
}

```

File: examples/Snap_rounding_2/snap_rounding.cpp

This program generates four polylines, one for each input segment. The exact output follows:

Polyline number 1:

```

(0/4:0/4)
(12/4:12/4)
(20/4:20/4)
(28/4:28/4)
(40/4:40/4)

```

Polyline number 2:

```

(0/4:40/4)
(12/4:28/4)
(20/4:20/4)
(28/4:12/4)
(40/4:0/4)

```

Polyline number 3:

```

(12/4:0/4)
(12/4:12/4)
(12/4:28/4)
(12/4:40/4)

```

Polyline number 4:

```

(28/4:0/4)
(28/4:12/4)
(28/4:28/4)
(28/4:40/4)

```

The package is supplied with a graphical demo program that opens a window, allows the user to edit segments dynamically, applies a selected snap-rounding procedures, and displays the result onto the same window (see `<CGAL_ROOT>/demo/Snap_rounding_2/demo.cpp`).

CGAL::snap_rounding_2

Definition

Snap Rounding (SR, for short) is a well known method for converting arbitrary-precision arrangements of segments into a fixed-precision representation [GGHT97, GM98, Hob99]. In the study of robust geometric computing, it can be classified as a finite precision approximation technique. Iterated Snap Rounding (ISR, for short) is a modification of SR in which each vertex is at least half-the-width-of-a-pixel away from any non-incident edge [HP02]. This package supports both methods. Algorithmic details and experimental results are given in [HP02].

Given a finite collection \mathcal{S} of segments in the plane, the arrangement of \mathcal{S} denoted $\mathcal{A}(\mathcal{S})$ is the subdivision of the plane into vertices, edges, and faces induced by \mathcal{S} . A *vertex* of the arrangement is either a segment endpoint or the intersection of two segments. Given an arrangement of segments whose vertices are represented with arbitrary-precision coordinates, SR proceeds as follows. We tile the plane with a grid of unit squares, *pixels*, each centered at a point with integer coordinates. A pixel is *hot* if it contains a vertex of the arrangement. Each vertex of the arrangement is replaced by the center of the hot pixel containing it and each edge e is replaced by the polygonal chain through the centers of the hot pixels met by e , in the same order as they are met by e .

In a snap-rounded arrangement, the distance between a vertex and a non-incident edge can be extremely small compared with the width of a pixel in the grid used for rounding. ISR is a modification of SR which makes a vertex and a non-incident edge well separated (the distance between each is at least half-the-width-of-a-pixel). However, the guaranteed quality of the approximation in ISR degrades. For more details on ISR see [HP02].

The traits used here must support (arbitrary-precision) rational number type as this is a basic requirement of SR.

```
#include <CGAL/Snap_rounding_2.h>
```

```
template < class Traits, class InputIterator, class OutputContainer >
void      snap_rounding_2( InputIterator begin,
                           InputIterator end,
                           OutputContainer& output_container,
                           typename Traits::FT pixel_size,
                           bool do_isr = true,
                           bool int_output = true,
                           unsigned int number_of_kd_trees = 1)
```

The first two parameters denote the first and after-the-last iterators of the input segments. The third parameter is a reference to a container of the output polylines. Since a polyline is composed of a sequence of points, a polyline is a container itself. The fifth parameter determines whether to apply ISR or SR.

The forth parameter denotes the pixel size w . The plane will be tiled with square pixels of width w such that the origin is the center of a pixel. The sixth parameter denotes the output representation. If the value of the sixth parameter is *true* then the centers of pixels constitute the integer grid, and hence the vertices of the output polylines will be integers. For example, the coordinates of the center of the pixel to the right of the pixel containing the origin will be $(1,0)$ regardless of the pixel width. If the value of the sixth parameter is *false*, then the centers of hot pixels (and hence the vertices of the output polylines) will bear their original coordinates, which may not necessarily be integers. In the latter case, the coordinates of the center of the pixel to the right of the pixel containing the origin, for example, will be $(w,0)$.

The seventh (and last) parameter is briefly described next; for a detailed description see [HP02].

A basic query used in the algorithm is to report the hot pixels of size w that a certain segment s intersects. An alternative way to do the same is to query the hot pixels' centers contained in a Minkowski sum of s with a pixel of width w centered at the origin; we denote this Minkowski sum by $M(s)$. Since efficiently implementing this kind of query is difficult, we use an orthogonal range-search structure instead. We query with the bounding box $B(M(s))$ of $M(s)$ in a two-dimensional kd-tree which stores the centers of hot pixels. Since $B(M(s))$ in general is larger than $M(s)$, we still need to filter out the hot pixels which do not intersect s .

While this approach is easy to implement with CGAL, it may incur considerable overhead since the area of $B(M(s))$ may be much larger than the area of $M(s)$, possibly resulting in many redundant hot pixels to filter out. Our heuristic solution, which we describe next, is to use a cluster of kd-trees rather than just one. The cluster includes several kd-trees, each has the plane, and hence the centers of hot pixels, rotated by a different angle in the first quadrant of the plane; for our purpose, a rotation by angles outside this quadrant is symmetric to a rotation by an angle in the first quadrant.

Given a parameter c , the angles of rotation are $(i-1)\frac{\pi}{2c}$, $i = 1, \dots, c$, and we construct a kd-tree corresponding to each of these angles. Then for a query segment s , we choose the kd-tree for which the area of $B(M(s))$ is the smallest, in order to (potentially) get less hot pixels to filter out. Since constructing many kd-trees may be costly, our algorithm avoids building a kd-tree which it expects to be queried a relatively small number of times (we estimate this number in advance). How many kd-trees should be used? It is difficult to provide a simple answer for that. There are inputs for which the time to build more than one kd-tree is far greater than the time saved by having to filter out less hot pixels (sparse arrangements demonstrate this behavior), and there are inputs which benefit from using several kd-trees. Thus, the user can control the number of kd-trees with the parameter *number_of_kd_trees*. Typically, but not always, one kd-tree (the default) is sufficient.

Precondition: *pixel_size* must have a positive value and *number_of_kd_trees* must be a positive integer.

SnapRoundingTraits_2

Definition

The concept `SnapRoundingTraits_2` lists the set of requirements that must be fulfilled by an instance of the *Traits* template-parameter of the function `snap_rounding_2<Traits, InputIterator, OutputContainer>()`. This concept provides the types of the geometric primitives used in this class and some function object types for the required predicates on those primitives.

Refines

This concept refines the standard concepts `DefaultConstructible`, `Assignable` and `CopyConstructible`. It also refines the concept `SweepLineTraits_2` (page ??). An instance of this concept is used as the traits class for the `Sweep_line_2.get_intersection_points()` operation. The requirements listed below are induced by components of the `snap_rounding_2()` function other than the call to `Sweep_line_2.get_intersection_points()`. Naturally, some of them may already be listed in `SweepLineTraits_2`.

Types

<code>SnapRoundingTraits_2:: FT</code>	The number type. This type must fulfill the requirements on <i>FieldNumberType</i>
<code>SnapRoundingTraits_2:: Point_2</code>	The point type.
<code>SnapRoundingTraits_2:: Segment_2</code>	The segment type.
<code>SnapRoundingTraits_2:: Iso_rectangle_2</code>	The iso-rectangle type.
<code>SnapRoundingTraits_2:: Construct_vertex_2</code>	Function object. Must provide the operator <i>Point_2 operator()(Segment_2 seg, int i)</i> , which returns the source or target of <i>seg</i> . If <i>i</i> modulo 2 is 0, the source is returned, otherwise the target is returned.
<code>SnapRoundingTraits_2:: Construct_segment_2</code>	Function object. Must provide the operator <i>Segment_2 operator()(Point_2 p, Point_2 q)</i> , which introduces a segment with source <i>p</i> and target <i>q</i> . The segment is directed from the source towards the target.
<code>SnapRoundingTraits_2:: Construct_iso_rectangle_2</code>	Function object. Must provide the operator <i>Iso_rectangle_2 operator()(Point_2 left, Point_2 right, Point_2 bottom, Point_2 top)</i> , which introduces an iso-oriented rectangle for whose minimal <i>x</i> coordinate is the one of <i>left</i> , the maximal <i>x</i> coordinate is the one of <i>right</i> , the minimal <i>y</i> coordinate is the one of <i>bottom</i> , the maximal <i>y</i> coordinate is the one of <i>top</i> .
<code>SnapRoundingTraits_2:: To_double</code>	Function object. Must provide the operator <i>double operator()(FT)</i> , which computes an approximation of a given number of type <i>FT</i> . The precision of this operation is of not high significance, as it is only used in the implementation of the heuristic technique to exploit a cluster of kd-trees rather than just one.

<i>SnapRoundingTraits_2:: Compare_x_2</i>	Function object. Must provide the operator <i>Comparison_result operator()(Point_2 p, Point_2 q)</i> which returns <i>SMALLER</i> , <i>EQUAL</i> or <i>LARGER</i> according to the <i>x</i> -ordering of points <i>p</i> and <i>q</i> .
<i>SnapRoundingTraits_2:: Compare_y_2</i>	Function object. Must provide the operator <i>Comparison_result operator()(Point_2 p, Point_2 q)</i> which returns <i>SMALLER</i> , <i>EQUAL</i> or <i>LARGER</i> according to the <i>y</i> -ordering of points <i>p</i> and <i>q</i> .
<i>SnapRoundingTraits_2:: Snap_2</i>	Rounds a point to a center of a pixel (unit square) in the grid used by the Snap Rounding algorithm. Note that no conversion to an integer grid is done yet. Must have the syntax <i>void operator()(Point_2 p, FT pixel_size, FT &x, FT &y)</i> where <i>p</i> is the input point, <i>pixel_size</i> is the size of the pixel of the grid, and <i>x</i> and <i>y</i> are the <i>x</i> and <i>y</i> -coordinates of the rounded point respectively.
<i>SnapRoundingTraits_2:: Integer_grid_point_2</i>	Convert coordinates into an integer representation where one unit is equal to pixel size. For instance, if a point has the coordinates (3.7, 5.3) and the pixel size is 0.5, then the new point will have the coordinates of (7, 10). Note, however, that the number type remains the same here, although integers are represented. Must have the syntax <i>Point_2 operator()(Point_2 p, NT pixel_size)</i> where <i>p</i> is the converted point and <i>pixel_size</i> is the size of the pixel of the grid.
<i>SnapRoundingTraits_2:: Minkowski_sum_with_pixel_2</i>	Returns the vertices of a polygon, which is the Minkowski sum of a segment and a square centered at the origin with edge size <i>pixel edge</i> . Must have the syntax <i>void operator()(std::list<Point_2>& vertices_list, Segment_2 s, NT unit_square)</i> where <i>vertices_list</i> is the list of the vertices of the Minkowski sum polygon, <i>s</i> is the input segment and <i>unit_square</i> is the edge size of the pixel.

Creation

This concept refines the standard concepts `DefaultConstructible`, `Assignable` and `CopyConstructible`.

Operations

The following functions construct the required function objects occasionally referred as functors listed above.

<i>Construct_vertex_2</i>	<i>traits.construct_vertex_2_object()</i>
<i>Construct_segment_2</i>	<i>traits.construct_segment_2_object()</i>
<i>Construct_iso_rectangle_2</i>	<i>traits.construct_iso_rectangle_2_object()</i>
<i>Compare_x_2</i>	<i>traits.compare_x_2_object()</i>
<i>Compare_y_2</i>	<i>traits.compare_y_2_object()</i>
<i>Snap_2</i>	<i>traits.snap_2_object()</i>
<i>Integer_grid_point_2</i>	<i>traits.integer_grid_point_2_object()</i>
<i>Minkowski_sum_with_pixel_2</i>	<i>traits.minkowski_sum_with_pixel_2_object()</i>

Has Models

CGAL::Snap_rounding_traits<*Kernel*>

See Also

CGAL::Snap_rounding_2<*Traits*>

CGAL::Snap_rounding_traits_2<Kernel>

The class *Snap_rounding_traits_2<Kernel>* is a model of the *SnapRoundingTraits_2* concept, and is the only traits class supplied with the package. This class should be instantiated with an exact geometric kernel that conforms to the CGAL kernel-concept, such as the *Cartesian<gmpq>* kernel.

This geometric kernel must provide an (arbitrary-precision) rational number type (*FT*), *Point_2*, *Segment_2* and *Iso_rectangle_2*. It should be possible to cast numbers of the number type *FT* to double-precision representation. That is, the function *CGAL::to_double(FT)* must be supported.

The *CGAL::to_double()* function is used to implement the operation that rounds the coordinates of a point to a center of a pixel. This operation is one of the traits-concept requirement. The coordinates are converted to double, rounded down to the nearest grid point, and finally adjusted to lie on a center of a pixel. Notice that if *CGAL::to_double()* returns the closet value, then when it rounds up a given coordinate, the resulting ISR, may be imprecise, and the distance between some vertex and a non-incident edge can be slightly less than the guaranteed half-the width-of-a-pixel.

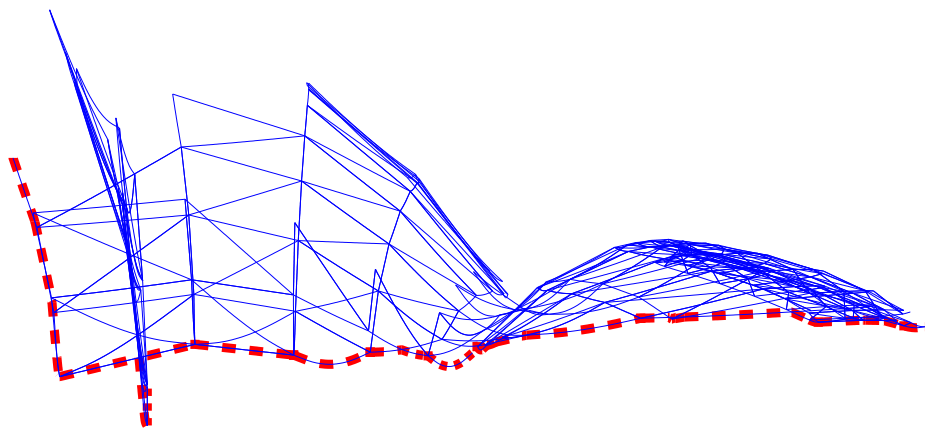

Figure 33.1: The lower envelope of a set of line segments and hyperbolic arc.

33.1 Introduction

A continuous curve C in \mathbb{R}^2 is called *x-monotone*, if every vertical line intersects it at a single point at most. For example, the circle $x^2 + y^2 = 1$ is *not* *xy-monotone* as the vertical line $x = 0$ intersects it at $(0, -1)$ and at $(0, 1)$;

however, it is possible to split the circle into an upper part and a lower part, such that both of these parts are x -monotone. We consider vertical segments as *weakly* x -monotone, to properly handle inputs that contain such vertical curves.

An x -monotone curve can be represented as a univariate function $y = C(x)$, defined over some continuous range $R_C \subseteq \mathbb{R}$. Given a set $C = \{C_1, C_2, \dots, C_n\}$ of x -monotone curves, their *lower envelope* is defined as the point-wise minimum of all curves. Namely, the lower envelope of the set C can be defined as the following function:

$$\mathcal{L}_C(x) = \min_{1 \leq k \leq n} \overline{C}_k(x),$$

where we define $\overline{C}_k(x) = C_k(x)$ for $x \in R_{C_k}$, and $\overline{C}_k(x) = \infty$ otherwise.

Similarly, the *upper envelope* of C is the point-wise maximum of the x -monotone curves in the set:

$$\mathcal{U}_C(x) = \max_{1 \leq k \leq n} \underline{C}_k(x),$$

where in this case $\underline{C}_k(x) = -\infty$ for $x \notin R_{C_k}$.

Given a set of x -monotone curves C , the *minimization diagram* of C is a subdivision of the x -axis into cells, such that the identity of the curves that induce the lower envelope over a specific cell of the subdivision (an edge or a vertex) is the same. In non-degenerate situations, an edge — which represents a continuous interval on the x -axis — is induced by a single curve (or by no curves at all, if there are no x -monotone curves defined over the interval), and a vertex is induced by a single curve and corresponds to one of its endpoints, or by two curves and corresponds to their intersection point. The *maximization diagram* is symmetrically defined for upper envelopes. In the rest of this chapter, we refer to both these diagrams as *envelope diagrams*.

Lower and upper envelopes can be efficiently computed using a divide-and-conquer approach. First, note that the envelope diagram for a single x -monotone curve C_k is trivial to compute: we project the boundary of its range of definition R_{C_k} onto the x -axis and label the features it induces accordingly. Given a set \mathcal{D} of (non necessarily x -monotone) curves in \mathbb{R}^2 , we subdivide each curve into a finite number of weakly x -monotone curves, and obtain the set C . Then, we split the set into two disjoint subsets C_1 and C_2 , and we compute their envelope diagrams recursively. Finally, we merge the diagrams in linear time by traversing both diagrams in parallel.

33.2 The Envelope Diagram

The package basically contains two sets of free functions: *lower_envelope_x_monotone_2* (*begin*, *end*, *diag*) (similarly *upper_envelope_x_monotone_2*()) construct the envelope diagram for a given range of x -monotone curves, while *lower_envelope_2* (*begin*, *end*, *diag*) (similarly *upper_envelope_2*()) construct the envelope diagram for a range of *arbitrary* (not necessarily x -monotone) curves. In this section we explain more on the structure of the envelope diagram these functions output.

A minimization diagram or a maximization diagram is represented by a model of the concept *EnvelopeDiagram_1*. This concept defines the structure of the subdivision of the x -axis into 0-dimensional cells called *vertices*, and 1-dimensional cells called *edges*. The important property of this subdivision is that the identity of the curves that induce the lower envelope (or the upper envelope) over each cell is fixed.

Figure 33.2 shows the lower envelope of a set of eight line segments, and sketches the structure of their minimization diagram. Each diagram vertex v is associated with a point p_v on the envelope, which corresponds to either a curve endpoint or to an intersection point of two (or more) curves. The vertex is therefore associated with a set of x -monotone curves that induce the envelope over p_v . Each vertex is incident to two edges, one lying to its left and the other to its right.

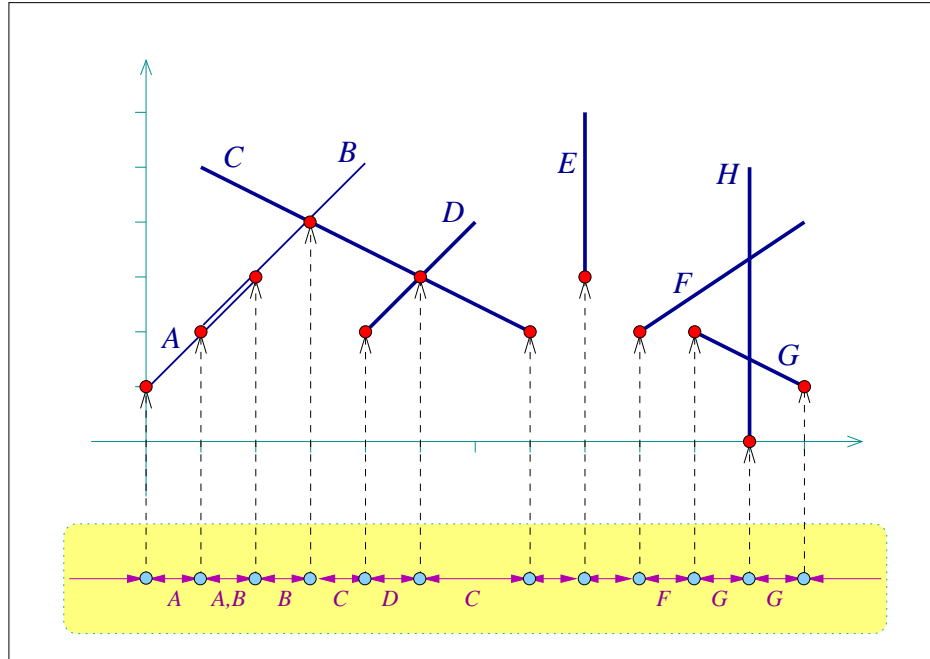

Figure 33.2: The lower envelope of eight line segments, labeled A, \dots, H , as constructed in *envelope_segments.cpp*. The minimization diagram is shown at the bottom, where each diagram vertex points to the point associated with it, and the labels of the segment that induce a diagram edge are displayed below this edge. Note that there exists one edge that represents an overlap (i.e., there are two segments that induce it), and there are also a few edges that represent empty intervals.

An edge in the envelope diagram represents a continuous portion of the x -axis, and is associated with a set of x -monotone curves that induce the envelope over this interval. Note that this set may be empty if no x -monotone curves are defined over this interval. In degenerate situations where curves overlap, there may be more than a single curve that induces the envelope over the interval the edge represents. An envelop diagram of a set of curves either consists of a single unbounded edge (in case the curve set is empty or if the envelope contains a single unbounded curve that is below or above all other curves), or at least one vertex and two unbounded edges, while each additional vertex comes along with an additional edge. It is possible to directly access the *leftmost* edge, representing the unbounded interval that starts at $-\infty$, and the *rightmost* edge, representing the unbounded interval that ends at ∞ . (In the example depicted in Figure 33.2 we have only bounded curves, so the leftmost and rightmost edges represent empty intervals. This is not the case when we deal, for example, with envelopes of sets of lines.)

Any model of the concept must define a geometric traits class, which in turn defines the *Point_2* and *X_monotone_curve_2* types defined with the diagram features. The geometric traits class must be a model of the *ArrangementXMonotoneTraits_2* concept in case we construct envelopes of x -monotone curves. If we are interested in handling arbitrary (not necessarily x -monotone) curves, the traits class must be a model of the *ArrangementTraits_2* concept. This concepts refined the *ArrangementXMonotoneTraits_2* concept; a traits class that models this concepts must also defines a *Curve_2* type, representing an arbitrary planar curve, and provide a functor for subdividing such curves into x -monotone subcurves.

33.3 Examples

33.3.1 Example for Envelope of Line Segments

The following example demonstrates how to compute and traverse the minimization diagram of line segments, as illustrated in Figure 33.2. We use the curve-data traits instantiated by the *Arr_segment_traits_2* class, in order to attach a label (a *char* in this case) to each input segment. We use these labels when we print the minimization diagram:

```
#include <CGAL/Gmpq.h>
#include <CGAL/Cartesian.h>
#include <CGAL/Arr_segment_traits_2.h>
#include <CGAL/Arr_curve_data_traits_2.h>
#include <CGAL/Env_default_diagram_1.h>
#include <CGAL/envelope_2.h>

#include <list>
#include <iostream>

typedef CGAL::Gmpq                               Number_type;
typedef CGAL::Cartesian<Number_type>              Kernel;
typedef CGAL::Arr_segment_traits_2<Kernel>         Segment_traits_2;
typedef Segment_traits_2::X_monotone_curve_2       Segment_2;
typedef CGAL::Arr_curve_data_traits_2<Segment_traits_2,
                                           char>    Traits_2;
typedef Traits_2::Point_2                         Point_2;
typedef Traits_2::X_monotone_curve_2              Labeled_segment_2;
typedef CGAL::Env_default_diagram_1<Traits_2>      Diagram_1;

int main ()
{
    // Construct the input segments and label them 'A' ... 'H'.
    std::list<Labeled_segment_2>    segments;

    segments.push_back (Labeled_segment_2 (Segment_2 (Point_2 (0, 1),
                                                         Point_2 (2, 3)),
                                           'A'));
    segments.push_back (Labeled_segment_2 (Segment_2 (Point_2 (1, 2),
                                                         Point_2 (4, 5)),
                                           'B'));
    segments.push_back (Labeled_segment_2 (Segment_2 (Point_2 (1, 5),
                                                         Point_2 (7, 2)),
                                           'C'));
    segments.push_back (Labeled_segment_2 (Segment_2 (Point_2 (4, 2),
                                                         Point_2 (6, 4)),
                                           'D'));
    segments.push_back (Labeled_segment_2 (Segment_2 (Point_2 (8, 3),
                                                         Point_2 (8, 6)),
                                           'E'));
    segments.push_back (Labeled_segment_2 (Segment_2 (Point_2 (9, 2),
                                                         Point_2 (12, 4)),
```

```

    'F'));
segments.push_back (Labeled_segment_2 (Segment_2 (Point_2 (10, 2),
                                                    Point_2 (12, 1)),
    'G'));
segments.push_back (Labeled_segment_2 (Segment_2 (Point_2 (11, 0),
                                                    Point_2 (11, 5)),
    'H'));

// Compute the minimization diagram that represents their lower
// envelope.
Diagram_1 min_diag;

lower_envelope_x_monotone_2 (segments.begin(), segments.end(),
                             min_diag);

// Print the minimization diagram.
Diagram_1::Edge_const_handle e = min_diag.leftmost();
Diagram_1::Vertex_const_handle v;
Diagram_1::Curve_const_iterator cit;

while (e != min_diag.rightmost())
{
    std::cout << "Edge:";
    if (! e->is_empty())
    {
        for (cit = e->curves_begin(); cit != e->curves_end(); ++cit)
            std::cout << ' ' << cit->data();
    }
    else
        std::cout << " [empty]";
    std::cout << std::endl;

    v = e->right();
    std::cout << "Vertex (" << v->point() << "):";
    for (cit = v->curves_begin(); cit != v->curves_end(); ++cit)
        std::cout << ' ' << cit->data();
    std::cout << std::endl;

    e = v->right();
}
CGAL_assertion (e->is_empty());
std::cout << "Edge: [empty]" << std::endl;

return (0);
}

```

File: examples/Envelope_2/envelope_segments.cpp

33.3.2 Example for Computing the Convex Hull with Envelopes

The next example computes the convex hull of a set of input points by constructing envelopes of unbounded curves, in our case lines that are dual to the input points. Here we use the *Arr_linear_traits_2* class to compute the

lower envelope of the set of dual lines. We read a set of points $\mathcal{P} = p_1, \dots, p_n$ from an input file, and construct the corresponding dual lines $\mathcal{P}^* = p_1^*, \dots, p_n^*$, where the line p^* dual to a point $p = (p_x, p_y)$ is given by $y = p_x x - p_y$. We then compute the convex hull of the point-set \mathcal{P} , using the fact that the lines that form the lower envelope of \mathcal{P}^* are dual to the points along the *upper* part of \mathcal{P} 's convex hull, and the lines that form the upper envelope of \mathcal{P}^* are dual to the points along the *lower* part of the convex hull; see, e.g., [dBvKOS00, Section 11.4] for more details. Note that the leftmost edge of the minimization diagram is associated with the same line as the rightmost edge of the maximization diagram, and vice-versa. We can therefore skip the rightmost edges of both diagrams:

```
#include <CGAL/Gmpq.h>
#include <CGAL/Cartesian.h>
#include <CGAL/Arr_linear_traits_2.h>
#include <CGAL/Arr_curve_data_traits_2.h>
#include <CGAL/Env_default_diagram_1.h>
#include <CGAL/envelope_2.h>
#include <vector>

typedef CGAL::Gmpq                               Number_type;
typedef CGAL::Cartesian<Number_type>             Kernel;
typedef CGAL::Arr_linear_traits_2<Kernel>         Linear_traits_2;
typedef Linear_traits_2::Point_2                  Point_2;
typedef Linear_traits_2::Line_2                   Line_2;
typedef CGAL::Arr_curve_data_traits_2<Linear_traits_2,
                                              unsigned int> Traits_2;
typedef Traits_2::X_monotone_curve_2              Dual_line_2;
typedef CGAL::Env_default_diagram_1<Traits_2>     Diagram_1;

int main (int argc, char **argv)
{
    // Get the name of the input file from the command line, or use the
    // default
    // points.dat file if no command-line parameters are given.
    const char *filename = "ch_points.dat";

    if (argc > 1)
        filename = argv[1];

    // Open the input file.
    std::ifstream in_file (filename);

    if (! in_file.is_open())
    {
        std::cerr << "Failed to open " << filename << " ..." << std::endl;
        return (1);
    }

    // Read the points from the file, and construct their dual lines.
    std::list<Dual_line_2> dual_lines;

    unsigned int n;
    in_file >> n;
    std::vector<Point_2> points;
    points.resize (n);
```

```

unsigned int          k;
for (k = 0; k < n; ++k)
{
    int px, py;
    in_file >> px >> py;
    points[k] = Point_2 (px, py);

    // The line dual to the point (p_x, p_y) is  $y = p_x \cdot x - p_y$ ,
    // or:  $p_x \cdot x - y - p_y = 0$ :
    Line_2 line = Line_2 (Number_type(px), Number_type(-1),
        Number_type(-py));

    // Generate the x-monotone curve based on the line and the point
    // index.
    dual_lines.push_back (Dual_line_2 (line, k));
}
in_file.close();

// Compute the lower envelope of dual lines, which corresponds to the
// upper
// part of the convex hull, and their upper envelope, which corresponds
// to
// the lower part of the convex hull.
Diagram_1          min_diag;
Diagram_1          max_diag;

lower_envelope_x_monotone_2 (dual_lines.begin(), dual_lines.end(),
    min_diag);

upper_envelope_x_monotone_2 (dual_lines.begin(), dual_lines.end(),
    max_diag);

// Output the points along the boundary convex hull in counterclockwise
// order. We start by traversing the minimization diagram from left to
// right, then the maximization diagram from right to left.
Diagram_1::Edge_const_handle e = min_diag.leftmost();

std::cout << "The convex hull of " << points.size() << " input
    points:";
while (e != min_diag.rightmost())
{
    k = e->curve().data();    // The index of the dual point.
    std::cout << " (" << points[k] << ')';
    e = e->right()->right();
}

e = max_diag.rightmost();
while (e != max_diag.leftmost())
{
    k = e->curve().data();    // The index of the dual point.
    std::cout << " (" << points[k] << ')';
    e = e->left()->left();
}
std::cout << std::endl;

```

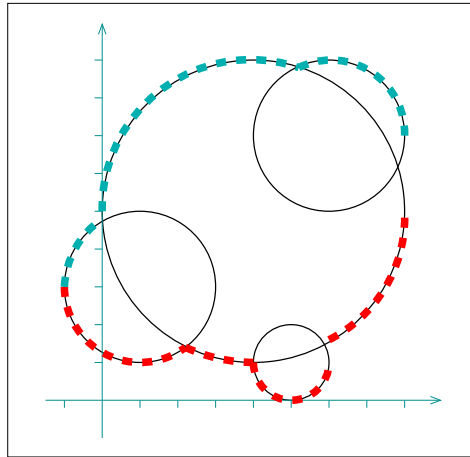

Figure 33.3: A set of four circles, as constructed in *ex_envelope_circles.cpp*. The lower envelope and the upper envelope are shown using thick dashed lines of different colors respectively.

```
    return (0);
}
```

File: examples/Envelope_2/convex_hull.cpp

33.3.3 Example for Envelope of Non-Linear Curves

We conclude by an example of envelopes of non-linear curves. We use the *Arr_circle_segment_traits_2* class to construct the lower and the upper envelopes of a set of four circles, as depicted in Figure 33.3. Note that unlike the two previous examples, here our curves are not *x*-monotone, so we use the functions that compute envelopes of arbitrary curves:

```
#include <CGAL/Gmpq.h>
#include <CGAL/Cartesian.h>
#include <CGAL/Arr_circle_segment_traits_2.h>
#include <CGAL/Arrangement_2.h>
#include <CGAL/Env_default_diagram_1.h>
#include <CGAL/envelope_2.h>

typedef CGAL::Gmpq                               Number_type;
typedef CGAL::Cartesian<Number_type>             Kernel;
typedef Kernel::Point_2                           Kernel_point_2;
typedef Kernel::Circle_2                           Circle_2;
typedef CGAL::Arr_circle_segment_traits_2<Kernel> Traits_2;
typedef Traits_2::Curve_2                         Curve_2;
typedef CGAL::Env_default_diagram_1<Traits_2>     Diagram_1;

/*! Print the given envelope diagram. */
void print_diagram (const Diagram_1& diag)
```

```

{
    Diagram_1::Edge_const_handle    e = diag.leftmost();
    Diagram_1::Vertex_const_handle  v;

    while (e != diag.rightmost())
    {
        std::cout << "Edge: ";
        if (! e->is_empty())
        {
            Circle_2      circ = e->curve().supporting_circle();
            std::cout << " (x - " << CGAL::to_double(circ.center().x()) << ")^2"
            + "
                << " (y - " << CGAL::to_double(circ.center().y()) << ")^2"
            = "
                << CGAL::to_double(circ.squared_radius()) << std::endl;
        }
        else
            std::cout << " [empty]" << std::endl;

        v = e->right();
        std::cout << "Vertex (" << CGAL::to_double(v->point().x()) << ' ' '
            << CGAL::to_double(v->point().y()) << ') ' << std::endl;

        e = v->right();
    }
    CGAL_assertion (e->is_empty());
    std::cout << "Edge: [empty]" << std::endl;

    return;
}

/*! The main program. */
int main ()
{
    // Create four input circles.
    Curve_2      circles[4];

    circles[0] = Circle_2 (Kernel_point_2 (1, 3), CGAL::square(2));
    circles[1] = Circle_2 (Kernel_point_2 (4, 5), CGAL::square(4));
    circles[2] = Circle_2 (Kernel_point_2 (5, 1), CGAL::square(1));
    circles[3] = Circle_2 (Kernel_point_2 (6, 7), CGAL::square(2));

    // Compute the minimization diagram that represents their lower envelope.
    Diagram_1      min_diag;

    lower_envelope_2 (&(circles[0]), &(circles[4]),
                    min_diag);
    print_diagram (min_diag);

    // Compute the maximization diagram that represents the upper envelope.
    Diagram_1      max_diag;

    upper_envelope_2 (&(circles[0]), &(circles[4]),

```

```
        max_diag);  
print_diagram (max_diag);  
  
return (0);  
}
```

Envelopes of Curves in 2D

Reference Manual

Ron Wein

Introduction

This package consists of functions that compute the lower (or upper) envelope of a set of arbitrary curves in 2D. The output is represented as an envelope diagram, namely a subdivision of the x -axis into intervals, such that the identity of the curves that induce the envelope over each interval is unique.

CGAL::lower_envelope_2

```
#include <CGAL/envelope_2.h>
```

```
template<class InputIterator, class EnvelopeDiagram>
```

```
void lower_envelope_2( InputIterator begin, InputIterator end, EnvelopeDiagram& diag)
```

Computes the lower envelope of a set of curves in \mathbb{R}^2 , as given by the range $[begin, end)$. The lower envelope is represented using the output minimization diagram *diag*, which must be a model of the *EnvelopeDiagram_1* concept.

Precondition: The value-type of *InputIterator* is *EnvelopeDiagram::Traits_2::Curve_2*.

CGAL::upper_envelope_2

```
#include <CGAL/envelope_2.h>
```

```
template<class InputIterator, class EnvelopeDiagram>
```

```
void upper_envelope_2( InputIterator begin, InputIterator end, EnvelopeDiagram& diag)
```

Computes the upper envelope of a set of curves in \mathbb{R}^2 , as given by the range $[begin, end)$. The upper envelope is represented using the output maximization diagram *diag*, which must be a model of the *EnvelopeDiagram_1* concept.

Precondition: The value-type of *InputIterator* is *EnvelopeDiagram::Traits_2::Curve_2*.

CGAL::lower_envelope_x_monotone_2

```
#include <CGAL/envelope_2.h>
```

```
template<class InputIterator, class EnvelopeDiagram>
void      lower_envelope_x_monotone_2( InputIterator begin,
                                       InputIterator end,
                                       EnvelopeDiagram& diag)
```

Computes the lower envelope of a set of x -monotone curves in \mathbb{R}^2 , as given by the range $[begin, end)$. The lower envelope is represented using the output minimization diagram *diag*, which must be a model of the *EnvelopeDiagram_1* concept.
Precondition: The value-type of *InputIterator* is *EnvelopeDiagram::X_monotone_curve_2*.

CGAL::upper_envelope_x_monotone_2

```
#include <CGAL/envelope_2.h>
```

```
template<class InputIterator, class EnvelopeDiagram>
void      upper_envelope_x_monotone_2( InputIterator begin,
                                       InputIterator end,
                                       EnvelopeDiagram& diag)
```

Computes the upper envelope of a set of x -monotone curves in \mathbb{R}^2 , as given by the range $[begin, end)$. The upper envelope is represented using the output maximization diagram *diag*, which must be a model of the *EnvelopeDiagram_1* concept.
Precondition: The value-type of *InputIterator* is *EnvelopeDiagram::X_monotone_curve_2*.

EnvelopeDiagram_1

Definition

This concept defines the representation of an envelope diagram of a set of planar curve. The *envelope diagram* is a subdivision of the x -axis into 0-dimensional cells (*vertices*) and 1-dimensional cells (*edges*), such that the identity of the curves that induce the lower envelope (or the upper envelope) over each cell is fixed.

A vertex in an envelope diagram is therefore associated with a point on the envelope, and corresponds to either a curve endpoint or to an intersection point of two (or more) curves. Therefore each vertex is associated with a set of x -monotone curves that induce the envelope over this point. Each vertex is incident to two edges, one lying to its left and the other to its right.

An edge in the envelope diagram represents a continuous portion of the x -axis, and is associated with a (possibly empty) set of curves that induce the envelope over this portion of the x -axis. An edge may be bounded by two vertices, one to its left and the other to its right. However, the diagram contains two unbounded edges, its *leftmost* edge, representing the interval $(-\infty, x_l)$, and its *rightmost* edge, representing the interval (x_r, ∞) , where x_l and x_r are the x -coordinates of the leftmost and the rightmost vertices in the diagram, respectively. Note that a diagram may contain no vertices at all, in which case it comprises a single edge.

Note that any model of the EnvelopeDiagram_1 concept must define a geometric traits class, which in turn defines the *Point_2* and *X_monotone_curve_2* types defined with the diagram features.

Types

<i>EnvelopeDiagram_1:: Traits_2</i>	the geometric traits class.
<i>typedef Traits_2:: Point_2</i>	
<i>Point_2;</i>	the point type.
<i>typedef Traits_2:: X_monotone_curve_2</i>	
<i>X_monotone_curve_2;</i>	the x -monotone curve type.
<i>EnvelopeDiagram_1:: Size</i>	the size type (convertible to <i>size_t</i>).
<i>EnvelopeDiagram_1:: Curve_const_iterator</i>	an iterator for the x -monotone curves that induce a diagram feature. Its value-type is <i>X_monotone_curve_2</i> .
<i>EnvelopeDiagram_1:: Vertex</i>	the vertex type, a model of the concept <i>EnvelopeDiagramVertex</i> .
<i>EnvelopeDiagram_1:: Edge</i>	the edge type, a model of the concept <i>EnvelopeDiagramEdge</i> .
<i>EnvelopeDiagram_1:: Vertex_handle</i>	a handle to a diagram vertex.
<i>EnvelopeDiagram_1:: Vertex_const_handle</i>	a non-mutable handle to a diagram vertex.

<i>EnvelopeDiagram_1:: Edge_handle</i>	a handle to a diagram edge.
<i>EnvelopeDiagram_1:: Edge_const_handle</i>	a non-mutable handle to a diagram edge.

Creation

<i>EnvelopeDiagram_1 diag;</i>	constructs an empty diagram containing one unbounded edge, which corresponds to the entire plane and has no x -monotone curves that are associated with it.
--------------------------------	---

<i>EnvelopeDiagram_1 diag(Self other);</i>	copy constructor.
---	-------------------

Access Functions

<i>Edge_const_handle</i>	<i>diag.leftmost()</i>	returns the leftmost edge of the diagram (a non-const version is also available).
--------------------------	------------------------	---

<i>Edge_const_handle</i>	<i>diag.rightmost()</i>	returns the rightmost edge of the diagram (a non-const version is also available).
--------------------------	-------------------------	--

Modifiers

<i>void</i>	<i>diag.set_leftmost(Edge_const_handle e)</i>	sets the leftmost edge of the diagram to be e .
-------------	--	---

<i>void</i>	<i>diag.set_rightmost(Edge_const_handle e)</i>	sets the rightmost edge of the diagram to be e .
-------------	---	--

<i>Vertex_handle</i>	<i>diag.new_vertex(Point_2 p)</i>	creates a new diagram vertex, associated with the point p .
----------------------	------------------------------------	---

<i>Edge_handle</i>	<i>diag.new_edge()</i>	creates a new diagram edge.
--------------------	------------------------	-----------------------------

<i>void</i>	<i>diag.delete_vertex(Vertex_handle v)</i>	deletes the given vertex v .
-------------	---	--------------------------------

<i>void</i>	<i>diag.delete_edge(Edge_handle e)</i>	deletes the given edge e .
-------------	---	------------------------------

EnvelopeDiagramVertex (page [2267](#))

EnvelopeDiagramEdge (page [2269](#))

EnvelopeDiagramVertex

Definition

A vertex record in an envelope diagram. It is always associated with a point on the lower (upper) envelope of a non-empty set of curves. A vertex is also associated with a set of x -monotone curves that induce the envelope over this point. It is incident to two edges, one lying to its left and the other to its right.

Types

<i>EnvelopeDiagramVertex:: Size</i>	the size type (convertible to <i>size_t</i>).
<i>EnvelopeDiagramVertex:: Edge</i>	the corresponding diagram-edge type.
<i>EnvelopeDiagramVertex:: Point_2</i>	the point type associated with the vertex.
<i>EnvelopeDiagramVertex:: X_monotone_curve_2</i>	the x -monotone curve type.

Creation

<i>EnvelopeDiagramVertex v;</i>	default constructor.
<i>EnvelopeDiagramVertex v(other);</i>	copy constructor.
<i>EnvelopeDiagramVertex v(Point_2 p);</i>	constructs a vertex associated with the given point p .

Access Functions

<i>Point_2</i>	<i>v.point()</i>	returns the point associated with v .
<i>Size</i>	<i>v.number_of_curves()</i>	returns the number of x -monotone curves associated with v .
<i>Curve_const_iterator</i>	<i>v.curves_begin()</i>	return an iterator for the first x -monotone curve associated with v .
<i>Curve_const_iterator</i>	<i>v.curves_end()</i>	return a past-the-end iterator for the x -monotone curves associated with v .
<i>Edge_const_handle</i>	<i>v.left()</i>	returns the edge lying to v 's left.
<i>Edge_const_handle</i>	<i>v.right()</i>	returns the edge lying to v 's right.

Modifiers

<i>void</i>	<i>v.set_point(Point_2 p)</i>	associates the point <i>p</i> with <i>v</i> .
<i>void</i>	<i>v.clear_curves()</i>	clears the set of curves associated with <i>v</i> .
<i>void</i>	<i>v.add_curve(X_monotone_curve_2 cv)</i>	adds the <i>x</i> -monotone curve <i>cv</i> to the set of curves associated with <i>v</i> .
<i>void</i>	<i>v.add_curves(Curve_const_iterator begin, Curve_const_iterator end)</i>	adds the given range of <i>x</i> -monotone curves to the set of curves associated with <i>v</i> .
<i>void</i>	<i>v.set_left(Edge_const_handle e)</i>	sets the edge lying to the left of <i>v</i> to be <i>e</i> .
<i>void</i>	<i>v.set_right(Edge_const_handle e)</i>	sets the edge lying to the right of <i>v</i> to be <i>e</i> .

EnvelopeDiagramEdge

Definition

An edge record in an envelope diagram, which represents a continuous portion of the x -axis. It is associated with a (possibly empty) set of curves that induce the envelope over this portion of the x -axis. Note that all curves in this set overlap over the interval represented by the edge.

Types

<i>EnvelopeDiagramEdge:: Size</i>	the size type (convertible to <i>size_t</i>).
<i>EnvelopeDiagramEdge:: Vertex</i>	the corresponding diagram-vertex type.
<i>EnvelopeDiagramEdge:: X_monotone_curve_2</i>	the x -monotone curve type.

Creation

<i>EnvelopeDiagramEdge e;</i>	default constructor.
<i>EnvelopeDiagramEdge e(other);</i>	copy constructor.

Access Functions

<i>Size</i>	<i>e.number_of_curves()</i>	returns the number of x -monotone curves associated with e .
<i>bool</i>	<i>e.is_empty()</i>	returns whether e represents an empty interval — namely, whether the set of x -monotone curves associated with it is empty.
<i>X_monotone_curve_2</i>	<i>e.curve()</i>	returns a representative x -monotone curve associated with e . <i>Precondition:</i> e does not represent an empty interval.
<i>Curve_const_iterator</i>	<i>e.curves_begin()</i>	return an iterator for the first x -monotone curve associated with e .
<i>Curve_const_iterator</i>	<i>e.curves_end()</i>	return a past-the-end iterator for the x -monotone curves associated with e .
<i>Vertex_const_handle</i>	<i>e.left()</i>	returns the vertex lying to e 's left. <i>Precondition:</i> e is not the leftmost edge in the diagram.
<i>Vertex_const_handle</i>	<i>e.right()</i>	returns the vertex lying to e 's right. <i>Precondition:</i> e is not the rightmost edge in the diagram.

Modifiers

<i>void</i>	<i>e.clear_curves()</i>	clears the set of curves associated with <i>e</i> .
<i>void</i>	<i>e.add_curve(X_monotone_curve_2 cv)</i>	
		adds the <i>x</i> -monotone curve <i>cv</i> to the set of curves associated with <i>e</i> .
<i>void</i>	<i>e.add_curves(Curve_const_iterator begin, Curve_const_iterator end)</i>	
		adds the given range of <i>x</i> -monotone curves to the set of curves associated with <i>e</i> .
<i>void</i>	<i>e.set_left(Vertex_const_handle v)</i>	
		sets the vertex lying to the left of <i>e</i> to be <i>v</i> .
<i>void</i>	<i>e.set_right(Vertex_const_handle v)</i>	
		sets the vertex lying to the right of <i>e</i> to be <i>v</i> .

CGAL::Env_default_diagram_1<Traits>

Definition

This class is the default envelope-diagram class used by envelope functions to represent the minimization or the maximization diagram of a set of curves. It represents the diagram as a doubly-linked list of interleaved vertices and edges. Thus, all operations provided by the envelope diagram take constant time, and the space needed to store the diagram class is linear in the complexity of the envelope.

The envelope-diagram class is parameterized by a traits class, which is a model of the *ArrangementXMonotoneTraits_2* concept, in case we handle only envelopes of *x*-monotone curves, or of the refined *ArrangementTraits_2* concept in case we handle arbitrary planar curves.

34.1 Introduction

A continuous surface S in \mathbb{R}^3 is called *xy-monotone*, if every line parallel to the z -axis intersects it at a single point at most. For example, the sphere $x^2 + y^2 + z^2 = 1$ is *not* *xy-monotone* as the z -axis intersects it at $(0, 0, -1)$ and at $(0, 0, 1)$; however, if we use the *xy*-plane to split it to an upper hemisphere and a lower hemisphere, these two hemispheres are *xy-monotone*.

An *xy-monotone* surface can therefore be represented as a bivariate function $z = S(x, y)$, defined over some continuous range $R_S \subseteq \mathbb{R}^2$. Given a set $\mathcal{S} = \{S_1, S_2, \dots, S_n\}$ of *xy-monotone* surfaces, their *lower envelope* is defined as the point-wise minimum of all surfaces. Namely, the lower envelope of the set \mathcal{S} can be defined as the following function:

$$\mathcal{L}_{\mathcal{S}}(x, y) = \min_{1 \leq k \leq n} \bar{S}_k(x, y) ,$$

where we define $\bar{S}_k(x, y) = S_k(x, y)$ for $(x, y) \in R_{S_k}$, and $\bar{S}_k(x, y) = \infty$ otherwise.

Similarly, the *upper envelope* of \mathcal{S} is the point-wise maximum of the *xy-monotone* surfaces in the set:

$$\mathcal{U}_{\mathcal{S}}(x, y) = \max_{1 \leq k \leq n} \underline{S}_k(x, y) ,$$

where in this case $\underline{S}_k(x, y) = -\infty$ for $(x, y) \notin R_{S_k}$.

Given a set of xy -monotone surfaces \mathcal{S} , the *minimization diagram* of \mathcal{S} is a subdivision of the xy -plane into cells, such that the identity of the surfaces that induce the lower diagram over a specific cell of the subdivision (be it a face, an edge, or a vertex) is the same. In non-degenerate situation, a face is induced by a single surface (or by no surfaces at all, if there are no xy -monotone surfaces defined over it), an edge is induced by a single surface and corresponds to its projected boundary, or by two surfaces and corresponds to their projected intersection curve, and a vertex is induced by a single surface and corresponds to its projected boundary point, or by three surfaces and corresponds to their projected intersection point. The *maximization diagram* is symmetrically defined for upper envelopes. In the rest of this chapter, we refer to both these diagrams as *envelope diagrams*.

It is easy to see that an envelope diagram is no more than a planar arrangement (see Chapter 30), represented using an extended DCEL structure, such that every DCEL record (namely each face, halfedge and vertex) stores an additional container of its originators: the xy -monotone surfaces that induce this feature.

Lower and upper envelopes can be efficiently computed using a divide-and-conquer approach. First note that the envelope diagram for a single xy -monotone curve S_k is trivial to compute: we project the boundary of its range of definition R_{S_k} onto the xy -plane, and label the faces it induces accordingly. Given a set \mathcal{D} of (non necessarily xy -monotone) surfaces in \mathbb{R}^3 , we subdivide each surface into a finite number of weakly xy -monotone surfaces,¹ and obtain the set \mathcal{S} . Then, we split the set into two disjoint subsets \mathcal{S}_1 and \mathcal{S}_2 , and we compute their envelope diagrams recursively. Finally, we merge the diagrams, and we do this by overlaying them and then applying some post-processing on the resulting diagram. The post-processing stage is non-trivial and involves the projection of intersection curves onto the xy -plane — see [Mey06] for more details.

34.2 The Envelope-Traits Concept

The implementation of the envelope-computation algorithm is generic and can handle arbitrary surfaces. It is parameterized with a traits class, which defines the geometry of surfaces it handles, and supports all the necessary functionality on these surfaces, and on their projections onto the xy -plane. The traits class must model the *EnvelopeTraits_3* concept, the details of which are given below.

As the representation of envelope diagrams is based on 2D arrangements, and the envelop-computation algorithm employs overlay of planar arrangements, the *EnvelopeTraits_3* refines the *ArrangementXMonotoneTraits_2* concept. Namely, a model of this concept must define the planar types *Point_2* and *X_monotone_curve_2* and support basic operations on them, as listed in Section 30.6. Moreover, it must define the spacial types *Surface_3* and *Xy_monotone_surface_3* (in practice, these two types may be the same). Any model of the envelope-traits concept must also support the following operations on these spacial types:

- Subdivide a given surface into continuous xy -monotone surfaces. It is possible to disregard xy -monotone surfaces that do not contribute to the surface envelope at this stage (for example, if we are given a sphere, it is possible to return just its lower hemisphere if we are interested in the lower envelope; the upper hemisphere is obviously redundant).
- Given an xy -monotone surface S , construct all planar curves that form the boundary of the vertical projection S 's boundary onto the xy -plane.

This operation is used at the bottom of the recursion to build the minimization diagram of a single xy -monotone surface.

- Construct all geometric entities that comprise the projection (onto the xy -plane) of the intersection between two xy -monotone surfaces S_1 and S_2 . These entities may be:

¹We consider *vertical* surfaces, namely patches of planes that are perpendicular to the xy -plane, as *weakly* xy -monotone, to handle degenerate inputs properly.

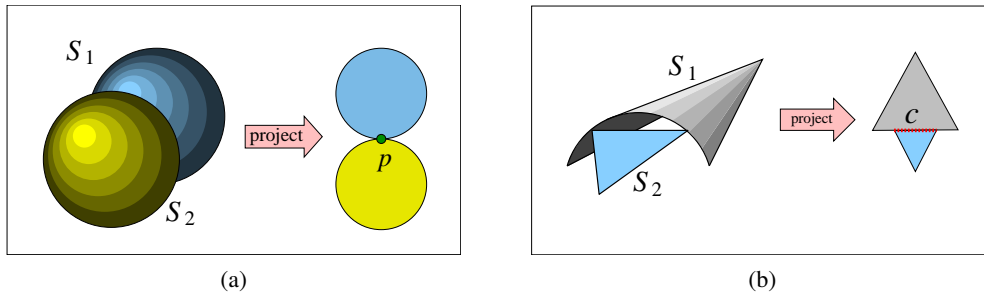

Figure 34.1: (a) The spheres S_1 and S_2 have only one two-dimensional point p in their common xy -definition range. They do not necessarily intersect over this point, and the envelope-construction algorithm needs to determine their relative z -order over p . (b) The z -order of the surfaces S_1 and S_2 should be determined over the x -monotone curve c . The comparison is performed over the *interior* of c , excluding its endpoints.

- A planar curve, which is the projection of an 3D intersection curve of S_1 and S_2 (for example, the intersection curve between two spheres is a 3D circle, which becomes an ellipse when projected onto the xy -plane). In many cases it is also possible to indicate the multiplicity of the intersection: if it is odd, the two surfaces intersect transversely and change their relative z -positions on either side of the intersection curve; if it is even, they maintain their relative z -position. Providing the multiplicity information is optional. When provided, it is used by the algorithm to determine the relative order of S_1 and S_2 on one side of their intersection curve when their order on the other side of that curve is known, thus improving the performance of the algorithm.
- A point, induces by the projection of a tangency point of S_1 and S_2 , *or* by the projection of a vertical intersection curve onto the xy -plane.

Needless to say, the set of intersection entities may be empty in case S_1 and S_2 do not intersect.

- Given two xy -monotone surfaces S_1 and S_2 , and a planar point $p = (x_0, y_0)$ that lies in their common xy -definition range, determine the z -order of S_1 and S_2 over p , namely compare $S_1(x_0, y_0)$ and $S_2(x_0, y_0)$. This operation is used only in degenerate situations, in order to determine the surface inducing the envelope over a vertex (see Figure 34.1(a) for an illustration of a situation when this operation is used).
- Given two xy -monotone surfaces S_1 and S_2 , and a planar x -monotone curve c , which is a part of their projected intersection, determine the z -order of S_1 and S_2 immediately above (or, similarly, immediately below) the curve c . Note that c is a planar x -monotone curve, and we refer to the region above (or below) it in the *plane*. If c is a vertical curve, we regard the region to its left as lying above it, and the region to its right as lying below it.

This operation is used by the algorithm to determine the surface that induce the envelope over a face incident to c .

- Given two xy -monotone surfaces S_1 and S_2 , and a planar x -monotone curve c , which fully lies in their common xy -definition range, and such that S_1 and S_2 do not intersect over the interior of c , determine the relative z -order of s_1 and s_2 over the interior of c . Namely, we compare $S_1(x_0, y_0)$ and $S_2(x_0, y_0)$ for some point (x_0, y_0) on c .

This operation is used by the algorithm to determine which surface induce the envelope over an edge associated with the x -monotone curve c , or of a face incident to c , in situations where the previous predicate cannot be used, as c is *not* an intersection curve of S_1 and S_2 (see Figure 34.1(b) for an illustration of a situation where this operation is used).

The package currently contains a traits class for named *Env_triangle_traits_3*<Kenrel> handling 3D triangles, and another named *Env_sphere_traits_3*<ConicTraits> for 3D spheres, based on geometric operations on conic curves (ellipses). In addition, the package includes a traits-class decorator that enables users to attach external (non-geometric) data to surfaces. The usage of the various traits classes is demonstrated in the next section.

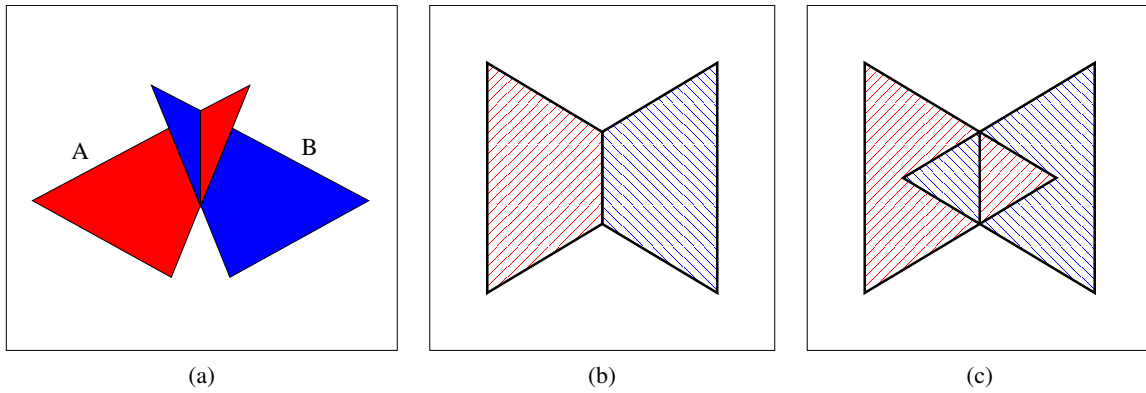

Figure 34.2: (a) Two triangles in \mathbb{R}^3 , as given in *envelope_triangles.cpp*. (b) Their lower envelope. (c) Their upper envelope.

34.3 Examples

34.3.1 Example for Envelope of Triangles

The following example shows how to use the *envelope-traits* class for 3D triangles and how to traverse the envelope diagram. It constructs the lower and upper envelopes of the two triangles, as depicted in Figure 34.2(a) and prints the triangles that induce each face and each edge in the output diagrams. For convenience, we use the traits-class decorator *Env_surface_data_traits_3* to label the triangles. When printing the diagrams, we just output the labels of the triangles:

```
#include <CGAL/Gmpq.h>
#include <CGAL/Cartesian.h>
#include <CGAL/Env_triangle_traits_3.h>
#include <CGAL/Env_surface_data_traits_3.h>
#include <CGAL/envelope_3.h>
#include <iostream>
#include <list>

typedef CGAL::Gmpq                               Number_type;
typedef CGAL::Cartesian<Number_type>              Kernel;
typedef CGAL::Env_triangle_traits_3<Kernel>        Traits_3;
typedef Kernel::Point_3                           Point_3;
typedef Traits_3::Surface_3                        Triangle_3;
typedef CGAL::Env_surface_data_traits_3<Traits_3, char> Data_traits_3;
typedef Data_traits_3::Surface_3                   Data_triangle_3;
typedef CGAL::Envelope_diagram_2<Data_traits_3>    Envelope_diagram_2;

/* Auxiliary function - print the features of the given envelope diagram.
 */
void print_diagram (const Envelope_diagram_2& diag)
{
    // Go over all arrangement faces.
    Envelope_diagram_2::Face_const_iterator fit;
    Envelope_diagram_2::Ccb_halfedge_const_circulator ccb;
```

```

Envelope_diagram_2::Surface_const_iterator      sit;

for (fit = diag.faces_begin(); fit != diag.faces_end(); ++fit)
{
    // Print the face boundary.
    if (fit->is_unbounded())
    {
        std::cout << "[Unbounded face]";
    }
    else
    {
        // Print the vertices along the outer boundary of the face.
        ccb = fit->outer_ccb();
        std::cout << "[Face]  ";
        do
        {
            std::cout << ' (' << ccb->target()->point() << " )  ";
            ++ccb;
        } while (ccb != fit->outer_ccb());
    }

    // Print the labels of the triangles that induce the envelope on this
    face.
    std::cout << "-->  " << fit->number_of_surfaces()
               << " triangles:";

    for (sit = fit->surfaces_begin(); sit != fit->surfaces_end(); ++sit)
        std::cout << ' ' << sit->data();
    std::cout << std::endl;
}

// Go over all arrangement edges.
Envelope_diagram_2::Edge_const_iterator      eit;

for (eit = diag.edges_begin(); eit != diag.edges_end(); ++eit)
{
    // Print the labels of the triangles that induce the envelope on this
    edge.
    std::cout << "[Edge]  (" << eit->source()->point()
               << " )  (" << eit->target()->point()
               << " )  -->  " << eit->number_of_surfaces()
               << " triangles:";

    for (sit = eit->surfaces_begin(); sit != eit->surfaces_end(); ++sit)
        std::cout << ' ' << sit->data();
    std::cout << std::endl;
}

return;
}

/* The main program: */
int main ()
{

```

```

// Construct the input triangles, makred A and B.
std::list<Data_triangle_3>   triangles;

triangles.push_back (Data_triangle_3 (Triangle_3 (Point_3 (0, 0, 0),
                                                         Point_3 (0, 6, 0),
                                                         Point_3 (5, 3, 4)),
                                     'A'));
triangles.push_back (Data_triangle_3 (Triangle_3 (Point_3 (6, 0, 0),
                                                         Point_3 (6, 6, 0),
                                                         Point_3 (1, 3, 4)),
                                     'B'));

// Compute and print the minimization diagram.
Envelope_diagram_2          min_diag;

CGAL::lower_envelope_3 (triangles.begin(), triangles.end(),
                       min_diag);

std::cout << std::endl << "The minimization diagram:" << std::endl;
print_diagram (min_diag);

// Compute and print the maximization diagram.
Envelope_diagram_2          max_diag;

CGAL::upper_envelope_3 (triangles.begin(), triangles.end(),
                       max_diag);

std::cout << std::endl << "The maximization diagram:" << std::endl;
print_diagram (max_diag);

return (0);
}

```

34.3.2 Example for Envelope of Spheres

The next example demonstrates how to instantiate and use the envelope-traits class for spheres, based on the *Arr_conic_traits_2* class that handles the projected intersection curves. The program reads a set of spheres from an input file and constructs their lower envelope:

```

#include <CGAL/basic.h>

#ifndef CGAL_USE_CORE
#include <iostream>
int main()
{
    std::cout << "Sorry, this example needs CORE ..." << std::endl;
    return 0;
}
#else

```

```

#include <CGAL/Cartesian.h>
#include <CGAL/CORE_algebraic_number_traits.h>
#include <CGAL/Arr_conic_traits_2.h>
#include <CGAL/Env_sphere_traits_3.h>
#include <CGAL/envelope_3.h>
#include <CGAL/Timer.h>
#include <iostream>
#include <list>

typedef CGAL::CORE_algebraic_number_traits          Nt_traits;
typedef Nt_traits::Rational                        Rational;
typedef Nt_traits::Algebraic                       Algebraic;
typedef CGAL::Cartesian<Rational>                  Rat_kernel;
typedef Rat_kernel::Point_3                        Rat_point_3;
typedef CGAL::Cartesian<Algebraic>                  Alg_kernel;

typedef CGAL::Arr_conic_traits_2<Rat_kernel, Alg_kernel, Nt_traits>
                                                    Conic_traits_2;

typedef CGAL::Env_sphere_traits_3<Conic_traits_2>   Traits_3;
typedef Traits_3::Surface_3                        Sphere_3;
typedef CGAL::Envelope_diagram_2<Traits_3>          Envelope_diagram_2;

int main(int argc, char **argv)
{
    // Get the name of the input file from the command line, or use the
    // default
    // fan_grids.dat file if no command-line parameters are given.
    const char * filename = (argc > 1) ? argv[1] : "spheres.dat";

    // Open the input file.
    std::ifstream      in_file(filename);

    if (! in_file.is_open())
    {
        std::cerr << "Failed to open " << filename << " ..." << std::endl;
        return 1;
    }

    // Read the spheres from the file.
    // The input file format should be (all coordinate values are
    // integers):
    // <n>                                // number of spheres.
    // <x_1> <y_1> <x_1> <R_1>             // center and squared radius of
    // sphere #1.
    // <x_2> <y_2> <x_2> <R_2>             // center and squared radius of
    // sphere #2.
    // : : : :
    // <x_n> <y_n> <x_n> <R_n>             // center and squared radius of
    // sphere #n.
    int          n = 0;
    std::list<Sphere_3> spheres;
    int          x = 0, y = 0, z = 0, sqr_r = 0;

```

```

int                                     i;

in_file >> n;
for (i = 0; i < n; ++i)
{
    in_file >> x >> y >> z >> sqr_r;
    spheres.push_back(Sphere_3(Rat_point_3(x, y, z), Rational(sqr_r)));
}
in_file.close();

// Compute the lower envelope.
Envelope_diagram_2    min_diag;
CGAL::Timer           timer;

std::cout << "Constructing the lower envelope of "
           << n << " spheres." << std::endl;

timer.start();
CGAL::lower_envelope_3(spheres.begin(), spheres.end(), min_diag);
timer.stop();

// Print the dimensions of the minimization diagram.
std::cout << "V = " << min_diag.number_of_vertices()
           << ",   E = " << min_diag.number_of_edges()
           << ",   F = " << min_diag.number_of_faces() << std::endl;

std::cout << "Construction took " << timer.time()
           << " seconds." << std::endl;

return 0;
}
#endif

```

File: examples/Envelope_3/envelope_spheres.cpp

34.3.3 Example for Envelope of Planes

The next example demonstrates how to instantiate and use the envelope-traits class for planes, based on the *Arr_linear_traits_2* class that handles infinite linear objects such as lines and rays.

```

#include <CGAL/Gmpq.h>
#include <CGAL/Cartesian.h>
#include <CGAL/Env_plane_traits_3.h>
#include <CGAL/envelope_3.h>
#include <iostream>
#include <list>

typedef CGAL::Gmpq                               Number_type;
typedef CGAL::Cartesian<Number_type>             Kernel;
typedef Kernel::Plane_3                           Plane_3;

```

```

typedef CGAL::Env_plane_traits_3<Kernel> Traits_3;
typedef Traits_3::Surface_3 Surface_3;
typedef CGAL::Envelope_diagram_2<Traits_3>
    Envelope_diagram_2;

/* Auxiliary function - print the features of the given envelope diagram.
   */
void print_diagram (const Envelope_diagram_2& diag)
{
    // Go over all arrangement faces.
    Envelope_diagram_2::Face_const_iterator fit;
    Envelope_diagram_2::Ccb_halfedge_const_circulator ccb;

Envelopes of Surfaces in 3D

Reference Manual

Dan Halperin, Michal Meyerovitch, Ron Wein and Baruch Zukerman

Introduction

This package consists of functions that compute the lower (or upper) envelope of a set of arbitrary surfaces in 3D. The output is represented as an 2D envelope diagram — a planar subdivision such that the identity of the surfaces that induce the envelope over each diagram cell is unique.

CGAL::lower_envelope_3

```
#include <CGAL/envelope_3.h>
```

```
template<class InputIterator, class Traits>  
void lower_envelope_3( InputIterator begin,  
                      InputIterator end,  
                      Envelope_diagram_2<Traits>& diag)
```

Computes the lower envelope of a set of surfaces in \mathbb{R}^3 , as given by the range $[begin, end)$. The lower envelope is represented using the output minimization diagram *diag*.

Precondition: The value-type of *InputIterator* is *Traits::Surface_3*.

CGAL::upper_envelope_3

```
#include <CGAL/envelope_3.h>
```

```
template<class InputIterator, class Traits>  
void      upper_envelope_3( InputIterator begin,  
                           InputIterator end,  
                           Envelope_diagram_2<Traits>& diag)
```

Computes the upper envelope of a set of surfaces in \mathbb{R}^3 , as given by the range $[begin, end)$. The upper envelope is represented using the output maximization diagram *diag*.

Precondition: The value-type of *InputIterator* is *Traits::Surface_3*.

CGAL::lower_envelope_xy_monotone_3

```
#include <CGAL/envelope_3.h>
```

```
template<class InputIterator, class Traits>
```

```
void lower_envelope_xy_monotone_3( InputIterator begin,  
                                   InputIterator end,  
                                   Envelope_diagram_2<Traits>& diag)
```

Computes the lower envelope of a set of *xy*-monotone surfaces in \mathbb{R}^3 , as given by the range $[begin, end)$. The lower envelope is represented using the output minimization diagram *diag*.

Precondition: The value-type of *InputIterator* is *Traits::Xy_monotone_surface_3*.

CGAL::upper_envelope_xy_monotone_3

```
#include <CGAL/envelope_3.h>
```

```
template<class InputIterator, class Traits>
```

```
void          upper_envelope_xy_monotone_3( InputIterator begin,
                                             InputIterator end,
                                             Envelope_diagram_2<Traits>& diag)
```

Computes the upper envelope of a set of *xy*-monotone surfaces in \mathbb{R}^3 , as given by the range $[begin, end)$. The lower envelope is represented using the output maximization diagram *diag*.

Precondition: The value-type of *InputIterator* is *Traits::Xy_monotone_surface_3*.

EnvelopeTraits_3

Definition

This concept defines the minimal set of geometric predicates and operations needed to compute the envelope of a set of arbitrary surfaces in \mathbb{R}^3 . It refines the *ArrangementXMonotoneTraits_2* concept. In addition to the *Point_2* and *X_monotone_curve_2* types and the *Has_boundary_category* category tag listed in the base concept, it also lists the *Surface_3* and *Xy_monotone_surface_3* types, which represent arbitrary surfaces and *xy*-monotone surfaces, respectively, and some constructions and predicates on these types. Note however, that these operations usually involve the projection of 3D objects onto the *xy*-plane.

Refines

ArrangementXMonotoneTraits_2

Types

<i>EnvelopeTraits_3:: Surface_3</i>	represents an arbitrary surface in \mathbb{R}^3 .
<i>EnvelopeTraits_3:: Xy_monotone_surface_3</i>	represents a weakly <i>xy</i> -monotone surface in \mathbb{R}^3 .

Functor Types

EnvelopeTraits_3:: Make_xy_monotone_3

provides the operator (templated by the *OutputIterator* type) :

- *OutputIterator operator()* (*Surface_3 S*, *bool is_lower*, *OutputIterator oi*)
which subdivides the given surface *S* into *xy*-monotone parts and inserts them into the output iterator. The value of *is_lower* indicates whether we compute the lower or the upper envelope, so that *xy*-monotone surfaces that are irrelevant to the lower-envelope (resp. upper-envelope) computation may be discarded. The value-type of *OutputIterator* is *Xy_monotone_surface_3*. The operator returns a past-the-end iterator for the output sequence.

EnvelopeTraits_3:: Construct_projected_boundary_2

provides the operator (templated by the *OutputIterator* type) :

- *OutputIterator operator()* (*Xy_monotone_surface_3 s*, *OutputIterator oi*)
which computes all planar *x*-monotone curves and possibly isolated planar points that form the projection of the boundary of the given *xy*-monotone surface *s* onto the *xy*-plane, and inserts them into the output iterator. The value-type of *OutputIterator* is *Object*, where *Object* wraps either a *Point_2*, or a *pair*<*X_monotone_curve_2*, *Oriented_side*>. In the former case, the object represents an isolated point of the projected boundary. In the latter, more general, case the object represents an *x*-monotone boundary curve along with an enumeration value which is either *ON_NEGATIVE_SIDE* or *ON_POSITIVE_SIDE*, indicating whether the projection of the surface onto the *xy*-plane lies below or above this *x*-monotone curve, respectively. In degenerate case, namely when the surface itself is vertical, and its projection onto the plane is 1-dimensional, the *Oriented_side* value is *ON_ORIENTED_BOUNDARY*. The operator returns a past-the-end iterator for the output sequence.

EnvelopeTraits_3:: Construct_projected_intersections_2

provides the operator (templated by the *OutputIterator* type) :

- *OutputIterator operator()* (*Xy_monotone_surface_3* *s1*, *Xy_monotone_surface_3* *s2*, *OutputIterator* *oi*)
which computes the projection of the intersections of the *xy*-monotone surfaces *s1* and *s2* onto the *xy*-plane, and inserts them into the output iterator. The value-type of *OutputIterator* is *Object*, where each *Object* either wraps a *pair*<*X_monotone_curve_2*, *Multiplicity*> instance, which represents a projected intersection curve with its multiplicity (in case the multiplicity is undefined or not known, it should be set to 0) or an *Point_2* instance, representing the projected image of a degenerate intersection (the projection of an isolated intersection point, or of a vertical intersection curve). The operator returns a past-the-end iterator for the output sequence.

EnvelopeTraits_3:: Compare_z_at_xy_3

provides the operators :

- *Comparison_result operator()* (*Point_2* *p*, *Xy_monotone_surface_3* *s1*, *Xy_monotone_surface_3* *s2*)
which determines the relative *z*-order of the two given *xy*-monotone surfaces at the *xy*-coordinates of the point *p*, with the precondition that both surfaces are defined over *p*. Namely, it returns the comparison result of $s_1(p)$ and $s_2(p)$.
- *Comparison_result operator()* (*X_monotone_curve_2* *c*, *Xy_monotone_surface_3* *s1*, *Xy_monotone_surface_3* *s2*)
which determines the relative *z*-order of the two given *xy*-monotone surfaces over the interior of a given *x*-monotone curve *c*, with the precondition that *c* is fully contained in the *xy*-definition range of both *s1* and *s2*, and that the surfaces do not intersect over *c*. The functor should therefore return the comparison result of $s_1(p')$ and $s_2(p')$ for some point p' in the interior of *c*.
- *Comparison_result operator()* (*Xy_monotone_surface_3* *s1*, *Xy_monotone_surface_3* *s2*)
which determines the relative *z*-order of the two given unbounded *xy*-monotone surfaces, which are defined over the entire *xy*-plane and have no boundary, with the precondition that the surfaces do not intersect at all. The functor should therefore return the comparison result of $s_1(p)$ and $s_2(p)$ for some planar point $p \in \mathbb{R}^2$. This operator is required iff the category tag *Has_boundary_category* is defined as *Tag_true*.

EnvelopeTraits_3:: Compare_z_at_xy_above_3

provides the operator :

- *Comparison_result operator()* (*X_monotone_curve_2* *c*, *Xy_monotone_surface_3* *s1*, *Xy_monotone_surface_3* *s2*)
which determines the relative *z*-order of the two given *xy*-monotone surfaces immediately above their projected intersection curve *c* (a planar point *p* is *above* an *x*-monotone curve *c* if it is in the *x*-range of *c*, and lies to its left when the curve is traversed from its *xy*-lexicographically smaller endpoint to its larger endpoint). We have the precondition that both surfaces are defined “above” *c*, and their relative *z*-order is the same for some small enough neighborhood of points above *c*.

EnvelopeTraits_3:: Compare_z_at_xy_below_3

provides the operator :

- *Comparison_result operator()* (*X_monotone_curve_2 c*, *Xy_monotone_surface_3 s1*, *Xy_monotone_surface_3 s2*)
which determines the relative *z*-order of the two given *xy*-monotone surfaces immediately below their projected intersection curve *c* (a planar point *p* is *below* an *x*-monotone curve *c* if it is in the *x*-range of *c*, and lies to its right when the curve is traversed from its *xy*-lexicographically smaller endpoint to its larger endpoint). We have the precondition that both surfaces are defined “below” *c*, and their relative *z*-order is the same for some small enough neighborhood of points below *c*.

CGAL::Env_surface_data_traits_3<Traits,XyData,SData,Cnv>

CGAL::Env_triangle_traits_3<Kernel>

Definition

The traits class *Env_triangle_traits_3<Kernel>* models the *EnvelopeTraits_3* concept, and is used for the construction of lower and upper envelopes of triangles in the space. It is parameterized by a CGAL-kernel, which is parameterized in turn by a number type. The number type should support exact rational arithmetic, to avoid numerical errors and robustness problems. In particular, the number type should support the arithmetic operations $+$, $-$, \times , and \div without loss of precision. For optimal performance, we recommend instantiating the traits class with the predefined *Exact_predicates_exact_constructions_kernel* provided by CGAL. Using this kernel guarantees exactness and robustness, while it incurs only a minor overhead (in comparison to working with a fast, inexact number type) for most inputs.

Note that when we project the boundary of a triangle, or the intersection of two triangles, onto the *xy*-plane, we obtain line segments. Indeed, *Env_triangle_traits_3<Kernel>* inherits from the *Arr_segment_traits_2<Kernel>* traits class, and extends it by adding operations on 3D objects, namely spacial triangles. Note that the traits class does *not* define *Kernel::Triangle_3* as its surface (and *xy*-monotone surface) type, as one may expect. This is because the traits class needs to store extra data with the triangles in order to efficiently operate on them. Nevertheless, the nested *Xy_monotone_surface_3* and *Surface_3* types are however constructible from a *Kernel::Triangle_3* instance and are also convertible to a *Kernel::Triangle_3* object. Both types, *Xy_monotone_surface_3* and *Surface_3*, refer to the same class, as every triangle is (weakly) *xy*-monotone).

```
#include <CGAL/Env_triangle_traits_3.h>
```

EnvelopeTraits_3

Inherits From

Arr_segment_traits_2<Kernel>

CGAL::Env_sphere_traits_3<ConicTraits>

Definition

The traits class *Env_sphere_traits_3<ConicTraits>* models the *EnvelopeTraits_3* concept, and is used for the construction of lower and upper envelopes of spheres. Note that when projecting the intersection curve of two spheres (a circle in 3D) onto the *xy*-plane, the resulting curve is an ellipse. The traits class is therefore parameterized by an arrangement-traits class that is capable of handling conic curves — namely an instantiation of the *Arr_conic_traits_2* class-template — and inherits from it.

The conic-traits class defines a nested type named *Rat_kernel*, which is a geometric kernel parameterized by an exact rational type. *Env_sphere_traits_3<ConicTraits>* defines its *Surface_3* type to be constructible from *Rat_kernel::Sphere_3*. Namely, it can handle spheres whose center points have rational coordinates (i.e., of the type *Rat_kernel::FT*), and whose squared radius is also rational. The *Surface_3* type is also convertible to a *Rat_kernel::Sphere_3* object.

The *Xy_monotone_surface_3* type is the same as the nested *Surface_3* type. The traits-class simply ignores the upper hemisphere when it computes lower envelopes, and ignores the lower hemisphere when it computes upper envelopes.

```
#include <CGAL/Env_sphere_traits_3.h>
```

CGAL::Env_surface_data_traits_3<Traits,XyData,SData,Cnv>

Definition

The class *Env_surface_data_traits_3*<Traits,XyData,SData,Cnv> is a model of the *EnvelopeTraits_3* concept and serves as a decorator class that allows the extension of the surfaces defined by the base traits-class (the *Traits* parameter), which serves as a geometric traits-class (a model of the *EnvelopeTraits_3* concept), with extraneous (non-geometric) data fields.

The traits-class decorator extends the *Surface_3* and the *Xy_monotone_surface_3* types as detailed below. Each *Surface_3* object is associated with a single data field of type *SData*, and each *Xy_monotone_surface_3* object is associated with a single data field of type *XyData*. When a surface is subdivided into *xy*-monotone surfaces, its data field is converted using the conversion functor, which is specified by the *Cnv* template-parameter, and the resulting objects is copied to all *Xy_monotone_surface_3* objects induced by this surface. The conversion functor should provide an operator with the following prototype:

XyData operator() (*const SData& d*) *const*;

By default, the two data types are the same, so the conversion operator is trivial and just copies the data object:

SData = *XyData*

Cnv = *_Default_convert_functor*<*SData*,*XyData*>

#include <CGAL/Env_surface_data_traits_3.h>

Is Model for the Concepts

EnvelopeTraits_3

Types

typedef Traits *Base_traits_3*; the base traits-class.

typedef typename Base_traits_3::Surface_3

Base_surface_3; the base surface.

typedef typename Base_traits_3::Xy_monotone_surface_3

Base_xy_monotone_surface_3;

the base *xy*-monotone surface surface.

typedef Cnv *Convert*; the conversion functor.

typedef SData *Surface_data*; the type of data associated with surfaces.

typedef XyData *Xy_monotone_surface_data*;

the type of data associated with *xy*-monotone surfaces.

Inherits From

Base_traits_3

Class Env_surface_data_traits_3<Traits,XyData,SData,Cnv>::Surface_3

The *Surface_3* class nested within the surface-data traits extends the *Base_traits_3::Surface_3* type with an extra data field.

Inherits From

Base_surface_3

Creation

Env_surface_data_traits_3<Traits,XyData,SData,Cnv>::Surface_3 s;

default constructor.

Env_surface_data_traits_3<Traits,XyData,SData,Cnv>::Surface_3 s(Base_surface_3 base);

constructs surface from the given *base* surface with uninitialized data field.

*Env_surface_data_traits_3<Traits,XyData,SData,Cnv>::Surface_3 s(Base_surface_3 base,
Surface_data data)*

constructs surface from the given *base* surface with an attached *data* field.

Access Functions

<i>Surface_data</i>	<i>s.data()</i>	returns the data field (a non-const version, which returns a reference to the data object, is also available).
---------------------	-----------------	--

<i>void</i>	<i>s.set_data(Surface_data data)</i>	sets the data field.
-------------	---------------------------------------	----------------------

Class Env_surface_data_traits_3<Traits,XyData,SData,Cnv>::Xy_monotone_surface_3

The *Xy_monotone_surface_3* class nested within the surface-data traits extends the *Base_traits_3::Xy_monotone_surface_3* type with an extra data field.

Inherits From

Base_xy_monotone_surface_3

Creation

Arr_surface_data_traits_3<*Tr*,*XData*,*Mrg*,*CData*,*Cnv*>::*Xy_monotone_surface_3* *xys*;

default constructor.

Arr_surface_data_traits_3<*Tr*,*XData*,*Mrg*,*CData*,*Cnv*>::*Xy_monotone_surface_3* *xys*(*Base_xy_monotone_surface_3* *base*)

constructs an *xy*-monotone surface from the given *base* surface with uninitialized data field.

Arr_surface_data_traits_3<*Tr*,*XData*,*Mrg*,*CData*,*Cnv*>::*Xy_monotone_surface_3* *xys*(*Base_xy_monotone_surface_3* *base*,
Xy_monotone_surface_data *data*)

constructs an *x*-monotone surface from the given *base* *x*-monotone surface with an attached *data* field.

Access Functions

Xy_monotone_surface_data

xys.data()

returns the field (a non-const version, which returns a reference to the data object, is also available).

void

xys.set_data(*Xy_monotone_surface_data* *data*)

sets the data field.

CGAL::Env_plane_traits_3<Kernel>

Definition

The traits class *Env_plane_traits_3<Kernel>* models the *EnvelopeTraits_3* concept, and is used for the construction of lower and upper envelopes of planes and half planes in the space. It is parameterized by a CGAL-kernel model, which is parameterized in turn by a number type. The number type should support exact rational arithmetic, to avoid numerical errors and robustness problems. In particular, the number type should support the arithmetic operations $+$, $-$, \times , and \div without loss of precision. For optimal performance, we recommend instantiating the traits class with the predefined *Exact_predicates_exact_constructions_kernel* provided by CGAL. Using this kernel guarantees exactness and robustness, while it incurs only a minor overhead (in comparison to working with a fast, inexact number type) for most inputs.

Note that an entire plane has no boundaries, and the projection of a half-plane is an (unbounded) line. Naturally, rays and segments may occur as a result of overlaying projections of several half planes. Indeed, *Env_plane_traits_3<Kernel>* inherits from the *Arr_linear_traits_2<Kernel>* traits class, and extends it by adding operations on planes and half planes. The nested *Xy_monotone_surface_3* and *Surface_3* types refer to the same type. They are constructible from a *Kernel::Plane_3* in case of an entire plane, or from *Kernel::Plane_3* and *Kernel::Line_2* in case of a half-plane. The line orientation determines which half is considered.

```
#include <CGAL/Env_plane_traits_3.h>
```

EnvelopeTraits_3

Inherits From

Arr_linear_traits_2<Kernel>

CGAL::Envelope_diagram_2<EnvTraits>

Definition

The class-template *Envelope_diagram_2<EnvTraits>* represents the minimization diagram that corresponds to the lower envelope of a set of curves, or the maximization diagram that corresponds to their upper envelope. It is parameterized by a traits class that must be a model of the *EnvelopeTraits_3* concept, and is basically a planar arrangement of *x*-monotone curves, as defined by this traits class. These *x*-monotone curves are the projections of boundary curves of *xy*-monotone surfaces, or the intersection curves between such surfaces, onto the *xy*-plane. Thus, it is possible to traverse the envelope diagram using the methods inherited from the *Arrangement_2* class.

The envelope diagram extends the arrangement features (namely the vertices, halfedges, and faces), such that each feature stores a container of originators — namely, the *xy*-monotone surfaces (instances of the type *EnvTraits::Xy_monotone_surface_3*) that induce the lower envelope (or the upper envelope, in case of a maximization diagram) over this feature. The envelope diagram provides access methods to these originators.

```
#include <CGAL/envelope_3.h>
```

Inherits From

```
Arrangement_2<EnvTraits>
```

Types

```
typedef Envelope_diagram_2<EnvTraits>
```

```
Self;
typedef Arrangement_2<EnvTraits>
```

```
Base;
```

```
Envelope_diagram_2<EnvTraits>:: Surface_const_iterator
```

an iterator for the *xy*-monotone surfaces that induce a diagram feature. Its value-type is *EnvTraits::Xy_monotone_surface_3*.

Creation

```
Envelope_diagram_2<EnvTraits> diag;
```

constructs an empty diagram containing one unbounded face, which corresponds to the entire plane and has no originators.

```
Envelope_diagram_2<EnvTraits> diag( Self other);
```

copy constructor.

Envelope_diagram_2<EnvTraits> *diag*(*EnvTraits* **traits*);

constructs an empty diagram that uses the given *traits* instance for performing the geometric predicates.

Class *Envelope_diagram_2*<EnvTraits>::Vertex

Inherits From

Base::*Vertex*

Access Functions

size_t *v.number_of_surfaces()*

returns the number of *xy*-monotone surfaces that induce *v*.

Surface_const_iterator

v.surfaces_begin()

returns an iterator for the first *xy*-monotone surface that induces *v*.

Surface_const_iterator

v.surfaces_end()

returns a past-the-end iterator for the *xy*-monotone surfaces that induce *v*.

Xy_monotone_surface_3

v.surface()

returns the first *xy*-monotone surface that induce *v*.

Precondition: The number of surfaces is not 0.

Class *Envelope_diagram_2*<EnvTraits>::Halfedge

Inherits From

Base::*Halfedge*

Access Functions

size_t *e.number_of_surfaces()*

returns the number of *xy*-monotone surfaces that induce *e*.

Surface_const_iterator

e.surfaces_begin()

returns an iterator for the first *xy*-monotone surface that induces *e*.

Surface_const_iterator

e.surfaces_end() returns a past-the-end iterator for the *xy*-monotone surfaces that induce *e*.

Xy_monotone_surface_3

e.surface() returns the first *xy*-monotone surface that induce *e*.
Precondition: The number of surfaces is not 0.

Class Envelope_diagram_2<EnvTraits>::Face

Inherits From

Base::Face

Access Functions

size_t *f*.number_of_surfaces() returns the number of *xy*-monotone surfaces that induce *f*.

Surface_const_iterator

f.surfaces_begin() returns an iterator for the first *xy*-monotone surface that induces *f*.

Surface_const_iterator

f.surfaces_end() returns a past-the-end iterator for the *xy*-monotone surfaces that induce *f*.

Xy_monotone_surface_3

f.surface() returns the first *xy*-monotone surface that induce *f*.
Precondition: The number of surfaces is not 0.

This chapter describes the two dimensional triangulations of CGAL. Section 35.1 recalls the main definitions about triangulations. Sections 35.2 discusses the way two-dimensional triangulations are represented in CGAL. Section 35.3 presents the overall software design of the 2D triangulations package. The next sections present the different two dimensional triangulations classes available in CGAL : basic triangulations (section 35.4), Delaunay triangulations (Section 35.5), regular triangulations (Section 35.6), constrained triangulations (Section 35.7), and constrained Delaunay triangulations (Section 35.8). Section 35.9 describes a class which implements a constrained or constrained Delaunay triangulation with an additional data structure to describe how the constraints are refined by the edges of the triangulations. Section 35.10 describes a hierarchical data structure for fast point location queries. At last, Section 35.11 explains how the user can benefit from the flexibility of CGAL triangulations using customized classes for faces and vertices.

35.1 Definitions

A two dimensional triangulation can be roughly described as a set T of triangular facets such that :

- two facets either are disjoint or share a lower dimensional face (edge or vertex).
- the set of facets in T is connected for the adjacency relation.
- the domain U_T which is the union of facets in T has no singularity.

More precisely, a triangulation can be described as a simplicial complex. Let us first record a few definitions.

A simplicial complex is a set T of simplices such that

- any face of a simplex in T is a simplex in T
- two simplices in T either are disjoint or share a common sub-face.

The dimension d of a simplicial complex is the maximal dimension of its simplices.

A simplicial complex T is pure if any simplex of T is included in a simplex of T with maximal dimension.

Two simplexes in T with maximal dimension d are said to be adjacent if they share a $d - 1$ dimensional sub-face.

A simplicial complex is connected if the adjacency relation defines a connected graph over the set of simplices of T with maximal dimension.

The union U_T of all simplices in T is called the domain of T . A point p in the domain of T is said to singular if its surrounding in U_T is neither a topological ball nor a topological disc.

Then, a two dimensional triangulation can be described as a two dimensional simplicial complex that is pure, connected and without singularity.

Each facet of a triangulation can be given an orientation which in turn induces an orientation on the edges incident to that facet. The orientation of two adjacent facets are said to be consistent if they induce opposite orientations on their common incident edge. A triangulation is said to be orientable if the orientation of each facet can be chosen in such a way that all pairs of incident facets have consistent orientations.

The data structure underlying CGAL triangulations allows to represent the combinatorics of any orientable two dimensional triangulations without boundaries. On top of this data structure, the 2D triangulations classes take care of the geometric embedding of the triangulation and are designed to handle planar triangulations. The plane of the triangulation may be embedded in a higher dimensional space.

The triangulations of CGAL are complete triangulations which means that their domain is the convex hull of their vertices. Because any planar triangulation can be completed, this is not a real restriction. For instance, a triangulation of a polygonal region can be constructed and represented as a subset of a constrained triangulation in which the region boundary edges have been input as constrained edges (see Section 35.7, 35.8 and 35.9).

Strictly speaking, the term *face* should be used to design a face of any dimension, and the two-dimensional faces of a triangulation should be properly called *facets*. However, following a common usage, we hereafter often call *faces*, the facets of a two dimensional triangulation.

35.2 Representation

The set of faces

A 2D triangulation of CGAL can be viewed as a planar partition whose bounded faces are triangular and cover the convex hull of the set of vertices. The single unbounded face of this partition is the complementary of the convex hull. In many applications, such as Kirkpatrick's hierarchy or incremental Delaunay construction, it is convenient to deal with only triangular faces. Therefore, a fictitious vertex, called the *infinite vertex* is added to the triangulation as well as *infinite edges* and *infinite faces* incident to it.. Each infinite edge is incident to the infinite vertex and to a vertex of the convex hull. Each infinite face is incident to the infinite vertex and to a convex hull edge.

Therefore, each edge of the triangulation is incident to exactly two faces and the set of faces of a triangulation is topologically equivalent to a two-dimensional sphere. This extends to lower dimensional triangulations arising in degenerate cases or when the triangulations as less than three vertices. Including the infinite faces, a one dimensional triangulation is a ring of edges and vertices topologically equivalent to a 1-sphere. A zero dimensional triangulation, whose domain is reduced to a single point, is represented by two vertices that is topologically equivalent to a 0-sphere.

Note that the *infinite vertex* has no significant coordinates and that no geometric predicate can be applied on it nor on an infinite face.

A representation based on faces and vertices

Because a triangulation is a set of triangular faces with constant-size complexity, triangulations are not implemented as a layer on top of a planar map. CGAL uses a proper internal representation of triangulations based on faces and vertices rather than on edges. Such a representation saves storage space and results in faster algorithms [BDTY00].

The basic elements of the representation are vertices and faces. Each triangular face gives access to its three incident vertices and to its three adjacent faces. Each vertex gives access to one of its incident faces and through that face to the circular list of its incident faces.

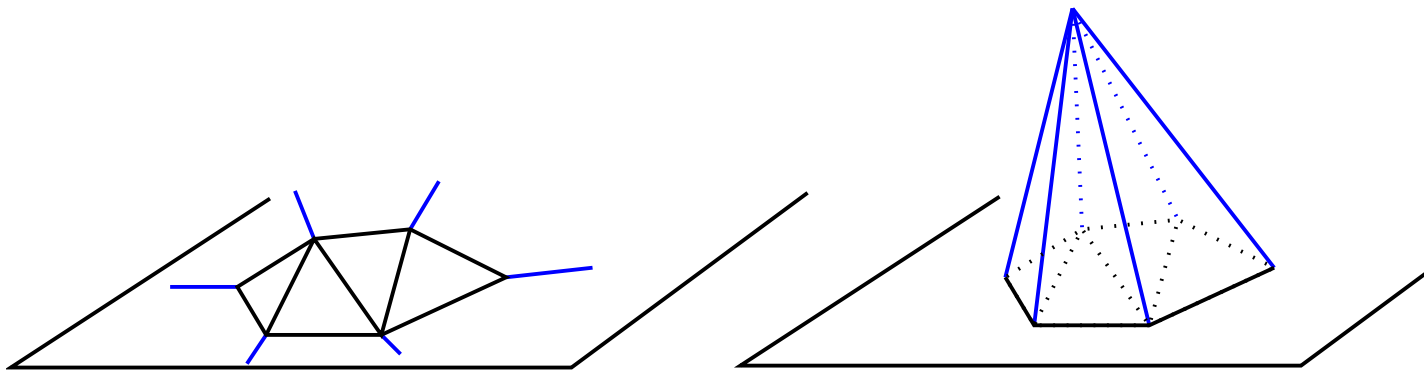

Figure 35.1: Infinite vertex and infinite faces

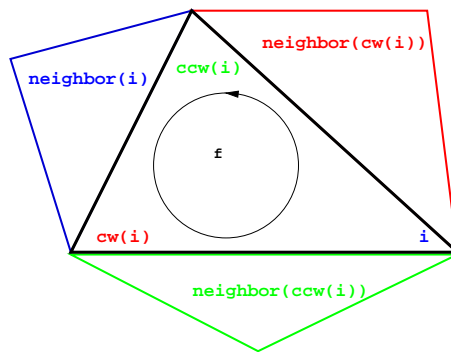

Figure 35.2: Vertices and neighbors.

The three vertices of a face are indexed with 0, 1 and 2 in counterclockwise order. The neighbors of a face are also indexed with 0,1,2 in such a way that the neighbor indexed by i is opposite to the vertex with the same index. See Figure 35.2, the functions $ccw(i)$ and $cw(i)$ shown on this figure compute respectively $i + 1$ and $i - 1$ modulo 3.

The edges are not explicitly represented, they are only implicitly represented through the adjacency relations of two faces. Each edge has two implicit representations: the edge of a face f which is opposed to the vertex indexed i , can be represented as well as an edge of the $neighbor(i)$ of f .

35.3 Software Design

The triangulations classes of CGAL provide high-level geometric functionalities such as location of a point in the triangulation, insertion, removal, or displacement of a point. They are build as a layer on top of a data structure called the triangulation data structure. The triangulation data structure can be thought of as a container for the faces and vertices of the triangulation. This data structure also takes care of all the combinatorial aspects of the triangulation.

This separation between the geometric aspect and the combinatorial part is reflected in the software design by the fact that the triangulation classes have two template parameters:

- the first parameter stands for a **geometric traits** class providing the geometric primitives (points, segments

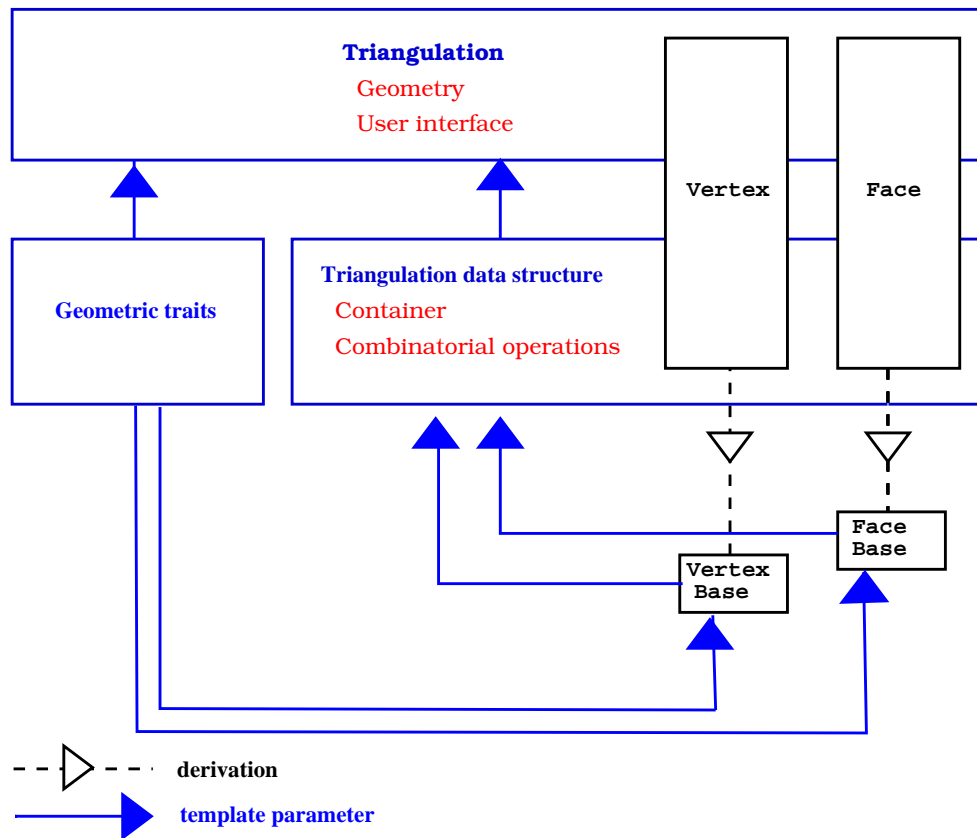

Figure 35.3: The triangulations software design.

and triangles) of the triangulation and the elementary operations (predicate or constructions) on those objects.

- the second parameter stands for a **triangulation data structure** class. The concept of triangulation data structure is described in Section 36.2 of Chapter 36. The triangulation data structure defines the types used to represent the faces and vertices of the triangulation, as well as additional types (handles, iterators and circulators) to access and visit the faces and vertices.

CGAL provides the class *Triangulation_data_structure_2*<Vb,Fb> as a default model of triangulation data structure. The class *Triangulation_data_structure_2*<Vb,Fb> has two template parameters standing for a vertex class and a face class. CGAL defines concepts for these template parameters and provide default models for these concepts. The vertex and base classes are templated by the geometric traits which allows them to have some knowledge of the geometric primitives of the triangulation. Those default vertex and face base classes can be replaced by user customized base classes in order, for example, to deal with additional properties attached to the vertices or faces of a triangulation. See section 35.11 for more details on the way to make use of this flexibility.

The Figure 35.3 summarizes the design of the triangulation package, showing the three layers (base classes, triangulation data structure and triangulation) forming this design.

The top triangulation level, responsible for the geometric embedding of the triangulation comes in different flavors according to the different kind of triangulations: basic, Delaunay, regular, constrained or constrained Delaunay. Each kind of triangulations correspond to a different class. Figure 35.4 summarizes the derivation dependencies of CGAL 2D triangulations classes. Any 2D triangulation class is parametrized by a geometric

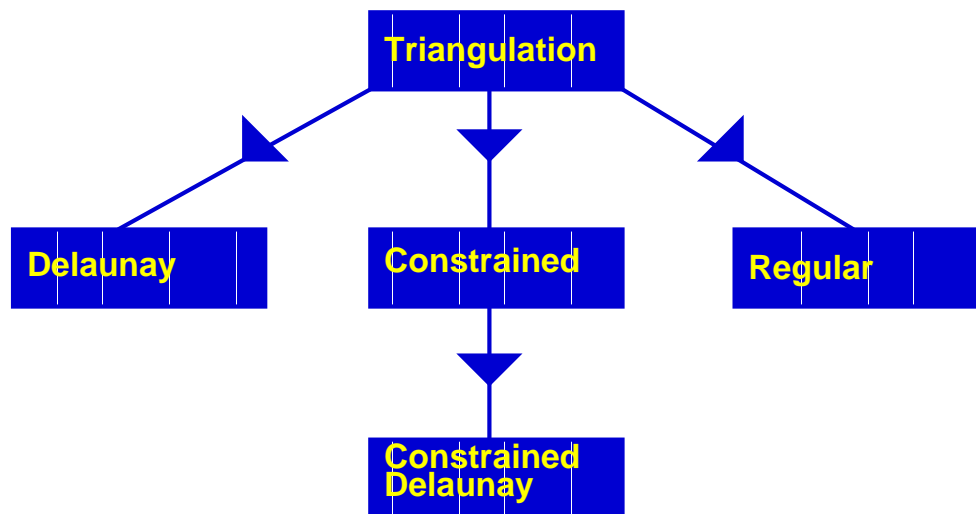

Figure 35.4: The derivation tree of 2D triangulations.

traits and a triangulation data structure. While a unique concept *TriangulationDataStructure_2* describes the triangulation data structure requirements for any triangulation class, the concept of geometric traits actually depends on the triangulation class. In general, the requirements for the vertex and face base classes are described by the basic concepts *TriangulationVertexBase_2* and *TriangulationFaceBase_2*. However, some triangulation classes requires base classes implementing refinements of the basic concepts.

35.4 Basic Triangulations

35.4.1 Description

The class *Triangulation_2*<*Traits*,*Tds*> serves as a base class for the other 2D triangulations classes and implements the user interface to a triangulation.

The vertices and faces of the triangulations are accessed through *handles*, *iterators* and *circulators*. A handle is a model of the concept *Handle* which basically offers the two dereference operators * and -> . A circulator is a type devoted to visit circular sequences. Handles are used whenever the accessed element is not part of a sequence. Iterators and circulators are used to visit all or parts of the triangulation.

The iterators and circulators are all bidirectional and non mutable. The circulators and iterators are convertible to the handles with the same value type, so that when calling a member function, any handle type argument can be replaced by an iterator or a circulator with the same value type.

The triangulation class allows to visit the vertices and neighbors of a face in clockwise or counterclockwise order.

There are circulators to visit the edges or faces incident to a given vertex or the vertices adjacent to it. Another circulator type allows to visit all the faces traversed by a given line. Circulators step through infinite features as well as through finite ones.

The triangulation class offers some iterators to visit all the faces, edges or vertices and also iterators to visit selectively the finite faces, edges or vertices.

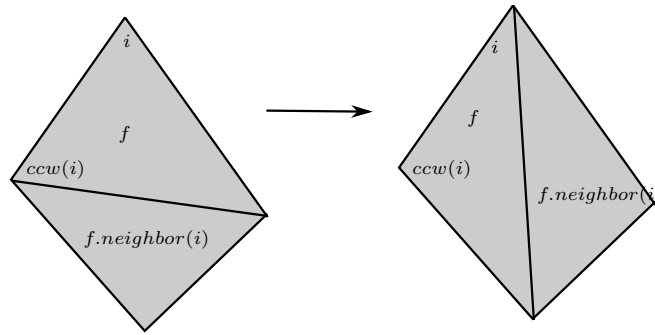

Figure 35.5: Flip.

The triangulation class provides methods to test the infinite character of any feature, and also methods to test the presence in the triangulation of a particular feature (edge or face) given its vertices.

The triangulation class provides a method to locate a given point with respect to a triangulation. In particular, this method reports whether the point coincides with a vertex of the triangulation, lies on an edge, in a face or outside of the convex hull. In case of a degenerate lower dimensional triangulation, the query point may also lie outside the triangulation affine hull.

The triangulation class also provides methods to locate a point with respect to a given finite face of the triangulation or with respect to its circumcircle. The faces of the triangulation and their circumcircles have the counterclockwise orientation.

The triangulation can be modified by several functions: insertion of a point, removal of a vertex, displacement of a vertex, flipping of an edge. The flipping of an edge is possible when the union of the two incident faces forms a convex quadrilateral (see Figure 35.5).

Implementation

Locate is implemented by a line walk. The walk begins at a vertex of the face which is given as an optional argument or at an arbitrary vertex of the triangulation if no optional argument is given. It takes time $O(n)$ in the worst case, but only $O(\sqrt{n})$ on average if the vertices are distributed uniformly at random. The class *Triangulation_hierarchy_2*<Traits,Tds>, described in section 35.10, implements a data structure designed to offer an alternate more efficient point location algorithm.

Insertion of a point is done by locating a face that contains the point, and splitting this face into three new faces. If the point falls outside the convex hull, the triangulation is restored by flips. Apart from the location, insertion takes a time $O(1)$. This bound is only an amortized bound for points located outside the convex hull.

Removal of a vertex is done by removing all adjacent triangles, and re-triangulating the hole. Removal takes a time at most proportional to d^2 , where d is the degree of the removed vertex, which is $O(1)$ for a random vertex.

Displacement of a vertex is done by: first, verifying if the triangulation embedding remains planar after the displacement; if yes the vertex is directly placed at the new location; otherwise, a point is inserted at the new location and the vertex at the obsolete location is removed.

The face, edge, and vertex iterators on finite features are derived from their counterparts visiting all (finite and infinite) features which are themselves derived from the corresponding iterators of the triangulation data structure.

Geometric Traits

The geometric traits of a triangulation is required to provide the geometric objects (points, segments and triangles) building up the triangulation together with the geometric predicates on those objects. The required predicates are:

- comparison of the x or y coordinates of two points.
- the orientation test which computes the order type of three given point.

The concept *TriangulationTraits_2* describes the requirements for the geometric traits class of a triangulation. The CGAL kernel classes are models for this concept. The CGAL library also provides dedicated models of *TriangulationTraits_2* using the kernel geometric objects and predicates. These classes are themselves templated with a CGAL kernel and extract the required types and predicates from the kernel. The traits class *Triangulation_euclidean_traits_2<R>* is designed to deal with ordinary two dimensional points. The class *Triangulation_euclidean_traits_xy_3<R>* is a geometric traits class to build the triangulation of a terrain. Such a triangulation is a two-dimensional triangulation embedded in three dimensional space. The data points are three-dimensional points. The triangulation is build according to the projections of those points on the xy plane and then lifted up to the original three-dimensional data points. This is especially useful to deal with GIS terrains. Instead of really projecting the three-dimensional points and maintaining a mapping between each point and its projection (which costs space and is error prone), the traits class supplies geometric predicates that ignore the z -coordinates of the points. See Section 35.5 for an example. CGAL provides also the geometric traits classes *Triangulation_euclidean_traits_yz_3<R>* and *Triangulation_euclidean_traits_zx_3<R>* to deal with projections on the xz plane and yz -plane, respectively.

35.4.2 Example of a Basic Triangulation

The following program creates a triangulation of 2D points using the default kernel *Exact_predicate_inexact_constructions_kernel* as geometric traits and the default triangulation data structure. The input points are read from a file and inserted in the triangulation. Finally points on the convex hull are written to `cout`.

```
#include <fstream>

#include <CGAL/Exact_predicates_inexact_constructions_kernel.h>
#include <CGAL/Triangulation_2.h>

typedef CGAL::Exact_predicates_inexact_constructions_kernel K;

typedef CGAL::Triangulation_2<K>          Triangulation;
typedef Triangulation::Vertex_circulator  Vertex_circulator;
typedef Triangulation::Point              Point;

int main() {
    std::ifstream in("data/triangulation_prog1.cin");
    std::istream_iterator<Point> begin(in);
    std::istream_iterator<Point> end;

    Triangulation t;
    t.insert(begin, end);

    Vertex_circulator vc = t.incident_vertices(t.infinite_vertex()),
        done(vc);
    if (vc != 0) {
        do { std::cout << vc->point() << std::endl;
        } while(++vc != done);
    }
```

```

    }
    return 0;
}

```

35.5 Delaunay Triangulations

35.5.1 Description

The class *Delaunay_triangulation_2*<*Traits*,*Tds*> is designed to represent the Delaunay triangulation of a set of data points in the plane. A Delaunay triangulation fulfills the following *empty circle property* (also called *Delaunay property*): the circumscribing circle of any facet of the triangulation contains no data point in its interior. For a point set with no subset of four co-circular points the Delaunay triangulation is unique, it is dual to the Voronoi diagram of the set of points.

The class *Delaunay_triangulation_2*<*Traits*,*Tds*> derives from the class *Triangulation_2*<*Traits*,*Tds*>.

The class *Delaunay_triangulation_2*<*Traits*,*Tds*> inherits the types defined by the basic class *Triangulation_2*<*Traits*,*Tds*>. Additional types, provided by the traits class, are defined to represent the dual Voronoi diagram.

The class *Delaunay_triangulation_2*<*Traits*,*Tds*> overwrites the member functions that insert, move, or remove a point in the triangulation to maintain the Delaunay property. It also has a member function (*Vertex_handle nearest_vertex(const Point& p)*) to answer nearest neighbor queries and member functions to construct the elements (vertices and edges) of the dual Voronoi diagram.

Geometric traits

The geometric traits has to be a model of the concept *DelaunayTriangulationTraits_2* which refines the concept *TriangulationTraits_2*. In particular this concept provides the *side_of_oriented_circle* predicate which, given four points *p, q, r, s* decides the position of the point *s* with respect to the circle passing through *p, q* and *r*. The *side_of_oriented_circle* predicate actually defines the Delaunay triangulation. Changing this predicate allows to build variant of Delaunay triangulations for different metrics such that L_1 or L_∞ metric or any metric defined by a convex object. However, the user of an exotic metric must be careful that the constructed triangulation has to be a triangulation of the convex hull which means that convex hull edges have to be Delaunay edges. This is granted for any smooth convex metric (like L_2) and can be ensured for other metrics (like L_∞) by the addition to the point set of well chosen sentinel points.

The CGAL kernel classes and the class *Triangulation_euclidean_traits_2*<*R*> are models of the concept *DelaunayTriangulationTraits_2* for the euclidean metric. The traits class for terrains, *Triangulation_euclidean_traits_xy_3*<*R*>,

Triangulation_euclidean_traits_yz_3<*R*>, and

Triangulation_euclidean_traits_zx_3<*R*>

are also models of *DelaunayTriangulationTraits_2* except that they do not fulfill the requirements for the duality functions and nearest vertex queries.

Implementation

The insertion of a new point in the Delaunay triangulation is performed using first the insertion member function of the basic triangulation and second performing a sequence of flips to restore the Delaunay property. The

number of flips that have to be performed is $O(d)$ if the new vertex has degree d in the updated Delaunay triangulation. For points distributed uniformly at random, each insertion takes time $O(1)$ on average, once the point has been located in the triangulation.

Removal calls the removal in the triangulation and then re-triangulates the hole created in such a way that the Delaunay criterion is satisfied. Removal of a vertex of degree d takes time $O(d^2)$. The degree d is $O(1)$ for a random vertex in the triangulation. When the degree of the removed vertex is small (≤ 7) a special procedure is used that allows to increase global removal time by a factor of 2 for random points [Dev09].

The displacement of a vertex v at a point p to a new location p' , first checks whether the triangulation embedding remains planar or not after moving v to p' . If yes, it moves v to p' and simply performs a sequence of flips to restore the Delaunay property, which is $O(d)$ where d is the degree of the vertex after the displacement. Otherwise, the displacement is done by inserting a vertex at the new location, and removing the obsolete vertex. The complexity is $O(n)$ in the worst case, but only $O(1 + \delta\sqrt{n})$ for evenly distributed vertices in the unit square, where δ is the Euclidean distance between the new and old locations.

After having performed a point location, the nearest neighbor of a point is found in time $O(n)$ in the worst case, but in time $O(1)$ for vertices distributed uniformly at random and any query point.

35.5.2 Example: a Delaunay Terrain

The following code creates a Delaunay triangulation with the usual Euclidean metric for the vertical projection of a terrain model. The points have elevation, that is they are 3D points, but the predicates used to build the Delaunay triangulation are computed using only the x and y coordinates of these points.

```
#include <CGAL/Exact_predicates_inexact_constructions_kernel.h>
#include <CGAL/Triangulation_euclidean_traits_xy_3.h>
#include <CGAL/Delaunay_triangulation_2.h>

#include <fstream>

typedef CGAL::Exact_predicates_inexact_constructions_kernel K;
typedef CGAL::Triangulation_euclidean_traits_xy_3<K> Gt;
typedef CGAL::Delaunay_triangulation_2<Gt> Delaunay;

typedef K::Point_3 Point;

int main()
{
    std::ifstream in("data/terrain.cin");
    std::istream_iterator<Point> begin(in);
    std::istream_iterator<Point> end;

    Delaunay dt;
    dt.insert(begin, end);
    std::cout << dt.number_of_vertices() << std::endl;
    return 0;
}
```

File: examples/Triangulation_2/terrain.cpp

35.5.3 Example: Voronoi Diagram

The following code computes the edges of Voronoi diagram of a set of data points and counts the number of finite edges and the number of rays of this diagram

```
#include <CGAL/Exact_predicates_inexact_constructions_kernel.h>
#include <CGAL/Delaunay_triangulation_2.h>

#include <fstream>

typedef CGAL::Exact_predicates_inexact_constructions_kernel K;

typedef CGAL::Delaunay_triangulation_2<K>   Triangulation;
typedef Triangulation::Edge_iterator          Edge_iterator;
typedef Triangulation::Point                  Point;

int main( )
{
    std::ifstream in("data/voronoi.cin");
    std::istream_iterator<Point> begin(in);
    std::istream_iterator<Point> end;
    Triangulation T;
    T.insert(begin, end);

    int ns = 0;
    int nr = 0;
    Edge_iterator eit = T.edges_begin();
    for ( ; eit != T.edges_end(); ++eit) {
        CGAL::Object o = T.dual(eit);
        if (CGAL::object_cast<K::Segment_2>(&o)) {++ns;}
        else if (CGAL::object_cast<K::Ray_2>(&o)) {++nr;}
    }
    std::cout << "The Voronoi diagram has " << ns << " finite edges "
               << " and " << nr << " rays" << std::endl;
    return 0;
}
```

File: examples/Triangulation_2/voronoi.cpp

35.6 Regular Triangulations

35.6.1 Description

Let $PW = \{(p_i, w_i) | i = 1, \dots, n\}$ be a set of weighted points where each p_i is a point and each w_i is a scalar called the weight of point p_i . Alternatively, each weighted point (p_i, w_i) can be regarded as a sphere (or a circle, depending on the dimensionality of p_i) with center p_i and radius $r_i = \sqrt{w_i}$.

The power diagram of the set PW is a space partition in which each cell corresponds to a sphere (p_i, w_i) of PW and is the locus of points p whose power with respect to (p_i, w_i) is less than its power with respect to any other sphere in PW . In the two-dimensional space, the dual of this diagram is a triangulation whose domain covers

the convex hull of the set $P = \{p_i | i = 1, \dots, n\}$ of center points and whose vertices form a subset of P . Such a triangulation is called a regular triangulation. Three points p_i, p_j and p_k of P form a triangle in the regular triangulation of PW iff there is a point p of the plane with equal powers with respect to (p_i, w_i) , (p_j, w_j) and (p_k, w_k) and such that this power is less than the power of p with respect to any other sphere in PW .

Let us defined the power product of two weighted points (p_i, w_i) and (p_j, w_j) as:

$$\Pi(p_i, w_i, p_j, w_j) = p_i p_j^2 - w_i - w_j.$$

$\Pi(p_i, w_i, p_j, 0)$ is simply the power of point p_j with respect to the sphere (p_i, w_i) , and two weighted points are said to be orthogonal if their power product is null. The power circle of three weighted points (p_i, w_i) , (p_j, w_j) and (p_k, w_k) is defined as the unique circle (π, ω) orthogonal to (p_i, w_i) , (p_j, w_j) and (p_k, w_k) .

The regular triangulation of the sets PW satisfies the following *regular property* (which just reduces to the Delaunay property when all the weights are null): a triangle $p_i p_j p_k$ is a face of the regular triangulation of PW iff the power product of any weighted point (p_l, w_l) of PW with the power circle of (p_i, w_i) , (p_j, w_j) and (p_k, w_k) is positive or null. We call power test of (p_i, w_i) , (p_j, w_j) , (p_k, w_k) , and (p_l, w_l) , the predicates which amount to compute the sign of the power product of (p_l, w_l) with respect to the power circle of (p_i, w_i) , (p_j, w_j) and (p_k, w_k) . This predicate amounts to computing the sign of the following determinant

$$\begin{vmatrix} 1 & x_i & y_i & x_i^2 + y_i^2 - w_i \\ 1 & x_j & y_j & x_j^2 + y_j^2 - w_j \\ 1 & x_k & y_k & x_k^2 + y_k^2 - w_k \\ 1 & x_l & y_l & x_l^2 + y_l^2 - w_l \end{vmatrix}$$

A pair of neighboring faces $p_i p_j p_k$ and $p_i p_j p_l$ is said to be locally regular (with respect to the weights in PW) if the power test of (p_i, w_i) , (p_j, w_j) , (p_k, w_k) , and (p_l, w_l) is positive. A classical result of computational geometry establishes that a triangulation of the convex hull of P such that any pair of neighboring faces is regular with respect to PW , is a regular triangulation of PW .

Alternatively, the regular triangulation of the weighted points set PW can be obtained as the projection on the two dimensional plane of the convex hull of the set of three dimensional points $P' = \{(p_i, p_i^2 - w_i) | i = 1, \dots, n\}$.

The class *Regular_triangulation_2*<Traits, Tds> is designed to maintain the regular triangulation of a set of $2d$ weighted points. It derives from the class *Triangulation_2*<Traits, Tds>. The functions *insert* and *remove* are overwritten to handle weighted points and maintain the regular property. In current version, function *move* is not overwritten and thus does not preserve the regular property. The vertices of the regular triangulation of a set of weighted points PW correspond only to a subset of PW . Some of the input weighted points have no cell in the dual power diagrams and therefore do not correspond to a vertex of the regular triangulation. Such a point is called a hidden point. Because hidden points can reappear later on as vertices when some other point is removed, they have to be stored somewhere. The regular triangulation store those points in special vertices, called hidden vertices. A hidden point can reappear as vertex of the triangulation only when the two dimensional face that hides it is removed from the triangulation. To deal with this feature, each face of a regular triangulation stores a list of hidden vertices. The points in those vertices are reinserted in the triangulation when the face is removed.

Regular triangulation have member functions to construct the vertices and edges of the dual power diagrams.

The geometric traits

The geometric traits of a regular triangulation must provide a weighted point type and a power test on these weighted points. The concept *RegularTriangulationTraits_2*, is a refinement of the concept *TriangulationTraits_2*. CGAL provides the class *Regular_triangulation_euclidean_traits_2*<Rep, Weight> which

is a model for the traits concept *RegularTriangulationTraits_2*. The class *Regular_triangulation_euclidean_traits_2*<Rep,Weight> derives from the class *Triangulation_euclidean_traits_2*<Rep> and uses a *Weighted_point* type derived from the type *Point_2* of *Triangulation_euclidean_traits_2*<Rep>.

Note that, since the type *Weighted_point* is not defined in CGAL kernels, plugging a filtered kernel such as *Exact_predicates_exact_constructions_kernel* in *Regular_triangulation_euclidean_traits_2*<K,Weight> will in fact not provide exact predicates on weighted points. To solve this, there is also another model of the traits concept, *Regular_triangulation_filtered_traits_2*<FK>, which is providing filtered predicates (exact and efficient). The argument *FK* must be a model of the *Kernel* concept, and it is also restricted to be a instance of the *Filtered_kernel* template.

The Vertex type and Face Type of a Regular Triangulation

The base vertex type of a regular triangulation includes a Boolean data member to mark the hidden state of the vertex. Therefore CGAL defines the concept *RegularTriangulationVertexBase_2* which refine the concept *TriangulationVertexBase_2* and provides a default model for this concept.

The base face type of a regular triangulation is required to provide a list of hidden vertices, designed to store the points hidden by the face. It has to be a model of the concept *RegularTriangulationFaceBase_2*. CGAL provides the templated class *Regular_triangulation_face_base_2*<Traits> as a default base class for faces of regular triangulations.

35.6.2 Example: a Regular Triangulation

The following code creates a regular triangulation of a set of weighted points and output the number of vertices and the number of hidden vertices.

```
#include <CGAL/Exact_predicates_inexact_constructions_kernel.h>
#include <CGAL/Regular_triangulation_euclidean_traits_2.h>
#include <CGAL/Regular_triangulation_filtered_traits_2.h>
#include <CGAL/Regular_triangulation_2.h>

#include <fstream>

typedef CGAL::Exact_predicates_inexact_constructions_kernel K;
typedef CGAL::Regular_triangulation_filtered_traits_2<K> Traits;
typedef CGAL::Regular_triangulation_2<Traits> Regular_triangulation;

int main()
{
    Regular_triangulation rt;
    std::ifstream in("data/regular.cin");

    Regular_triangulation::Weighted_point wp;
    int count = 0;
    while(in >> wp){
        count++;
        rt.insert(wp);
    }
    rt.is_valid();
    std::cout << "number of inserted points : " << count << std::endl;
    std::cout << "number of vertices : " ;
```

```

std::cout << rt.number_of_vertices() << std::endl;
std::cout << "number of hidden vertices : " ;
std::cout << rt.number_of_hidden_vertices() << std::endl;
return 0;
}

```

35.7 Constrained Triangulations

A constrained triangulation is a triangulation of a set of points that has to include among its edges a given set of segments joining the points. The corresponding edges are called *constrained edges*.

The endpoints of constrained edges are of course vertices of the triangulation. However the triangulation may include other vertices as well. There are three versions of constrained triangulations.

- In the basic version, the constrained triangulation does not handle intersecting constraints, and the set of input constraints is required to be a set of segments that do not intersect except possibly at their endpoints. Any number of constrained edges are allowed to share the same endpoint. Vertical constrained edges or constrained edges with null length are allowed.
- The two other versions support intersecting input constraints. In those versions, input constraints are allowed to be intersecting, overlapping or partially overlapping segments. The triangulation introduces additional vertices at each point that is the proper intersection points of two constraints. A single constraint intersecting other constraints will then appear as several edges in the triangulation. The two versions dealing with intersecting constraints differ in the way intersecting constraints are dealt with.
 - One of them is designed to be robust when predicates are evaluated exactly but constructions (i. e. intersection computations) are approximate.
 - The other one is designed to be used with exact arithmetic (meaning exact evaluation of predicates and exact computation of intersections.) This last version finds its full efficiency when used in conjunction with a constraint hierarchy data structure (which allows one to avoid the cascading of intersection computations) as provided in the class *Constrained_triangulation_plus_2*. See section 35.9.

A constrained triangulation is represented in the CGAL library as an object of the class *Constrained_triangulation_2<Traits,Tds,Itag>*. The third parameter *Itag* is the intersection tag which serves to choose how intersecting constraints are dealt with. This parameter has to be instantiated by one of the following classes : *CGAL::No_intersection_tag* when input constraints do not intersect

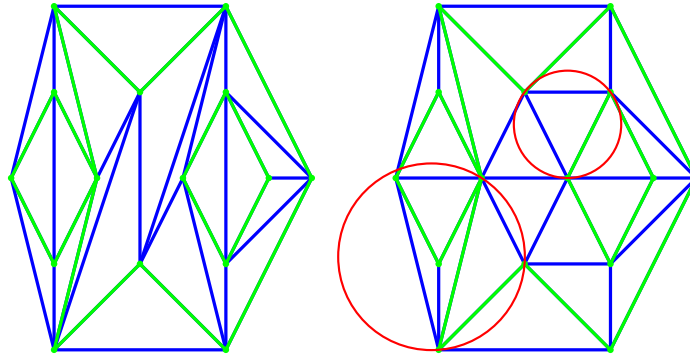

Figure 35.6: Constrained and Constrained Delaunay triangulation: the constraining edges are the green edges, a constrained triangulation is shown on the left, the constrained Delaunay triangulation with two examples of circumcircles is shown on the right.

CGAL::Exact_predicates_tag if the geometric traits provides exact predicates but approximate constructions
CGAL::Exact_intersections_tag when an exact predicates and exact constructions are provided.

The class *Constrained_triangulation_2*<Traits,Tds, Itag> inherits from *Triangulation_2*<Traits,Tds>. It defines an additional type *Constraint* to represent the constraints. A constraint is represented as a pair of points.

A constrained triangulation can be created from a list of constrained edges. The class *Constrained_triangulation_2*<Traits,Tds,Itag> overrides the insertion and removal of a point to take care of the information about constrained edges. The class also allows inline insertion of a new constraint, given by its two endpoints or the removal of a constraint. In current version, function *move* is not overwritten and thus does not take care of the constraints.

The Geometric Traits

The geometric traits of a constraint triangulation has to be a model of the concept *TriangulationTraits_2*. When intersections of input constraints are supported, the geometric traits class has to be a model of the concept *ConstrainedTriangulationTraits_2* which refines the concept *TriangulationTraits_2* providing additional function object types to compute the intersection of two segments.

The Base Face of a Constrained Triangulation

The information about constrained edges is stored in the faces of the triangulation. The base face of a Constrained Triangulation has to be a model for the concept *ConstrainedTriangulationFaceBase_2* which refines the concept *TriangulationFaceBase_2*. The concept *ConstrainedTriangulationFaceBase_2* requires member functions the get and set the constrained status of the edges.

CGAL provides a default base face class for constrained triangulations. This class, named *Constrained_triangulation_face_base_2*<Traits>, derives from the class *Triangulation_face_base_2*<Traits> and adds three Boolean data members to store the status of its edges.

35.8 Constrained Delaunay Triangulations

A constrained Delaunay triangulation is a triangulation with constrained edges which tries to be as much Delaunay as possible. As constrained edges are not necessarily Delaunay edges, the triangles of a constrained Delaunay triangulation do not necessarily fulfill the empty circle property but they fulfill a weaker *constrained empty circle property*. To state this property, it is convenient to think of constrained edges as blocking the view. Then, a triangulation is constrained Delaunay iff the circumscribing circle of any facet encloses no vertex visible from the interior of the facet. As in the case of constrained triangulations, three different versions of Delaunay constrained triangulations are provided. The first version handle set of constraints which do not intersect except possibly at the endpoints. The two other versions handle intersecting input constraints. One of them is designed to be designed to be robust when used in conjunction with a geometric traits providing exact predicates and approximate constructions (such as a `CGAL::Filtered_Kernel` or any kernel providing filtered exact predicates). The third version is designed to be used with an exact arithmetic number type.

The CGAL class `Constrained_Delaunay_triangulation_2<Traits,Tds,Itag>` is designed to represent constrained Delaunay triangulations.

As in the case of constraints triangulation, the third parameter `Itag` is the intersection tag and serves to choose how intersecting constraints are dealt with. It can be instantiated with one of the following class : `CGAL::No_intersection_tag`, `CGAL::Exact_predicates_tag`, `CGAL::Exact_intersections_tag` (see Section 35.7).

A constrained Delaunay triangulation is not a Delaunay triangulation but it is a constrained triangulation. Therefore the class `Constrained_Delaunay_triangulation_2<Traits,Tds,Itag>` derives from the class `Constrained_triangulation_2<Traits,Tds,Itag>`.

The constrained Delaunay triangulation has member functions to override the insertion and removal of a point or of a constraint. Each of those member function takes care to restore the constrained empty circle property.

The Geometric Traits

The geometric traits of a constrained Delaunay triangulation is required to provide the *side_of_oriented_circle* predicate as the geometric traits of a Delaunay triangulation and has to a model of the concept `DelaunayTriangulationTraits_2`. When intersecting input constraints are supported the geometric traits is further required to provide function objects to compute constraints intersections. Then the geometric traits has to be at the same time a model of the concept `ConstrainedTriangulationTraits_2`.

The face base class

Information about the status (constrained or not) of the edges of the triangulation has to be stored in the face class and the base face class of a constrained Delaunay triangulation has to be a model of `ConstrainedTriangulationFaceBase_2`.

35.8.1 Example: a Constrained Delaunay Triangulation

The following code inserts a set of intersecting constraint segments into a triangulation and counts the number of constrained edges of the resulting triangulation.

```
#include <CGAL/Exact_predicates_inexact_constructions_kernel.h>
#include <CGAL/Constrained_Delaunay_triangulation_2.h>
```

```

#include <cassert>
#include <iostream>

typedef CGAL::Exact_predicates_inexact_constructions_kernel K;

typedef CGAL::Triangulation_vertex_base_2<K> Vb;
typedef CGAL::Constrained_triangulation_face_base_2<K> Fb;
typedef CGAL::Triangulation_data_structure_2<Vb,Fb> TDS;
typedef CGAL::Exact_predicates_tag Itag;
typedef CGAL::Constrained_Delaunay_triangulation_2<K, TDS, Itag> CDT;
typedef CDT::Point Point;

int
main( )
{
    CDT cdt;
    std::cout << "Inserting a grid of 5x5 constraints " << std::endl;
    for (int i = 1; i < 6; ++i)
        cdt.insert_constraint( Point(0,i), Point(6,i));
    for (int j = 1; j < 6; ++j)
        cdt.insert_constraint( Point(j,0), Point(j,6));

    assert(cdt.is_valid());
    int count = 0;
    for (CDT::Finite_edges_iterator eit = cdt.finite_edges_begin();
        eit != cdt.finite_edges_end();
        ++eit)
        if (cdt.is_constrained(*eit)) ++count;
    std::cout << "The number of resulting constrained edges is ";
    std::cout << count << std::endl;
    return 0;
}

```

File: examples/Triangulation_2/constrained.cpp

35.9 Constrained Triangulations Plus

The class *Constrained_triangulation_plus_2<Tr>* provides a constrained triangulation with an additional data structure called the constraint hierarchy that keeps track of the input constraints and of their refinement in the triangulation. The class *Constrained_triangulation_plus_2<Tr>* inherits from its template parameter *Tr*, which has to be instantiated by a constrained or constrained Delaunay triangulation. According to its intersection tag, the base class will support intersecting input constraints or not. When intersections of input constraints are supported, the base class constructs a triangulation of the arrangement of the constraints, introducing new vertices at each proper intersection points and refining the input constraints into sub-constraints which appear as edges (more precisely as constrained edges) of the triangulation. The data structure maintains for each input constraint the sequence of intersection vertices added on this constraint. The constraint hierarchy also allows the user to retrieve the set of constrained edges of the triangulation, and for each constrained edge, the set of input constraints that overlap it.

The class *Constrained_triangulation_plus_2<Tr>* is especially useful when the base constrained triangulation

class handles intersections of constraints and uses an exact number type, i.e. when its intersection tag is *CGAL::Exact_intersections_tag*. Indeed in this case, the *Constrained_triangulation_plus_2<Tr>* is specially designed to avoid cascading in the computations of intersection points.

35.9.1 Example: Building a Triangulated Arrangement of Segments

The following code inserts a set of intersecting constraint segments into a triangulation and counts the number of constrained edges of the resulting triangulation.

```
#include <CGAL/Exact_predicates_exact_constructions_kernel.h>
#include <CGAL/intersections.h>
#include <CGAL/Constrained_Delaunay_triangulation_2.h>
#include <CGAL/Constrained_triangulation_plus_2.h>

#include <cassert>
#include <iostream>

typedef CGAL::Exact_predicates_exact_constructions_kernel K;

typedef CGAL::Triangulation_vertex_base_2<K>          Vb;
typedef CGAL::Constrained_triangulation_face_base_2<K> Fb;
typedef CGAL::Triangulation_data_structure_2<Vb,Fb>   TDS;
typedef CGAL::Exact_intersections_tag                 Itag;
typedef CGAL::Constrained_Delaunay_triangulation_2<K,TDS,Itag> CDT;
typedef CGAL::Constrained_triangulation_plus_2<CDT>    CDTplus;
typedef CDTplus::Point                                 Point;

int
main( )
{
    CDTplus cdt;
    std::cout << "Inserting a grid 5 x 5 of constraints " << std::endl;
    for (int i = 1; i < 6; ++i)
        cdt.insert_constraint( Point(0,i), Point(6,i));
    for (int j = 1; j < 6; ++j)
        cdt.insert_constraint( Point(j,0), Point(j,6));

    assert(cdt.is_valid());
    int count = 0;
    for (CDTplus::Subconstraint_iterator scit = cdt.subconstraints_begin();
         scit != cdt.subconstraints_end();
         ++scit) ++count;
    std::cout << "The number of resulting constrained edges is "
              << count << std::endl;
    return 0;
}
```

File: examples/Triangulation_2/constrained_plus.cpp

35.10 The Triangulation Hierarchy

The class *Triangulation_hierarchy_2*<*Tr*> implements a triangulation augmented with a data structure to answer efficiently point location queries. The data structure is a hierarchy of triangulations. The triangulation at the lowest level is the original triangulation where operations and point location are to be performed. Then at each succeeding level, the data structure stores a triangulation of a small random sample of the vertices of the triangulation at the preceding level. Point location is done through a top down nearest neighbor query. The nearest neighbor query is first performed naively in the top level triangulation. Then, at each following level, the nearest neighbor at that level is found through a linear walk performed from the nearest neighbor found at the preceding level. Because the number of vertices in each triangulation is only a small fraction of the number of vertices of the preceding triangulation, the data structure remains small and achieves fast point location queries on real data. As proved in [Dev98], this structure has an optimal behavior when it is built for Delaunay triangulations. However it can be used as well for other triangulations and the class *Triangulation_hierarchy_2*<*Tr*> is templated by a parameter which is to be instantiated by one of the CGAL triangulation classes.

The class *Triangulation_hierarchy_2*<*Tr*> inherits from the triangulation type passed as template parameter *Tr*. The *insert*, *move*, and *remove* member functions are overwritten to update the data structure at each operation. The locate queries are also overwritten to take advantage of the data structure for a fast processing.

The Vertex of a Triangulation Hierarchy

The base vertex class of a triangulation hierarchy has to be a model of the concept *TriangulationHierarchyVertexBase_2* which extends the concept *TriangulationVertexBase_2*. This extension adds access and setting member functions for two pointers to the corresponding vertices in the triangulations of the next and preceding levels.

CGAL provides the class *Triangulation_hierarchy_vertex_base_2*<*Vb*> which is a model for the concept *TriangulationHierarchyVertexBase_2*. This class is templated by a parameter *Vb* which is to be instantiated by a model of the concept *TriangulationVertexBase_2*. The class *Triangulation_hierarchy_vertex_base_2*<*Vb*> inherits from its template parameter *Vb*. This design allows to use for *Vb* either the default vertex class or a user customized vertex class with additional functionalities.

35.10.1 Examples For the Use of a Triangulation Hierarchy

The following program is example for the standard use of a triangulation hierarchy to enhance the efficiency of a Delaunay triangulation. The program outputs the number of vertices at the different levels of the hierarchy.

```
#include <CGAL/Exact_predicates_inexact_constructions_kernel.h>
#include <CGAL/Delaunay_triangulation_2.h>
#include <CGAL/Triangulation_hierarchy_2.h>
#include <CGAL/point_generators_2.h>
#include <CGAL/algorithm.h>
#include <cassert>

typedef CGAL::Exact_predicates_inexact_constructions_kernel K;

typedef CGAL::Triangulation_vertex_base_2<K> Vbb;
typedef CGAL::Triangulation_hierarchy_vertex_base_2<Vbb> Vb;
typedef CGAL::Triangulation_face_base_2<K> Fb;
typedef CGAL::Triangulation_data_structure_2<Vb, Fb> Tds;
typedef CGAL::Delaunay_triangulation_2<K, Tds> Dt;
```

```

typedef CGAL::Triangulation_hierarchy_2<Dt>           Triangulation;
typedef Triangulation::Point                          Point;
typedef CGAL::Creator_uniform_2<double,Point>         Creator;

int main( )
{
    std::cout << "insertion of 1000 random points" << std::endl;
    Triangulation t;
    CGAL::Random_points_in_square_2<Point,Creator> g(1.);
    CGAL::copy_n( g, 1000, std::back_inserter(t));

    //verbose mode of is_valid ; shows the number of vertices at each
    level
    std::cout << "The number of vertices at successive levels" <<
        std::endl;
    assert(t.is_valid(true));

    return 0;
}

```

File: examples/Triangulation_2/hierarchy.cpp

The following program shows how to use a triangulation hierarchy in conjunction with a constrained triangulation plus.

```

#include <CGAL/Exact_predicates_inexact_constructions_kernel.h>
#include <CGAL/Constrained_Delaunay_triangulation_2.h>
#include <CGAL/Triangulation_hierarchy_2.h>
#include <CGAL/Constrained_triangulation_plus_2.h>

#include <cassert>
#include <iostream>

typedef CGAL::Exact_predicates_inexact_constructions_kernel K;

typedef CGAL::Triangulation_vertex_base_2<K>           Vbb;
typedef CGAL::Triangulation_hierarchy_vertex_base_2<Vbb> Vb;
typedef CGAL::Constrained_triangulation_face_base_2<K> Fb;
typedef CGAL::Triangulation_data_structure_2<Vb,Fb>    TDS;
typedef CGAL::Exact_predicates_tag                     Itag;
typedef CGAL::Constrained_Delaunay_triangulation_2<K,TDS,Itag> CDT;
typedef CGAL::Triangulation_hierarchy_2<CDT>           CDTH;
typedef CGAL::Constrained_triangulation_plus_2<CDTH>   Triangulation;

typedef Triangulation::Point                          Point;

int
main( )
{
    Triangulation cdt;
    std::cout << "Inserting a grid 5 x 5 of constraints " << std::endl;
    for (int i = 1; i < 6; ++i)
        cdt.insert_constraint( Point(0,i), Point(6,i));
}

```

```

    for (int j = 1; j < 6; ++j)
        cdt.insert_constraint( Point(j,0), Point(j,6));

    int count = 0;
    for (Triangulation::Subconstraint_iterator scit =
        cdt.subconstraints_begin();
        scit != cdt.subconstraints_end();
        ++scit) ++count;
    std::cout << "The number of resulting constrained edges is ";
    std::cout << count << std::endl;

    //verbose mode of is_valid ; shows the number of vertices at each
    level
    std::cout << "The number of vertices at successive levels" <<
        std::endl;
    assert(cdt.is_valid(true));

    return 0;
}

```

File: examples/Triangulation_2/constrained_hierarchy_plus.cpp

35.11 Flexibility: Using Customized Vertices and Faces

To be able to adapt to various needs, a highly flexible design has been selected for 2D triangulations. We have already seen that the triangulation classes have two parameters: a geometric traits class and a triangulation data structure class which the user can instantiate with his own customized classes.

The most useful flexibility however comes from the fact that the triangulation data structure itself has two template parameters to be instantiated by classes for the vertices and faces of the triangulation. Using his own customized classes to instantiate these parameters, the user can easily build up a triangulation with additional information or functionality in the vertices and faces.

A cyclic dependency

To insure flexibility, the triangulation data structure is templated by the vertex and face base classes. Also since incidence and adjacency relations are stored in vertices and faces, the base classes have to know the types of handles on vertices and faces provided by the triangulation data structure. Thus the vertex and base classes have to be themselves parameterized by the triangulation data structure, and there is a cyclic dependency on template parameter.

Previously, this cyclic dependency was avoided by using only *void** pointers in the interface of base classes. These *void** were converted to appropriate types at the triangulation data structure levels. This solution had some drawbacks : mainly the user could not add in the vertices or faces of the triangulation a functionality related to types defined by the triangulation data structure, for instance a handle to a vertex, and he was lead to use himself *void** pointers). The new solution to resolve the template dependency is based on a rebind mechanism similar to the mechanism used in the standard allocator class `std::allocator`. The rebind mechanism is described in Section 36.3 of Chapter 36. For now, we will just notice that the design requires the existence

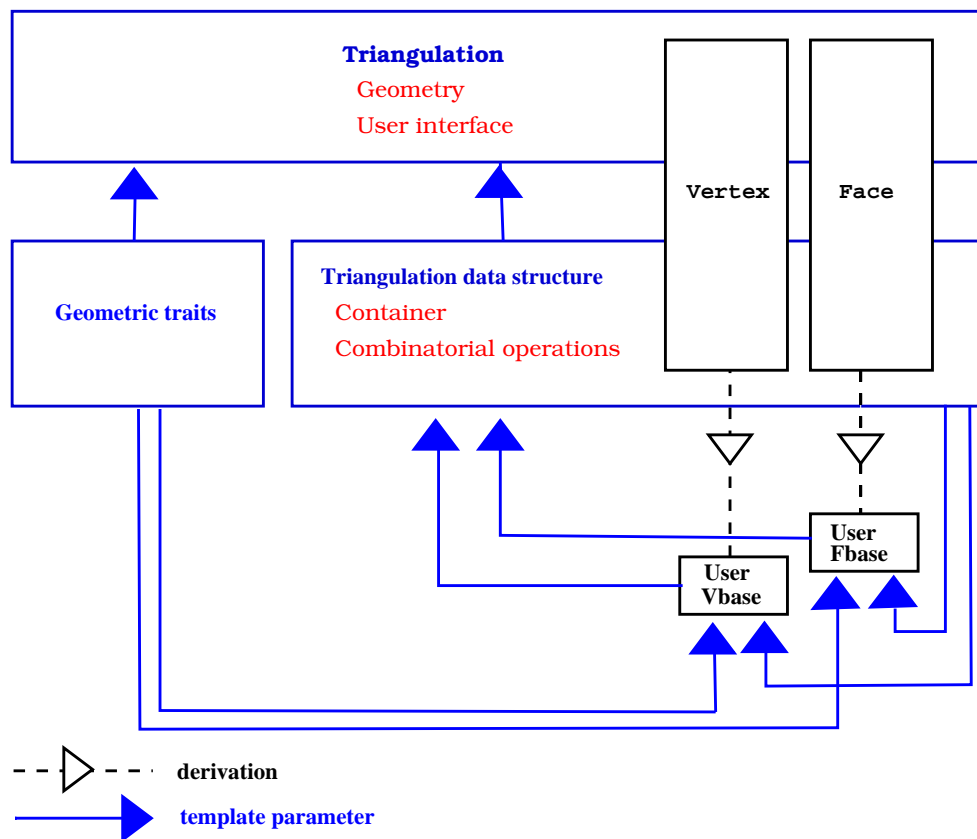

Figure 35.7: The cyclic dependency in triangulations software design.

in the vertex and face base classes of a nested template class *Rebind_TDS* defining a type *Other* used by the rebinding mechanism.

The two following examples show how the user can put in use the flexibility offered by the base classes parameters.

Adding colors

The first example corresponds to a case where the user wishes to add in the vertices or faces of the triangulation an additional information that does not depend on types provided by the triangulation data structure. In that case, predefined classes *Triangulation_vertex_base_with_info_2*<Info,Traits,Vb> or *Triangulation_face_base_with_info_2*<Info,Traits,Vb> can be used. Those classes have a template parameter *Info* devoted to handle additional information. The following examples shows how to add a *CGAL::Color* in the triangulation faces.

```
#include <CGAL/Exact_predicates_inexact_constructions_kernel.h>
#include <CGAL/IO/Color.h>
#include <CGAL/Triangulation_2.h>
#include <CGAL/Triangulation_face_base_with_info_2.h>

typedef CGAL::Exact_predicates_inexact_constructions_kernel K;

typedef CGAL::Triangulation_vertex_base_2<K> Vb;
typedef CGAL::Triangulation_face_base_with_info_2<CGAL::Color,K> Fb;
typedef CGAL::Triangulation_data_structure_2<Vb,Fb> Tds;
typedef CGAL::Triangulation_2<K,Tds> Triangulation;

typedef Triangulation::Face_handle Face_handle;
typedef Triangulation::Finite_faces_iterator Finite_faces_iterator;
typedef Triangulation::Point Point;

int main() {
    Triangulation t;
    t.insert(Point(0,1));
    t.insert(Point(0,0));
    t.insert(Point(2,0));
    t.insert(Point(2,2));

    Finite_faces_iterator fc = t.finite_faces_begin();
    for( ; fc != t.finite_faces_end(); ++fc) fc->info() = CGAL::BLUE;

    Point p(0.5,0.5);
    Face_handle fh = t.locate(p);
    fh->info() = CGAL::RED;

    return 0;
}
```

File: examples/Triangulation_2/colored_face.cpp

Adding handles

The second example shows how the user can still derive and plug in his own vertex or face class when he would like to have additional functionalities depending on types provided by the triangulation data structure.

```
#include <CGAL/Exact_predicates_inexact_constructions_kernel.h>
#include <CGAL/Triangulation_2.h>
#include <cassert>

/* A vertex class with an additionnal handle */
template < class Gt, class Vb = CGAL::Triangulation_vertex_base_2<Gt> >
class My_vertex_base
: public Vb
{
    typedef Vb Base;
public:
    typedef typename Vb::Vertex_handle Vertex_handle;
    typedef typename Vb::Face_handle Face_handle;
    typedef typename Vb::Point Point;

    template < typename TDS2 >
    struct Rebind_TDS {
        typedef typename Vb::template Rebind_TDS<TDS2>::Other Vb2;
        typedef My_vertex_base<Gt, Vb2> Other;
    };

private:
    Vertex_handle va_;

public:
    My_vertex_base() : Base() {}
    My_vertex_base(const Point & p) : Base(p) {}
    My_vertex_base(const Point & p, Face_handle f) : Base(f,p) {}
    My_vertex_base(Face_handle f) : Base(f) {}

    void set_associated_vertex(Vertex_handle va) { va_ = va; }
    Vertex_handle get_associated_vertex() {return va_ ; }
};

typedef CGAL::Exact_predicates_inexact_constructions_kernel K;

typedef My_vertex_base<K> Vb;
typedef CGAL::Triangulation_data_structure_2<Vb> Tds;
typedef CGAL::Triangulation_2<K,Tds> Triangulation;

typedef Triangulation::Vertex_handle Vertex_handle;
typedef Triangulation::Finite_faces_iterator Finite_faces_iterator;
typedef Triangulation::Point Point;

int main() {
    Triangulation t;
    Vertex_handle v0 = t.insert(Point(0,1));
    Vertex_handle v1 = t.insert(Point(0,0));
    Vertex_handle v2 = t.insert(Point(2,0));
```

```
Vertex_handle v3 = t.insert(Point(2,2));

// associate vertices as you like
v0->set_associated_vertex(v1);
v1->set_associated_vertex(v2);
v2->set_associated_vertex(v3);
v3->set_associated_vertex(v0);
assert( v0->get_associated_vertex() == v1);

return 0;
}
```

File: examples/Triangulation_2/adding_handles.cpp

35.12 Design and Implementation History

The code of this package is the result of a long development process. Here follows a tentative list of people who added their stone to this package : Jean-Daniel Boissonnat, Hervé Brönnimann, Olivier Devillers, Andreas Fabri, Frédéric Fichel, Julia Flötotto, Monique Teillaud and Mariette Yvinec.

2D Triangulations

Reference Manual

Mariette Yvinec

A triangulation is a 2-dimensional simplicial complex which is pure connected and without singularities. Thus a triangulation can be viewed as a collection of triangular faces, such that two faces either have an empty intersection or share an edge or a vertex.

The basic elements of the representation are vertices and faces. Each triangular face gives access to its three incident vertices and to its three adjacent faces. Each vertex gives access to one of its incident faces and through that face to the circular list of its incident faces. The edges are not explicitly represented, they are only represented through the adjacency relations of two faces.

The triangulation classes of CGAL depend on two template parameters. The first template parameter stands for a geometric traits class which is assumed to provide the geometric objects (points, segments and triangles) forming the triangulation and the geometric predicates on those objects. The second template parameter stands for a model of triangulation data structure acting as a container for faces and vertices while taking care of the combinatorial aspects of the triangulation. The concepts and models relative to the triangulation data structure are described in Chapter [36.3.4](#).

ConstrainedDelaunayTriangulationTraits_2

Definition

The concept `ConstrainedDelaunayTriangulationTraits_2` defines the requirements for the geometric traits class of a constrained Delaunay triangulation that supports intersections of input constraints. This is the case when the template parameter *Itag* of (*Constrained_Delaunay_triangulation_2*<*Traits*,*Tds*,*Itag*>) is instantiated by one of the tag classes *Exact_intersections_tag* or *Exact_predicates_tag*. The concept `ConstrainedDelaunayTriangulationTraits_2` refines both the concept *DelaunayTriangulationTraits_2* and the concept *ConstrainedTriangulationTraits_2*.

ConstrainedTriangulationFaceBase_2

Definition

In a constrained triangulation, the information about constrained edges is stored in the faces of the triangulation. The base face of a constrained triangulation has to be a model of the concept `ConstrainedTriangulationFaceBase_2` which refines the concept `TriangulationFaceBase_2` providing functionalities to deal with constraints.

Refines

`TriangulationFaceBase_2`

Types

Defines the same types as the `TriangulationFaceBase_2` concept

Access Functions

`bool f.is_constrained(int i)`

returns true if the edge between f and its neighbor $f.\text{neighbor}(i)$ is constrained.
Precondition: $0 \leq i \leq 2$.

— advanced —

Modifiers

`void f.set_constraint(int i, bool b)`

sets the edge between f and its neighbor $f.\text{neighbor}(i)$ as a constrained or unconstrained edge according to b .

`void f.set_constraints(bool c0, bool c1, bool c2)`

sets the status (constrained or unconstrained) of the three edges of f .

`void f.reorient()`

Changes the orientation of f by exchanging $\text{vertex}(0)$ with $\text{vertex}(1)$ and $\text{neighbor}(0)$ with $\text{neighbor}(1)$ and the corresponding constrained status.

`void f.ccw_permute()`

performs a counterclockwise permutation of the vertices, neighbors and constrained status of f .

`void f.cw_permute()`

performs a clockwise permutation of the vertices and neighbors and constrained status of f .

Miscellaneous

bool *f.is_valid()* tests the validity of face *f* as a face of a plain triangulation and additionally checks if the edges of *f* are consistently marked as constrained or unconstrained edges in face *f* and its neighbors.

ConstrainedTriangulationTraits_2

Definition

The concept `ConstrainedTriangulationTraits_2` defines the requirements for the geometric traits class of a constrained triangulation (*Constrained_Triangulation_2*<*Traits*,*Tds*,*Itag*>) that supports intersections of input constraints (i. e. when the template parameter *Itag* is instantiated by one of the tag classes *Exact_intersections_tag* or *Exact_predicates_tag*). This concept refines the concept *TriangulationTraits_2*, adding requirements for function objects to compute the intersection points of two constraints. When *Exact_predicates_tag* is used, the traits class is also required to provide additional types to compute the squared distance between a point and a line

Refines

TriangulationTraits_2

Types

ConstrainedTriangulationTraits_2:: Intersect_2

A function object whose operator() computes the intersection of two segments :

Object_2 operator()(Segment_2 s1, Segment_2 s2); Returns the intersection of *s1* and *s2*.

When the constrained triangulation is instantiated with the intersection tag *Exact_predicates_tag*, the used algorithm needs to be able to compare some distances between points and lines and the following types are further required.

ConstrainedTriangulationTraits_2:: RT

A number type supporting the comparison operator <.

ConstrainedTriangulationTraits_2:: Line_2

The line type.

ConstrainedTriangulationTraits_2:: Construct_line_2

A function object whose operator() constructs a line from two points :

Line_2 operator()(Point_2 p1, Point_2 p2);

ConstrainedTriangulationTraits_2:: Compute_squared_distance_2

A function object with an operator() designed to compute the squared distance between a line and a point :

RT operator()(Line_2 l, Point_2 p); Return the squared distance between *p* and *l*.

Access to constructor object

Intersect_2

traits.intersect_2_object()

Construct_line_2 *traits.construct_line_2_object()*

required when the intersection tag is *Exact_predicates_tag*.

Compute_squared_distance_2

traits.compute_squared_distance_2_object()

required when the intersection tag is *Exact_predicates_tag*.

ConstrainedDelaunayTriangulationTraits_2

CGAL:Constrained_Triangulation_2<Traits,Tds,Itag>

CGAL::Constrained_Delaunay_triangulation_2<Traits,Tds,Itag>

Definition

A constrained Delaunay triangulation is a triangulation with constrained edges which tries to be as much Delaunay as possible. Constrained edges are not necessarily Delaunay edges, therefore a constrained Delaunay triangulation is not a Delaunay triangulation. A constrained Delaunay is a triangulation whose faces do not necessarily fulfill the empty circle property but fulfill a weaker property called the *constrained empty circle*. To state this property, it is convenient to think of constrained edges as blocking the view. Then, a triangulation is constrained Delaunay if the circumscribing circle of any of its triangular faces includes in its interior no vertex that is visible from the interior of the triangle. The class *Constrained_Delaunay_triangulation_2<Traits,Tds,Itag>* is designed to represent constrained Delaunay triangulations.

As in the case of constrained triangulations, three different versions of Delaunay constrained triangulations are offered depending on whether the user wishes to handle intersecting input constraints or not. The desired version can be selected through the instantiation of the third template parameter *Itag* which can be one of the following :

CGAL::No_intersection_tag if intersections of input constraints are disallowed,

CGAL::Exact_predicates_tag allows intersections between input constraints and is to be used when the traits class provides exact predicates but approximate constructions of the intersection points. *CGAL::Exact_intersections_tag* allows intersections between input constraints and is to be used in conjunction with an exact arithmetic type.

The template parameters *Tds* has to be instantiate with a model of *TriangulationDataStructure_2*. The geometric traits of a constrained Delaunay triangulation is required to provide the *side_of_oriented_circle* test as the geometric traits of a Delaunay triangulation and the *Traits* parameter has to be instantiated with a model *DelaunayTriangulationTraits_2*. When intersection of input constraints are supported, the geometric traits class is required to provide additional function object types to compute the intersection of two segments. and has then to be also a model of the concept *ConstrainedTriangulationTraits_2*.

A constrained Delaunay triangulation is not a Delaunay triangulation but it is a constrained triangulation. Therefore the class *Constrained_Delaunay_triangulation_2<Traits,Tds,Itag>* derives from the class *Constrained_triangulation_2<Traits,Tds>*. Also, information about the status (constrained or not) of the edges of the triangulation is stored in the faces. Thus the nested *Face* type of a constrained triangulation offers additional functionalities to deal with this information. These additional functionalities induce additional requirements on the base face class plugged into the triangulation data structure of a constrained Delaunay triangulation. The base face of a constrained Delaunay triangulation has to be a model of the concept *ConstrainedTriangulationFaceBase_2*.

CGAL provides a default for the template parameters. If *Gt* is the geometric traits parameter, the default for *ConstrainedTriangulationFaceBase_2* is the class *CGAL::Constrained_triangulation_face_base_2<Gt>* and the default for the triangulation data structure parameter is the class *CGAL::Triangulation_data_structure_2<CGAL::Triangulation_vertex_base_2<Gt>, CGAL::Constrained_triangulation_face_base_2<Gt> >*. The default intersection tag is *CGAL::No_intersection_tag*.

```
#include <CGAL/Constrained_Delaunay_triangulation_2.h>
```

Inherits From

Constrained_triangulation_2<Traits,Tds,Itag>

Types

All types used in this class are inherited from the base class *Constrained_triangulation_2*<*Traits*,*Tds*,*Itag*>.

Creation

Constrained_Delaunay_triangulation_2<*Traits*,*Tds*,*Itag*> *cdt*(*Traits* *t* = *Traits*());

Introduces an empty constrained Delaunay triangulation *cdt*.

Constrained_Delaunay_triangulation_2<*Traits*,*Tds*,*Itag*> *cdt*(*Constrained_Delaunay_triangulation_2* *cdt1*);

Copy constructor, all faces and vertices are duplicated and the constrained status of edges is copied.

```
template<class InputIterator>
Constrained_Delaunay_triangulation_2<Traits,Tds,Itag> cdt( InputIterator first,
                                                         InputIterator last,
                                                         Traits t=Traits() )
```

A templated constructor which introduces and builds a constrained triangulation with constrained edges in the range *[first, last)*.

Precondition: The *value_type* of *first* and *last* is *Constraint*.

Insertion and Removal

The following member functions overwrite the corresponding members of the base class to include a step restoring the Delaunay constrained property after modification of the triangulation.

Vertex_handle *cdt.insert*(*Point* *p*, *Face_handle* *f* = *Face_handle*())

Inserts point *p* in the triangulation. If present *f* is used as an hint for the location of *p*.

Vertex_handle *cdt.insert*(*Point* *p*, *Locate_type*& *lt*, *Face_handle* *loc*, *int* *li*)

Same as above except that the location of the point *p* to be inserted is assumed to be given by *(lt,loc,i)*.

Vertex_handle *cdt.push_back*(*Point* *p*)

Equivalent to *insert(p)*.

```
template < class InputIterator >
std::ptrdiff_t                    cdt.insert( InputIterator first, InputIterator last )
```

Inserts the points in the range *[first, last)*. Returns the number of inserted points.

Precondition: The *value_type* of *first* and *last* is *Point*.

<i>void</i>	<i>cdt.insert_constraint(Point a, Point b)</i>	Inserts segment <i>ab</i> as a constrained edge in the triangulation.
<i>void</i>	<i>cdt.push_back(Constraint c)</i>	Inserts constraints <i>c</i> as above.
<i>void</i>	<i>cdt.insert_constraint(Vertex_handle va, Vertex_handle vb)</i>	Inserts the line segment whose endpoints are the vertices <i>va</i> and <i>vb</i> as a constrained edge <i>e</i> in the triangulation.
<i>void</i>	<i>cdt.remove(Vertex_handle & v)</i>	Removes vertex <i>v</i> . <i>Precondition:</i> Vertex <i>v</i> is not incident to a constrained edge.
<i>void</i>	<i>cdt.remove_incident_constraints(Vertex_handle v)</i>	Make the edges incident to vertex <i>v</i> unconstrained edges.
<i>void</i>	<i>cdt.remove_constraint(Face_handle f, int i)</i>	Edge <i>(f,i)</i> is no longer constrained.

Queries

The following template member functions query the set of faces in conflict with a point *p*. The notion of conflict refers here to a constrained Delaunay setting which means the following. Constrained edges are considered as visibility obstacles and a point *p* is considered to be in conflict with a face *f* iff it is visible from the interior of *f* and included in the circumcircle of *f*.

```
template <class OutputItFaces, class OutputItBoundaryEdges>
std::pair<OutputItFaces,OutputItBoundaryEdges>
```

```
    cdt.get_conflicts_and_boundary( Point p,
                                   OutputItFaces fit,
                                   OutputItBoundaryEdges eit,
                                   Face_handle start)
```

OutItFaces is an output iterator with *Face_handle* as value type. *OutItBoundaryEdges* stands for an output iterator with *Edge* as value type. This members function outputs in the container pointed to by *fit* the faces which are in conflict with point *p*. It outputs in the container pointed to by *eit* the boundary of the zone in conflict with *p*. The boundary edges of the conflict zone are output in counterclockwise order and each edge is described through its incident face which is not in conflict with *p*. The function returns in a `std::pair` the resulting output iterators.

Precondition: `dimension()==2`

```
template <class OutputItFaces>
```

```
OutputItFaces      cdt.get_conflicts( Point p, OutputItFaces fit, Face_handle start)
```

Same as above except that only the faces in conflict with p are output. The function returns the resulting output iterator.

Precondition: dimension()==2

```
template <class OutputItBoundaryEdges>
```

```
OutputItBoundaryEdges
```

```
      cdt.get_boundary_of_conflicts( Point p,
                                     OutputItBoundaryEdges eit,
                                     Face_handle start)
```

OutputItBoundaryEdges stands for an output iterator with *Edge* as value type. This functions outputs in the container pointed to by *eit*, the boundary of the zone in conflict with p . The boundary edges of the conflict zone are output in counter-clockwise order and each edge is described through the incident face which is not in conflict with p . The function returns the resulting output iterator.

Checking

```
bool              cdt.is_valid()
```

Checks if the triangulation is valid and if each constrained edge is consistently marked constrained in its two incident faces.

└────────── advanced ─────────┘

Flips

```
bool              cdt.is_flipable( Face_handle f, int i)
```

Determines if edge (f,i) can be flipped. Returns true if edge (f,i) is not constrained and the circle circumscribing f contains the vertex of $f \rightarrow neighbor(i)$ opposite to edge (f,i) .

```
void              cdt.flip( Face_handle& f, int i)
```

Flip f and $f \rightarrow neighbor(i)$.

```
void              cdt.propagating_flip( List_edges & edges)
```

Makes the triangulation constrained Delaunay by flipping edges. List edges contains an initial list of edges to be flipped. The returned triangulation is constrained Delaunay if the initial list contains at least all the edges of the input triangulation that failed to be constrained Delaunay. (An edge is said to be constrained Delaunay if it is either constrained or locally Delaunay.)

CGAL::Constrained_triangulation_2<Traits,Tds,Itag>

Definition

A constrained triangulation is a triangulation of a set of points which has to include among its edges a given set of segments joining the points. The given segments are called *constraints* and the corresponding edges in the triangulation are called *constrained edges*.

The endpoints of constrained edges are of course vertices of the triangulation. However the triangulation may include other vertices as well. There are three versions of constrained triangulations

- In the basic version, the constrained triangulation does not handle intersecting constraints, and the set of input constraints is required to be a set of segments that do not intersect except possibly at their endpoints. Any number of constrained edges are allowed to share the same endpoint. Vertical constrained edges are allowed as well as constrained edges with null length.
- The two other versions support intersecting input constraints. In those versions, input constraints are allowed to be intersecting, overlapping or partially overlapping segments. The triangulation introduces additional vertices at each point which is a proper intersection point of two constraints. A single constraint intersecting other constraints will then appear as the union of several constrained edges of the triangulation. The two versions dealing with intersecting constraints, slightly differ in the way intersecting constraints are dealt with.
 - One of them is designed to be robust when predicates are evaluated exactly but constructions (i. e. intersection computations) are approximate.
 - The other one is designed to be used with an exact arithmetic (meaning exact evaluation of predicates and exact computation of intersections.) This last version finds its full efficiency when used in conjunction with a constraint hierarchy data structure as provided in the class *Constrained_triangulation_plus_2*. See section 35.9.

The class *Constrained_triangulation_2<Traits,Tds,Itag>* of the CGAL library implements constrained triangulations. The template parameter *Traits* stands for a geometric traits class. It has to be a model of the concept *TriangulationTraits_2*. When intersection of input constraints are supported, the geometric traits class is required to provide additional function object types to compute the intersection of two segments. It has then to be a model of the concept *ConstrainedTriangulationTraits_2*. The template parameter *Tds* stands for a triangulation data structure class that has to be a model of the concept *TriangulationDataStructure_2*. The third parameter *Itag* is the intersection tag which serves to choose between the different strategies to deal with constraints intersections. CGAL provides three valid types for this parameter :

CGAL::No_intersection_tag disallows intersections of input constraints,

CGAL::Exact_predicates_tag is to be used when the traits class provides exact predicates but approximate constructions of the intersection points.

CGAL::Exact_intersections_tag is to be used in conjunction with an exact arithmetic type.

The information about constrained edges is stored in the faces of the triangulation. Thus the nested *Face* type of a constrained triangulation offers additional functionalities to deal with this information. These additional

functionalities induce additional requirements on the base face class plugged into the triangulation data structure of a constrained Delaunay triangulation. The base face of a constrained Delaunay triangulation has to be a model of the concept *ConstrainedTriangulationFaceBase_2*.

CGAL provides default instantiations for the template parameters *Tds* and *Itag*, and for the *ConstrainedTriangulationFaceBase_2*. If *Gt* is the geometric traits parameter, the default for *ConstrainedTriangulationFaceBase_2* is the class *CGAL::Constrained_triangulation_face_base_2<Gt>* and the default for the triangulation data structure parameter is the class *CGAL::Triangulation_data_structure_2 < CGAL::Triangulation_vertex_base_2<Gt>, CGAL::Constrained_triangulation_face_base_2<Gt> >*. The default intersection tag is *CGAL::No_intersection_tag*.

```
#include <CGAL/Constrained_triangulation_2.h>
```

Inherits From

Triangulation_2<Traits,Tds>

Types

```
typedef std::pair<Point,Point>
```

Constraint;

The type of input constraints

```
typedef Itag
```

Intersection_tag;

The intersection tag which decides how intersections between input constraints are dealt with.

Creation

```
Constrained_triangulation_2<Traits,Tds,Itag> ct;
```

default constructor.

```
Constrained_triangulation_2<Traits,Tds,Itag> ct( Constrained_triangulation_2 ct1);
```

Copy constructor, all faces and vertices are duplicated and the constrained status of edges is copied.

```
template<class InputIterator>
```

```
Constrained_triangulation_2<Traits,Tds,Itag> ct( InputIterator first, InputIterator last, Traits t=Traits());
```

A templated constructor which introduces and builds a constrained triangulation with constrained edges in the range *[first, last)*.

Precondition: The *value_type* of *first* and *last* is *Constraint*.

Queries

bool *ct.is_constrained(Edge e)*

Returns true if edge *e* is a constrained edge.

bool *ct.are_there_incident_constraints(Vertex_handle v)*

Returns true if at least one of the edges incident to vertex *v* is constrained.

template<class OutputItEdges>

OutputItEdges *ct.incident_constraints(Vertex_handle v, OutputItEdges out)*

OutputItEdges is an output iterator with *Edge* as value type. Outputs the constrained edges incident to *v* in the sequence pointed to by *out* and returns the resulting output iterator.

Insertion and removal

Vertex_handle *ct.insert(Point p, Face_handle f = Face_handle())*

Inserts point *p* and restores the status (constrained or not) of all the touched edges. If present *f* is used as an hint for the location of *p*.

Vertex_handle *ct.insert(Point p, Locate_type& lt, Face_handle loc, int li)*

Same as above except that the location of the point *p* to be inserted is assumed to be given by *(lt,loc,i)*.

Vertex_handle *ct.push_back(Point p)*

Equivalent to *insert(p)*.

template < class InputIterator >

std::ptrdiff_t *ct.insert(InputIterator first, InputIterator last)*

Inserts the points in the range *[first, last)*. Returns the number of inserted points.

Precondition: The *value_type* of *first* and *last* is *Point*.

void *ct.insert_constraint(Point a, Point b)*

Inserts points *a* and *b*, and inserts segment *ab* as a constraint. Removes the faces crossed by segment *ab* and creates new faces instead. If a vertex *c* lies on segment *ab*, constraint *ab* is replaced by the two constraints *ac* and *cb*. Apart from the insertion of *a* and *b*, the algorithm runs in time proportional to the number of removed triangles.

Precondition: The relative interior of segment *ab* does not intersect the relative interior of another constrained edge.

void *ct.push_back(Constraint c)*

Inserts constraints *c* as above.

void *ct.insert_constraint(Vertex_handle va, Vertex_handle vb)*

Inserts the line segment *s* whose endpoints are the vertices *va* and *vb* as a constrained edge *e*. The triangles intersected by *s* are removed and new ones are created.

void *ct.remove(Vertex_handle v)*

Removes a vertex *v*.

Precondition: Vertex *v* is not incident to a constrained edge.

void *ct.remove_incident_constraints(Vertex_handle v)*

Make the edges incident to vertex *v* unconstrained edges.

void *ct.remove_constrained_edge(Face_handle f, int i)*

Make edge *(f,i)* no longer constrained.

┌────────── *advanced* ───────────┐
|
bool *ct.is_valid(bool verbose = false, int level = 0)*

Checks the validity of the triangulation and the consistency of the constrained marks in edges.

└────────── *advanced* ───────────┘

I/O

ostream & *ostream& os << Constrained_triangulation_2<Traits,Tds> Ct*

Writes the triangulation and, for each face *f*, and integers *i=0,1,2*, write “C” or “N” depending whether edge *(f,i)* is constrained or not.

The class *Constrained_triangulation_plus_2<Tr>* implements a constrained triangulation with an additional data structure called the constraint hierarchy that keeps track of the input constraints and of their refinement in the triangulation.

The class *Constrained_triangulation_plus_2<Tr>* inherits from its template parameter *Tr*, which has to be instantiated by a constrained or constrained Delaunay triangulation.

According to its intersection tag, the base class will support intersecting input constraints or not. When intersections of input constraints are supported, the base class constructs a triangulation of the arrangement of the constraints, introducing new vertices at each proper intersection point and refining the input constraints into sub-constraints which are edges (more precisely constrained edges) of the triangulation. In this context, the constraint hierarchy keeps track of the input constraints and of their refinement in the triangulation. This data structure maintains for each input constraints the sequence of intersection vertices added on this constraint. The constraint hierarchy also allows the user to retrieve the set of constrained edges of the triangulation, and for each constrained edge, the set of input constraints that overlap it.

```
#include <CGAL/Constrained_triangulation_plus_2.h>
```

Inherits From

Tr

Types

<i>typedef Tr</i>	<i>Triangulation;</i>	the triangulation base class.
<i>typedef Itag</i>	<i>Intersection_tag;</i>	the intersection tag.s

Constrained_triangulation_plus_2<Tr>:: Constraint_iterator

An iterator to visit all the input constraints. The order of visit is arbitrary. The value type of this iterator is a pair *std::pair<Vertex_handle, Vertex_handle>* corresponding to the endpoints of the constraint.

Constrained_triangulation_plus_2<Tr>:: Subconstraint_iterator

An iterator to visit all the sub-constraints of the triangulation. The order of visit is arbitrary. The value type of this iterator is a pair *std::pair<Vertex_handle, Vertex_handle>* corresponding to the vertices of the sub-constraint.

Constrained_triangulation_plus_2<Tr>:: Vertices_in_constraint_iterator

An iterator on the vertices of the chain of triangulation edges representing a constraint. The value type of this iterator is *Vertex_handle*.

<i>typedef</i>	<i>Context</i> ;	This type is intended to describe a constraint enclosing a sub-constraint and the position of the sub-constraint in this constraint. It provides three member functions <i>vertices_begin()</i> , <i>vertices_end()</i> and <i>current()</i> returning iterators of the type <i>Vertices_in_constraint_iterator</i> on the sequence of vertices of the enclosing constraint. These iterators point respectively on the first vertex of the enclosing constraint, past the last vertex and on the first vertex of the sub-constraint.
<i>typedef</i>	<i>Context_iterator</i> ;	An iterator on constraints enclosing a given sub-constraint. The value type of this iterator is <i>Context</i> .

Creation

Constrained_triangulation_plus_2<Tr> *ctp*(*Geom_traits* gt=*Geom_traits*());

Introduces an empty triangulation.

Constrained_triangulation_plus_2<Tr> *ctp*(*Constrained_triangulation_plus_2* ct);

Copy constructor.

Constrained_triangulation_plus_2<Tr> *ctp*(*std::list*<*Constrained*>& lc, *Geom_traits* t = *Geom_traits*());

Introduces and builds a constrained triangulation from the list of constraints *lc*.

template<*class InputIterator*>
Constrained_triangulation_plus_2<Tr> *ctp*(*InputIterator* first,
InputIterator last,
Geom_traits gt= *Geom_traits*())

Introduces and builds a constrained triangulation from the constraints in the range *[first, last)*.
Precondition: The *value_type* of *first* and *last* is *Constraint*.

void *~ctp*() Destructor. All vertices and faces are deleted. The constraint hierarchy is deleted.

Assignment

Constrained_triangulation_plus_2

ctp = *Constrained_triangulation_plus_2* tr

Assignment. All the vertices and faces are duplicated. The constraint hierarchy is also duplicated.

void *ctp.swap(Constrained_triangulation_plus_2 tr)*

The triangulations *tr* and *ctp* are swapped. This operation should be preferred to *ctp = tr* or to *t(tr)* if *tr* is deleted after that.

Insertion and Removal

The class *Constrained_triangulation_plus_2<Tr>* overwrites the following insertion and removal member functions for points and constraints.

Vertex_handle *ctp.insert(Point p, Face_handle start = Face_handle())*

Inserts point *p* as a vertex of the triangulation.

Vertex_handle *ctp.insert(Point p, Locate_type lt, Face_handle loc, int li)*

inserts a point *p* whose location is assumed to be given by *(lt,loc,li)*.

Vertex_handle *ctp.push_back(Point p)*

Equivalent to *insert(p)*.

template < class InputIterator >
size_type *ctp.insert(InputIterator first, InputIterator last)*

Inserts the points in the range *[first, last)*. Returns the number of inserted points.

Precondition: The *value_type* of *first* and *last* is *Point*.

void *ctp.insert_constraint(Point a, Point b)*

Inserts the constraint segment *ab* in the triangulation.

void *ctp.push_back(Constraint c)*

Inserts the constraint *c*.

void *ctp.insert_constraint(Vertex_handle va, Vertex_handle vb)*

Inserts a constraint whose endpoints are the vertices pointed by *va* and *vb* in the triangulation.

<i>void</i>	<i>ctp.remove_constraint(Vertex_handle va, Vertex_handle vb)</i>	<p>Removes the constraint joining the vertices pointed by <i>va</i> and <i>vb</i>.</p> <p><i>Precondition:</i> <i>va</i> and <i>vb</i> have to refer to the endpoint vertices of an input constraint.</p>
Queries		
<i>Constraint_iterator</i>	<i>ctp.constraints_begin()</i>	Returns a <i>Constraint_iterator</i> pointing on the first constraint.
<i>Constraint_iterator</i>	<i>ctp.constraints_end()</i>	Returns a <i>Constraint_iterator</i> pointing past the last constraint.
<i>Subconstraint_iterator</i>	<i>ctp.subconstraints_begin()</i>	Returns a <i>Subconstraint_iterator</i> pointing on the first sub-constraint.
<i>Subconstraint_iterator</i>	<i>ctp.subconstraints_end()</i>	Returns a <i>Subconstraint_iterator</i> pointing past the last sub-constraint.
<i>int</i>	<i>ctp.number_of_enclosing_constraints(Vertex_handle va, Vertex_handle vb)</i>	<p>Returns the number of constraints enclosing the sub-constraint (<i>va,vb</i>).</p> <p><i>Precondition:</i> <i>va</i> and <i>vb</i> refer to the vertices of a constrained edge of the triangulation.</p>
<i>Context</i>	<i>ctp.context(Vertex_handle va, Vertex_handle vb)</i>	<p>Returns the <i>Context</i> relative to one of the constraint enclosing the sub-constraint (<i>va,vb</i>).</p> <p><i>Precondition:</i> <i>va</i> and <i>vb</i> refer to the vertices of a constrained edge of the triangulation.</p>
<i>Context_iterator</i>	<i>ctp.contexts_begin(Vertex_handle va, Vertex_handle vb)</i>	<p>Returns an iterator pointing on the first <i>Context</i> of the sequence of <i>Contexts</i> corresponding to the constraints enclosing the sub-constraint(<i>va,vb</i>).</p> <p><i>Precondition:</i> <i>va</i> and <i>vb</i> refer to the vertices of a constrained edge of the triangulation.</p>
<i>Context_iterator</i>	<i>ctp.contexts_end(Vertex_handle va, Vertex_handle vb)</i>	<p>Returns an iterator past the last <i>Context</i> of the sequence of <i>Contexts</i> corresponding to the constraints enclosing the (<i>va,vb</i>).</p> <p><i>Precondition:</i> <i>va</i> and <i>vb</i> refer to the vertices of a constrained edge of the triangulation.</p>

Vertices_in_constraint_iterator

ctp.vertices_in_constraint_begin(Vertex_handle va, Vertex_handle vb)

Returns an iterator on the first vertex on the constraint (*va,vb*)

Precondition: *va* and *vb* refer to the vertices of an input constraint.

Vertices_in_constraint_iterator

ctp.vertices_in_constraint_end(Vertex_handle va, Vertex_handle vb)

Returns an iterator past the last vertex on the constraint (*va,vb*)

Precondition: *va* and *vb* refer to the vertices of an input constraints.

DelaunayTriangulationTraits_2

Definition

In addition to the requirements of the concept *TriangulationTraits_2* described page 2378, the concept *DelaunayTriangulationTraits_2* provide a predicate to check the empty circle property. The corresponding predicate type is called type *Side_of_oriented_circle_2*.

The additional types *Line_2*, *Ray_2* and the constructor objects *Construct_ray_2* *Construct_circumcenter_2*, *Construct_bisector_2*, *Construct_midpoint* are used to build the dual Voronoi diagram and are required only if the dual functions are called. The additional predicate type *Compare_distance_2* is required if calls to *nearest_vertex(..)* are issued.

Refines

TriangulationTraits_2

Types

DelaunayTriangulationTraits_2:: Line_2 The line type. This type is required only if some dual functions are called.

DelaunayTriangulationTraits_2:: Ray_2 The type for ray. This type is required only if some dual functions are called.

DelaunayTriangulationTraits_2:: Side_of_oriented_circle_2

Predicate type. Provides the operator :
Oriented_side operator()(Point p, Point q, Point r, Point s) which takes four points *p,q,r,s* as arguments and returns *ON_POSITIVE_SIDE*, *ON_NEGATIVE_SIDE* or *ON_ORIENTED_BOUNDARY* according to the position of points *s* with respect to the oriented circle through *p,q* and *r*.

DelaunayTriangulationTraits_2:: Compare_distance_2

Predicate type. Provides the operator :
Comparison_result operator()(Point_2 p, Point_2 q, Point_2 r) which returns *SMALLER*, *EQUAL* or *LARGER* according to the distance between *p* and *q* being smaller, equal or larger than the distance between *p* and *r*. This type is only require if *nearest_vertex* queries are issued.

DelaunayTriangulationTraits_2:: Construct_circumcenter_2

Constructor object. Provides the operator :
Point_2 operator()(Point_2 p, Point_2 q, Point_2 r) which returns the circumcenter of the three points *p, q* and *r*. This type is required only if functions relative to the dual Voronoi diagram are called.

DelaunayTriangulationTraits_2:: Construct_bisector_2

Constructor object. Provides the operator :
Line_2 operator()(Point_2 p, Point_2 q) which constructs the bisector line of points p and q . This type is required only if functions relative to the dual Voronoi diagram are called.

DelaunayTriangulationTraits_2:: Construct_ray_2

A constructor object to build a ray from a point and a line.
Provides :
Ray_2 operator() (Point_2 p, Line_2 l);

Creation

DelaunayTriangulationTraits_2 traits; default constructor.
DelaunayTriangulationTraits_2 traits(dtt); copy constructor
DelaunayTriangulationTraits_2 traits = traits2

Assignment operator.

Access to predicate and constructor objects

Side_of_oriented_circle_2 traits.side_of_oriented_circle_2_object()

The following functions are required only if member functions of the Delaunay triangulation relative to the dual Voronoi diagram are called. *Compare_distance_2 traits.compare_distance_2_object()*

Construct_circumcenter_2 traits.construct_circumcenter_2_object()

Construct_bisector_2 traits.construct_bisector_2_object()

Construct_direction_2 traits.construct_direction_2_object()

Construct_ray_2 traits.construct_ray_2_object()

TriangulationTraits_2

CGAL::Delaunay_triangulation_2<Traits,Tds>

Definition

The class *Delaunay_triangulation_2<Traits,Tds>* is designed to represent the Delaunay triangulation of a set of points in a plane. A Delaunay triangulation of a set of points is a triangulation of the sets of points that fulfills the following *empty circle property* (also called *Delaunay property*): the circumscribing circle of any facet of the triangulation contains no point of the set in its interior. For a point set with no case of co-circularity of more than three points, the Delaunay triangulation is unique, it is the dual of the Voronoi diagram of the points.

```
#include <CGAL/Delaunay_triangulation_2.h>
```

Parameters

The template parameter *Tds* is to be instantiated with a model of *TriangulationDataStructure_2*. CGAL provides a default instantiation for this parameter, which is the class *CGAL::Triangulation_data_structure_2 <CGAL::Triangulation_vertex_base_2<Traits>, CGAL::Triangulation_face_base_2<Traits> >*.

The geometric traits *Traits* is to be instantiated with a model of *DelaunayTriangulationTraits_2*. The concept *DelaunayTriangulationTraits_2* refines the concept *TriangulationTraits_2*, providing a predicate type to check the empty circle property.

Changing this predicate type allows to build Delaunay triangulations for different metrics such that L_1 or L_∞ or any metric defined by a convex object. However, the user of an exotic metric must be careful that the constructed triangulation has to be a triangulation of the convex hull which means that convex hull edges have to be Delaunay edges. This is granted for any smooth convex metric (like L_2) and can be ensured for other metrics (like L_∞) by the addition to the point set of well chosen sentinel points. The concept of *DelaunayTriangulationTraits_2* is described page [2353](#).

When dealing with a large triangulations, the user is advised to encapsulate the Delaunay triangulation class into a triangulation hierarchy, which means to use the class *Triangulation_hierarchy_2<Tr>* with the template parameter instantiated with *Delaunay_triangulation_2<Traits,Tds>*. The triangulation hierarchy will then offer the same functionalities but be much more efficient for locations and insertions.

Inherits From

Triangulation_2<Traits,Tds>

Types

Inherits all the types defined in *Triangulation_2<Traits,Tds>*.

Creation

```
Delaunay_triangulation_2<Traits,Tds> dt( Traits gt = Traits());
```

default constructor.

Delaunay_triangulation_2<*Traits*,*Tds*> *dt*(*tr*);

copy constructor. All the vertices and faces are duplicated.

Insertion and Removal

The following insertion and removal functions overwrite the functions inherited from the class *Triangulation_2*<*Traits*,*Tds*> to maintain the Delaunay property.

In the degenerate case when there are co-circular points, the Delaunay triangulation is known not to be uniquely defined. In this case, CGAL chooses a particular Delaunay triangulation using a symbolic perturbation scheme [DT03].

Vertex_handle *dt.insert*(*Point* *p*, *Face_handle* *f*=*Face_handle*()

inserts point *p*. If point *p* coincides with an already existing vertex, this vertex is returned and the triangulation is not updated. Optional parameter *f* is used to initialize the location of *p*.

Vertex_handle *dt.insert*(*Point* *p*, *Locate_type*& *lt*, *Face_handle* *loc*, *int* *li*)

inserts a point *p*, the location of which is supposed to be given by (*lt*,*loc*,*li*), see the description of member function *locate* in class *Triangulation_2*<*Traits*,*Tds*>.

Vertex_handle *dt.push_back*(*Point* *p*)

equivalent to *insert*(*p*).

template < *class InputIterator* >

std::ptrdiff_t *dt.insert*(*InputIterator* *first*, *InputIterator* *last*)

inserts the points in the range [*first*, *last*). Returns the number of inserted points.

Precondition: The *value_type* of *first* and *last* is *Point*.

void *dt.remove*(*Vertex_handle* *v*)

removes the vertex from the triangulation.

Note that the other modifier functions of *Triangulation_2*<*Traits*,*Tds*> are not overwritten. Thus a call to *insert_in_face*, *insert_in_edge*, *insert_outside_convex_hull*, *insert_outside_affine_hull* or *flip* on a valid Delaunay triangulation might lead to a triangulation which is no longer a Delaunay triangulation.

Displacement

Vertex_handle *dt.move_if_no_collision(Vertex_handle v, Point p)*

if there is not already another vertex placed on p , the triangulation is modified such that the new position of vertex v is p , and v is returned. Otherwise, the triangulation is not modified and the vertex at point p is returned.

Precondition: Vertex v must be finite.

Vertex_handle *dt.move(Vertex_handle v, Point p)*

same as above if there is no collision. Otherwise, v is deleted and the vertex placed on p is returned.

Precondition: Vertex v must be finite.

Queries

Vertex_handle *dt.nearest_vertex(Point p, Face_handle f=Face_handle())*

returns any nearest vertex of p . The implemented function begins with a location step and f may be used to initialize the location.

template <class OutputItFaces, class OutputItBoundaryEdges>

std::pair<OutputItFaces,OutputItBoundaryEdges>

dt.get_conflicts_and_boundary(Point p,
OutputItFaces fit,
OutputItBoundaryEdges eit,
Face_handle start)

OutputItFaces is an output iterator with *Face_handle* as value type. *OutputItBoundaryEdges* stands for an output iterator with *Edge* as value type. This members function outputs in the container pointed to by *fit* the faces which are in conflict with point p i. e. the faces whose circumcircle contains p . It outputs in the container pointed to by *eit* the the boundary of the zone in conflict with p . The boundary edges of the conflict zone are output in counter-clockwise order and each edge is described through its incident face which is not in conflict with p . The function returns in a *std::pair* the resulting output iterators.

Precondition: *dimension()==2*

template <class OutputItFaces>

OutputItFaces *dt.get_conflicts(Point p, OutputItFaces fit, Face_handle start)*

same as above except that only the faces in conflict with p are output. The function returns the resulting output iterator.

Precondition: *dimension()==2*

```
template <class OutputItBoundaryEdges>
OutputItBoundaryEdges
```

```
dt.get_boundary_of_conflicts( Point p,
                             OutputItBoundaryEdges eit,
                             Face_handle start)
```

OutputItBoundaryEdges stands for an output iterator with *Edge* as value type. This function outputs in the container pointed to by *eit*, the boundary of the zone in conflict with *p*. The boundary edges of the conflict zone are output in counterclockwise order and each edge is described through the incident face which is not in conflict with *p*. The function returns the resulting output iterator.

Voronoi diagram

The following member functions provide the elements of the dual Voronoi diagram.

Point *dt.dual(Face_handle f)* Returns the center of the circle circumscribed to face *f*.
Precondition: *f* is not infinite

Object *dt.dual(Edge e)* returns a segment, a ray or a line supported by the bisector of the endpoints of *e*. If faces incident to *e* are both finite, a segment whose endpoints are the duals of each incident face is returned. If only one incident face is finite, a ray whose endpoint is the dual of the finite incident face is returned. Otherwise both incident faces are infinite and the bisector line is returned.

Object *dt.dual(Edge_circulator ec)*

Idem

Object *dt.dual(Edge_iterator ei)* Idem

```
template < class Stream>
Stream&
```

dt.draw_dual(Stream & ps) output the dual Voronoi diagram to stream *ps*.

Predicates

Oriented_side *dt.side_of_oriented_circle(Face_handle f, Point p)*

Returns the side of *p* with respect to the circle circumscribing the triangle associated with *f*

————— advanced —————

Miscellaneous

The checking function *is_valid()* is also overwritten to additionally test the empty circle property.

bool dt.is_valid(bool verbose = false, int level = 0)

tests the validity of the triangulation as a *Triangulation_2* and additionally tests the Delaunay property. This method is mainly useful for debugging Delaunay triangulation algorithms designed by the user.

_____ *advanced* _____

CGAL::Triangulation_2<Traits,Tds>,
TriangulationDataStructure_2,
DelaunayTriangulationTraits_2,
Triangulation_hierarchy_2<Tr>.

Implementation

Insertion is implemented by inserting in the triangulation, then performing a sequence of Delaunay flips. The number of flips is $O(d)$ if the new vertex is of degree d in the new triangulation. For points distributed uniformly at random, insertion takes time $O(1)$ on average.

Removal calls the removal in the triangulation and then re-triangulates the hole in such a way that the Delaunay criterion is satisfied. Removal of a vertex of degree d takes time $O(d^2)$. The degree d is $O(1)$ for a random vertex in the triangulation.

After a point location step, the nearest neighbor is found in time $O(n)$ in the worst case, but in time $O(1)$ for vertices distributed uniformly at random and any query point.

CGAL::Triangulation_2<Traits,Tds>::Locate_type

Definition

The enum *Locate_type* is defined by the *Triangulation_2<Traits,Tds>* class to specify which case occurs when locating a point in the triangulation.

```
enum Locate_type { VERTEX=0, EDGE, FACET, OUTSIDE_CONVEX_HULL, OUTSIDE_AFFINE_HULL};
```

The locate type is :

VERTEX when the located point coincides with a vertex of the triangulation

EDGE when the point is in the relative interior of an edge

FACET when the point is in the interior of a facet

OUTSIDE_CONVEX_HULL when the point is outside the convex hull but in the affine hull of the current triangulation

OUTSIDE_AFFINE_HULL when the point is outside the affine hull of the current triangulation.

CGAL::Triangulation_2<Traits,Tds>.

RegularTriangulationFaceBase_2

Definition

The regular triangulation of a set of weighted points does not necessarily have one vertex for each of the input points. Some of the input weighted points have no cell in the dual power diagrams and therefore do not correspond to a vertex of the regular triangulation. Those weighted points are said to be *hidden* points. A point which is hidden at a given time may appear later as a vertex of the regular triangulation upon removal of some other weighted point. Therefore, hidden points have to be stored somewhere. The regular triangulation stores those hidden points in special vertices called *hidden* vertices.

A hidden point can appear as a vertex of the triangulation only when the two-dimensional face where its point component is located (the face which hides it) is removed. Therefore we decided to store in each face of a regular triangulation the list of hidden vertices whose points are located in the face. Thus points hidden by a face are easily reinserted in the triangulation when the face is removed.

The base face of a regular triangulation has to be a model of the concept `RegularTriangulationFaceBase_2`, which refines the concept `TriangulationFaceBase_2` by adding in the face a list to store hidden vertices.

Refines

`TriangulationFaceBase_2`

Types

RegularTriangulationTraits_2

Definition

The concept `RegularTriangulationTraits_2` describe the requirements for the traits class of regular triangulations. It refines the concept `TriangulationTraits_2` providing the type `Weighted_point_2` and the *power-test* predicate on those weighted points. A weighted point is basically a point augmented with a scalar weight. It can be seen as a circle when the weight is interpreted as a square radius. The *power-test* on weighted points is the fundamental test to build regular triangulations as the *side_of_oriented_circle* test is the fundamental test of Delaunay triangulations.

Refines

`TriangulationTraits_2`

Types

`RegularTriangulationTraits_2::Bare_point` Another name for the point type.

`RegularTriangulationTraits_2::Weighted_point_2`

The weighted point type, it has to be a model of the concept `WeightedPoint`.

`RegularTriangulationTraits_2::Power_test_2`

A predicate object type. Must provide the operators:

— `Oriented_side operator() (Weighted_point_2 p, Weighted_point_2 q, Weighted_point_2 r, Weighted_point_2 s)` which is the power test for points p , q , r and s .

Precondition: the bare points corresponding to p , q , r are not collinear.

— `Oriented_side operator() (Weighted_point_2 p, Weighted_point_2 q, Weighted_point_2 r)` which is the degenerated power test for collinear points p , q , r .

Precondition: the bare points corresponding to p , q , r are collinear and $p \neq q$.

— `Oriented_side operator() (Weighted_point_2 p, Weighted_point_2 q)` which is the degenerated power test for weighted points p and q whose corresponding bare-points are identical.

Precondition: the bare points corresponding to p and q are identical.

The following type/predicate is required if a call to *nearest_power_vertex* is issued:

`RegularTriangulationTraits_2::Compare_power_distance_2`

A predicate object type. Must provide the operator:

`Comparison_result operator()(Bare_point p, Weighted_point_2 q, Weighted_point_2 r)`, which compares the power distance between p and q to the power distance between p and r .

A constructor object which constructs the weighted circumcenter of three weighted points. Provides the operator *Bare_point operator()* (*Weighted_point_2 p, Weighted_point_2 q, Weighted_point_2 r*);

A constructor type which constructs the radical axis of two weighted points. Provides the operator :
Line_2 operator() (*Weighted_point_2 p, Weighted_point_2 q*);

<i>Power_test_2</i>	<i>traits.power_test_2_object()</i>
<i>Compare_power_distance_2</i>	<i>traits.compare_power_distance_2_object()</i>
<i>Construct_weighted_circumcenter_2</i>	<i>traits.construct_weighted_circumcenter_2_object()</i>
<i>Construct_radical_axis_2</i>	<i>traits.construct_radical_axis_2_object()</i>

CGAL::Regular_triangulation_2<Traits,Tds>

Definition

The class *Regular_triangulation_2<Traits,Tds>* is designed to maintain the regular triangulation of a set of weighted points.

Let $PW = \{(p_i, w_i), i = 1, \dots, n\}$ be a set of weighted points where each p_i is a point and each w_i is a scalar called the weight of point p_i . Alternatively, each weighted point (p_i, w_i) can be regarded as a two dimensional sphere with center p_i and radius $r_i = \sqrt{w_i}$.

The power diagram of the set PW is a planar partition such that each cell corresponds to sphere (p_i, w_i) of PW and is the locus of points p whose power with respect to (p_i, w_i) is less than its power with respect to any other sphere (p_j, w_j) in PW . The dual of this diagram is a triangulation whose domain covers the convex hull of the set $P = \{p_i, i = 1, \dots, n\}$ of center points and whose vertices are a subset of P . Such a triangulation is called a regular triangulation. The three points p_i, p_j and p_k of P form a triangle in the regular triangulation of PW iff there is a point p of the plane whose powers with respect to (p_i, w_i) , (p_j, w_j) and (p_k, w_k) are equal and less than the power of p with respect to any other sphere in PW .

Let us defined the power product of two weighted points (p_i, w_i) and (p_j, w_j) as:

$$\Pi(p_i, w_i, p_j, w_j) = p_i p_j^2 - w_i - w_j.$$

$\Pi(p_i, w_i, p_j, 0)$ is simply the power of point p_j with respect to the sphere (p_i, w_i) , and two weighted points are said to be orthogonal if their power product is null. The power circle of three weighted points (p_i, w_i) , (p_j, w_j) and (p_k, w_k) is defined as the unique circle (π, ω) orthogonal to (p_i, w_i) , (p_j, w_j) and (p_k, w_k) .

The regular triangulation of the sets PW satisfies the following *regular property* (which just reduces to the Delaunay property when all the weights are null): a triangle $p_i p_j p_k$ of the regular triangulation of PW is such that the power product of any weighted point (p_l, w_l) of PW with the power circle of (p_i, w_i) , (p_j, w_j) is (p_k, w_k) is positive or null. We call power test of the weighted point (p_l, w_l) with respect to the face $p_i p_j p_k$, the predicates testing the sign of the power product of (p_l, w_l) with respect to the power circle of (p_i, w_i) , (p_j, w_j) is (p_k, w_k) . This power product is given by the following determinant

$$\begin{vmatrix} 1 & x_i & y_i & x_i^2 + y_i^2 - w_i \\ 1 & x_j & y_j & x_j^2 + y_j^2 - w_j \\ 1 & x_k & y_k & x_k^2 + y_k^2 - w_k \\ 1 & x_l & y_l & x_l^2 + y_l^2 - w_l \end{vmatrix}$$

A pair of neighboring faces $p_i p_j p_k$ and $p_i p_j p_l$ is said to be locally regular (with respect to the weights in PW) if the power test of (p_l, w_l) with respect to $p_i p_j p_k$ is positive. A classical result of computational geometry establishes that a triangulation of the convex hull of P such that any pair of neighboring faces is regular with respect to PW , is a regular triangulation of PW .

Alternatively, the regular triangulation of the weighted points set PW can be obtained as the projection on the two dimensional plane of the convex hull of the set of three dimensional points $P' = \{(p_i, p_i^2 - w_i), i = 1, \dots, n\}$.

The vertices of the regular triangulation of a set of weighted points PW form only a subset of the set of center points of PW . Therefore the insertion of a weighted point in a regular triangulation does not necessarily imply the creation of a new vertex. If the new inserted point does not appear as a vertex in the regular triangulation, it is said to be hidden.

Hidden points are stored in special vertices called hidden vertices. A hidden point is considered as hidden by the facet of the triangulation where its point component is located : in fact, the hidden point can appear as vertex of the triangulation only if this facet is removed. Each face of a regular triangulation stores the list of hidden vertices whose points are located in the facet. When a facet is removed, points hidden by this facet are reinserted in the triangulation.

```
#include <CGAL/Regular_triangulation_2.h>
```

Parameters

The geometric traits parameter *Traits* has to be instantiated with a model of the concept *RegularTriangulationTraits_2*. The concept *RegularTriangulationTraits_2* refines the concept *TriangulationTraits_2* by adding the type *Weighted_point_2* to describe weighted points and the type *Power_test_2* to perform power tests on weighted points.

The *Tds* parameter has to be instantiated by a model of *TriangulationDataStructure_2*. The face base of a regular triangulation has to be a model of the concept *RegularTriangulationFaceBase_2*. while the vertex base class has to be a model of *RegularTriangulationVertexBase_2*. CGAL provides a default instantiation for the *Tds* parameter by the class *CGAL::Triangulation_data_structure_2 < CGAL::Regular_triangulation_vertex_base_2<Traits>, CGAL::Regular_Triangulation_face_base_2<Traits> >*.

Inherits From

Triangulation_2<Traits,Tds>

Types

```
typedef Traits::Distance      Distance;
```

```
typedef Traits::Line          Line;
```

```
typedef Traits::Ray           Ray;
```

```
typedef Traits::Bare_point     Bare_point;
```

```
typedef Traits::Weighted_point Weighted_point;
```

Regular_triangulation_2<Traits,Tds>:: All_vertices_iterator

An iterator that allows to enumerate the vertices that are not hidden.

Regular_triangulation_2<Traits,Tds>:: Finite_vertices_iterator

An iterator that allows to enumerate the finite vertices that are not hidden.

Regular_triangulation_2<Traits,Tds>:: Hidden_vertices_iterator

An iterator that allows to enumerate the hidden vertices.

Creation

```
Regular_triangulation_2<Traits,Tds> rt( Traits gt = Traits());
```

Introduces an empty regular triangulation *rt*.

```
Regular_triangulation_2<Traits,Tds> rt( Regular_triangulation_2 rt);
```

Copy constructor.

Insertion and Removal

```
Vertex_handle rt.insert( Weighted_point p, Face_handle f=Face_handle())
```

inserts weighted point *p* in the regular triangulation. If the point *p* does not appear as a vertex of the triangulation, the returned vertex is a hidden vertex. If given the parameter *f* is used as an hint for the place to start the location process of point *p*.

```
Vertex_handle rt.insert( Weighted_point p, Locate_type lt, Face_handle loc, int li)
```

insert a weighted point *p* whose bare-point is assumed to be located in *lt,loc,li*.

```
Vertex_handle rt.push_back( Point p)
```

 Equivalent to *insert(p)*.

```
template < class InputIterator >  
std::ptrdiff_t rt.insert( InputIterator first, InputIterator last)
```

inserts the weighted points in the range [*first*, *last*). Returns the number of created vertices.

Precondition: The *value_type* of *first* and *last* is *Weighted_point*.

```
void rt.remove( Vertex_handle v)
```

 removes the vertex from the triangulation.

Queries

```
template <class OutputItFaces, class OutputItBoundaryEdges, class OutputItHiddenVertices>  
CGAL::Triple<OutputItFaces,OutputItBoundaryEdges,OutputItHiddenVertices>
```

```
rt.get_conflicts_and_boundary_and_hidden_vertices( Weighted_point p,  
                                                    OutputItFaces fit,  
                                                    OutputItBoundaryEdges eit,  
                                                    OutputItHiddenVertices vit,
```

Face_handle start)

OutputItFaces is an output iterator with *Face_handle* as value type. *OutputItBoundaryEdges* stands for an output iterator with *Edge* as value type. *OutputItHiddenVertices* is an output iterator with *Vertex_handle* as value type. This member function outputs in the container pointed to by *fit* the faces which are in conflict with point *p* i. e. the faces whose power circles have negative power wrt. *p*. It outputs in the container pointed to by *eit* the boundary of the zone in conflict with *p*. It inserts the vertices that would be hidden by *p* into the container pointed to by *vit*. The boundary edges of the conflict zone are output in counter-clockwise order and each edge is described through its incident face which is not in conflict with *p*. The function returns in a *CGAL::Triple* the resulting output iterators.

Precondition: *dimension()==2*

```
template <class OutputItFaces, class OutputItBoundaryEdges>
std::pair<OutputItFaces,OutputItBoundaryEdges>
```

```
    rt.get_conflicts_and_boundary( Weighted_point p,
                                   OutputItFaces fit,
                                   OutputItBoundaryEdges eit,
                                   Face_handle start)
```

same as above except that only the faces in conflict with *p* and the boundary edges of the conflict zone are output via the corresponding output iterators. The function returns in a *std::pair* the resulting output iterators.

Precondition: *dimension()==2*

```
template <class OutputItFaces, class OutputItHiddenVertices>
std::pair<OutputItFaces,OutputItHiddenVertices>
```

```
    rt.get_conflicts_and_hidden_vertices( Weighted_point p,
                                           OutputItFaces fit,
                                           OutputItHiddenVertices vit,
                                           Face_handle start)
```

same as above except that only the faces in conflict with *p* and the vertices that would be hidden by *p* are output via the corresponding output iterators. The function returns in a *std::pair* the resulting output iterators.

Precondition: *dimension()==2*

```
template <class OutputItBoundaryEdges, class OutputItHiddenVertices>
std::pair<OutputItBoundaryEdges,OutputItHiddenVertices>
```

```
    rt.get_boundary_of_conflicts_and_hidden_vertices( Weighted_point p,
                                                       OutputItBoundaryEdges eit,
                                                       OutputItHiddenVertices vit,
```

Face_handle start)

same as above except that only the vertices that would be hidden by p and the boundary of the zone in conflict with p are output via the corresponding output iterators. The boundary edges of the conflict zone are output in counter-clockwise order and each edge is described through the incident face which is not in conflict with p . The function returns in a `std::pair` the resulting output iterators.

template <class OutputItFaces>
OutputItFaces

rt.get_conflicts(Point p, OutputItFaces fit, Face_handle start)

same as above except that only the faces in conflict with p are output. The function returns the resulting output iterator.
Precondition: `dimension()==2`

template <class OutputItBoundaryEdges>
OutputItBoundaryEdges

rt.get_boundary_of_conflicts(Point p, OutputItBoundaryEdges eit, Face_handle start)

same as above except that only the boundary edges of the conflict zone are output in counterclockwise order where each edge is described through the incident face which is not in conflict with p . The function returns the resulting output iterator.

template <class OutputItHiddenVertices>
OutputItHiddenVertices

rt.get_hidden_vertices(Point p, OutputItHiddenVertices vit, Face_handle start)

same as above except that only the vertices that would be hidden by p are output. The function returns the resulting output iterator.

Vertex_handle *rt.nearest_power_vertex(Bare_point p)*

Returns the vertex of the triangulation which is nearest to p with respect to the power distance. This means that the power of the query point p with respect to the weighted point in the nearest vertex is smaller than the power of p with respect to the weighted point in any other vertex. Ties are broken arbitrarily. The default constructed handle is returned if the triangulation is empty.

Access functions

<i>int</i>	<i>rt.number_of_vertices()</i>	returns the number of finite vertices that are not hidden.
<i>int</i>	<i>rt.number_of_hidden_vertices()</i>	
		returns the number of hidden vertices.
<i>Hidden_vertices_iterator</i>	<i>rt.hidden_vertices_begin()</i>	
		starts at an arbitrary hidden vertex.
<i>Hidden_vertices_iterator</i>	<i>rt.hidden_vertices_end()</i>	past the end iterator for the sequence of hidden vertices.
<i>Finite_vertices_iterator</i>	<i>rt.finite_vertices_begin()</i>	starts at an arbitrary unhidden finite vertex
<i>Finite_vertices_iterator</i>	<i>rt.finite_vertices_end()</i>	Past-the-end iterator
<i>All_vertices_iterator</i>	<i>rt.all_vertices_end()</i>	starts at an arbitrary unhidden vertex.
<i>All_vertices_iterator</i>	<i>rt.all_vertices_begin()</i>	past the end iterator.

Dual power diagram

The following member functions provide the elements of the dual power diagram.

<i>Point</i>	<i>rt.weighted_circumcenter(Face_handle f)</i>	
		returns the center of the circle orthogonal to the three weighted points corresponding to the vertices of face <i>f</i> . <i>Precondition:</i> <i>f</i> is not infinite
<i>Point</i>	<i>rt.dual(Face_handle f)</i>	same as <i>weighted_circumcenter</i>
<i>Object</i>	<i>rt.dual(Edge e)</i>	If both incident faces are finite, returns a segment whose endpoints are the duals of each incident face. If only one incident face is finite, returns a ray whose endpoint is the dual of the finite incident face and supported by the line which is the bisector of the edge's endpoints. If both incident faces are infinite, returns the line which is the bisector of the edge's endpoints otherwise.
<i>Object</i>	<i>rt.dual(Edge_circulator ec)</i>	
		Idem
<i>Object</i>	<i>rt.dual(Edge_iterator ei)</i>	
		Idem
<i>template < class Stream></i> <i>Stream&</i>	<i>rt.draw_dual(Stream & ps)</i>	
		output the dual power diagram to stream <i>ps</i> .

Predicates

Oriented_side *rt.power_test(Face_handle f, Weighted_point p)*

Returns the power test of *p* with respect to the power circle associated with *f*

┌────────── *advanced* ──────────┐

Miscellaneous

bool *rt.is_valid(bool verbose = false, int level = 0)*

Tests the validity of the triangulation as a *Triangulation_2* and additionally test the regularity of the triangulation. This method is useful to debug regular triangulation algorithms implemented by the user.

CGAL::Regular_triangulation_euclidean_traits_2<K,Weight>

Definition

Regular_triangulation_euclidean_traits_2<K,Weight> is a model for the concept *RegularTriangulationTraits_2*. This traits class is templated by a kernel class *K* and a weight type *Weight*. This class inherits from *K* and uses a *Weighted_point* type derived from the type *K::Point_2*.

Note that this template class is specialized for *CGAL::Exact_predicates_inexact_constructions_kernel*, so that it is as if *Regular_triangulation_filtered_traits_2* was used, i.e. you get filtered predicates automatically.

TriangulationFaceBase_2

Definition

The concept `TriangulationFaceBase_2` describes the requirements for the base face class of a triangulation data structure that is itself plugged into a basic triangulation or a Delaunay triangulation.

This concept refines the concept *TriangulationDSFaceBase_2* and could add geometric information. In fact, currently the triangulations of CGAL do not store any geometric information in the faces and, thus this concept is just equal to *TriangulationDSFaceBase_2* and only provided for symmetry with the vertex case.

TriangulationTraits_2

Definition

The concept `TriangulationTraits_2` describes the set of requirements to be fulfilled by any class used to instantiate the first template parameter of the class `Triangulation_2<Traits,Tds>`. This concept provides the types of the geometric primitives used in the triangulation and some function object types for the required predicates on those primitives.

Types

<code>TriangulationTraits_2:: Point_2</code>	The point type.
<code>TriangulationTraits_2:: Segment_2</code>	The segment type.
<code>TriangulationTraits_2:: Triangle_2</code>	The triangle type.
<code>TriangulationTraits_2:: Construct_segment_2</code>	A constructor object for <code>Segment_2</code> . Provides : <code>Segment_2 operator()(Point_2 p,Point_2 q)</code> , which constructs a segment from two points.
<code>TriangulationTraits_2:: Construct_triangle_2</code>	A constructor object for <code>Triangle_2</code> . Provides : <code>Triangle_2 operator()(Point_2 p,Point_2 q,Point_2 r)</code> , which constructs a triangle from three points.
<code>TriangulationTraits_2:: Less_x_2</code>	Predicate object. Provides the operator : <code>bool operator()(Point p, Point q)</code> which returns <i>true</i> if <i>p</i> is before <i>q</i> according to the <i>x</i> -ordering of points.
<code>TriangulationTraits_2:: Less_y_2</code>	Predicate object. Provides the operator : <code>bool operator()(Point p, Point q)</code> which returns <i>true</i> if <i>p</i> is before <i>q</i> according to the <i>y</i> -ordering of points.
<code>TriangulationTraits_2:: Compare_x_2</code>	Predicate object. Provides the operator : <code>Comparison_result operator()(Point p, Point q)</code> which returns <i>SMALLER</i> , <i>EQUAL</i> or <i>LARGER</i> according to the <i>x</i> -ordering of points <i>p</i> and <i>q</i> .
<code>TriangulationTraits_2:: Compare_y_2</code>	Predicate object. Provides the operator : <code>Comparison_result operator()(Point p, Point q)</code> which returns (<i>SMALLER</i> , <i>EQUAL</i> or <i>LARGER</i>) according to the <i>y</i> -ordering of points <i>p</i> and <i>q</i> .
<code>TriangulationTraits_2:: Orientation_2</code>	Predicate object. Provides the operator : <code>Orientation operator()(Point p, Point q, Point r)</code> which returns <i>LEFT_TURN</i> , <i>RIGHT_TURN</i> or <i>COLLINEAR</i> depending on <i>r</i> being, with respect to the oriented line <i>pq</i> , on the left side , on the right side or on the line.

TriangulationTraits_2:: Side_of_oriented_circle_2

Predicate object. Must provide the operator *Oriented_side operator()(Point p, Point q, Point r, Point s)* which takes four points *p,q,r,s* as arguments and returns *ON_POSITIVE_SIDE*, *ON_NEGATIVE_SIDE* or, *ON_ORIENTED_BOUNDARY* according to the position of points *s* with respect to the oriented circle through through *p,q* and *r*. This type is required only if the function *side_of_oriented_circle(Face_handle f, Point p)* is called.

TriangulationTraits_2:: Construct_circumcenter_2

Constructor object. Provides the operator :
Point operator()(Point p, Point q, Point r)
which returns the circumcenter of the three points *p, q* and *r*. This type is required only if the function *Point circumcenter(Face_handle f)* is called.

Creation

Only a default constructor, copy constructor and an assignment operator are required. Note that further constructors can be provided.
TriangulationTraits_2 traits; default constructor.
TriangulationTraits_2 traits(gtr); Copy constructor

TriangulationTraits_2 traits = gtr Assignment operator.

Predicate functions

The following functions give access to the predicate and constructor objects.

Construct_segment_2 traits.construct_segment_2_object()

Construct_triangle_2 traits.construct_triangle_2_object()

Comparison_x_2 traits.compare_x_2_object()

Comparison_y_2 traits.compare_y_2_object()

Orientation_2 traits.orientation_2_object()

Side_of_oriented_circle_2

traits.side_of_oriented_circle_2_object()

Required only if *side_of_oriented_circle* is called.

Construct_circumcenter_2

traits.construct_circumcenter_2_object()

Required only if *circumcenter* is called.

TriangulationVertexBase_2

Definition

The concept `TriangulationVertexBase_2` describes the requirements for the vertex base class of a triangulation data structure to be plugged in a basic, Delaunay or constrained triangulations.

The concept `TriangulationVertexBase_2` refines the concept `TriangulationDSVertexBase_2` adding geometric information : the vertex base of a triangulation stores a point.

Refines

`TriangulationDSVertexBase_2`

Types

`TriangulationVertexBase_2::Point`

Must be the same as the point type `TriangulationTraits_2::Point_2` defined by the geometric traits class of the triangulation.

Creation

`TriangulationVertexBase_2 v(Point p);` constructs a vertex embedded in point p .

`TriangulationVertexBase_2 v(Point p, Face_handle f);`
constructs a vertex embedded in point p and pointing on face f .

Access Functions

`Point v.point()` returns the point.

Setting

`void v.set_point(Point p)`
sets the point.

I/O

`istream& istream& is >> &v`

Inputs the non-combinatorial information given by the vertex: the point and other possible information.

ostream&

ostream& os << v

Outputs the non combinatorial operation given by the vertex: the point and other possible information.

Has Models

CGAL::TriangulationVertexBase_2<Traits>.

TriangulationDataStructure_2::Vertex

CGAL::Triangulation_vertex_base_2<Traits>

CGAL::Triangulation_2<Traits,Tds>

Definition

The class *Triangulation_2<Traits,Tds>* is the basic class designed to handle triangulations of set of points *A* in the plane.

Such a triangulation has vertices at the points of *A* and its domain covers the convex hull of *A*. It can be viewed as a planar partition of the plane whose bounded faces are triangular and cover the convex hull of *A*. The single unbounded face of this partition is the complementary of the convex hull of *A*.

In many applications, it is convenient to deal only with triangular faces. Therefore, we add to the triangulation a fictitious vertex, called the *infinite vertex* and we make each convex hull edge incident to an *infinite* face having as third vertex the *infinite vertex*. In that way, each edge is incident to exactly two faces and special cases at the boundary of the convex hull are simpler to deal with.

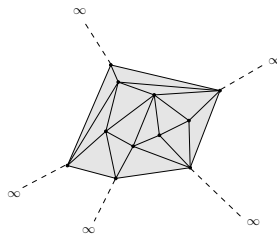

Figure 35.8: The infinite vertex.

The class *Triangulation_2<Traits,Tds>* implements this point of view and therefore considers the triangulation of the set of points as a set of triangular, finite and infinite faces. Although it is convenient to draw a triangulation as in figure 35.8, note that the *infinite vertex* has no significant coordinates and that no geometric predicate can be applied on it or on an infinite face.

A triangulation is a collection of vertices and faces that are linked together through incidence and adjacency relations. Each face give access to its three incident vertices and to its three adjacent faces. Each vertex give access to one of its incident faces.

The three vertices of a face are indexed with 0, 1 and 2 in counterclockwise order. The neighbor of a face are also indexed with 0,1,2 in such a way that the neighbor indexed by *i* is opposite to the vertex with the same index.

The triangulation class offer two functions *int cw(int i)* and *int ccw(int i)* which given the index of a vertex in a face compute the index of the next vertex of the same face in clockwise or counterclockwise order. Thus, for example the neighbor *neighbor(cw(i))* is the neighbor of *f* which is next to *neighbor(i)* turning clockwise around *f*. The face *neighbor(cw(i))* is also the first face encountered after *f* when turning clockwise around vertex *i* of *f* (see Figure 35.9).

```
#include <CGAL/Triangulation_2.h>
```

Parameters

The class *Triangulation_2<Traits,Tds>* has two template parameters. The first one *Traits* is the geometric traits, it is to be instantiated by a model of the concept *TriangulationTraits_2*.

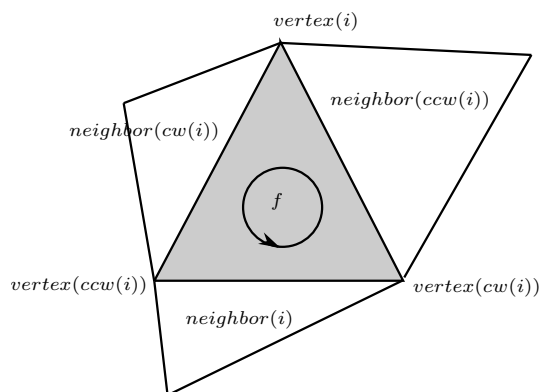

Figure 35.9: Vertices and neighbors.

The second parameter is the triangulation data structure, it has to be instantiated by a model of the concept *TriangulationDataStructure_2*. By default, the triangulation data structure is instantiated by `CGAL::Triangulation_data_structure_2 < CGAL::Triangulation_vertex_base_2<Gt>, CGAL::Triangulation_face_base_2<Gt> >>`.

Inherits From

<code>typedef Tds::size_type</code>	<code>size_type;</code>	Size type (an unsigned integral type)
<code>typedef Tds::difference_type</code>	<code>difference_type;</code>	Difference type (a signed integral type)

The vertices and faces of the triangulations are accessed through *handles*, *iterators* and *circulators*. The handles are models of the concept *Handle* which basically offers the two dereference operators `*` and `->`. The iterators and circulators are all bidirectional and non mutable. The circulators and iterators are convertible to handles with the same value type, so that whenever a handle appear in the parameter list of a function, an appropriate iterator or circulator can be passed as well.

The edges of the triangulation can also be visited through iterators and circulators, the edge circulators and iterators are also bidirectional and non mutable.

In the following, we called *infinite* any face or edge incident to the infinite vertex and the infinite vertex itself. Any other feature (face, edge or vertex) of the triangulation is said to be *finite*. Some iterators (the *All* iterators

) allows to visit finite or infinite feature while others (the *Finite* iterators) visit only finite features. Circulators visit infinite features as well as finite ones.

<code>typedef Tds::Vertex_handle</code>	<code>Vertex_handle;</code>	handle to a vertex
<code>typedef Tds::Face_handle</code>	<code>Face_handle;</code>	handle to a face
<code>typedef Tds::Face_iterator</code>	<code>All_faces_iterator;</code>	iterator over all faces.
<code>typedef Tds::Edge_iterator</code>	<code>All_edges_iterator;</code>	iterator over all edges
<code>typedef Tds::Vertex_iterator</code>	<code>All_vertices_iterator;</code>	iterator over all vertices
<code>Triangulation_2<Traits,Tds>:: Finite_faces_iterator</code>		iterator over finite faces.
<code>Triangulation_2<Traits,Tds>:: Finite_edges_iterator</code>		iterator over finite edges.
<code>Triangulation_2<Traits,Tds>:: Finite_vertices_iterator</code>		iterator over finite vertices.
<code>Triangulation_2<Traits,Tds>:: Point_iterator</code>		iterator over the points corresponding the finite vertices of the triangulation.
<code>Triangulation_2<Traits,Tds>:: Line_face_circulator</code>		circulator over all faces intersected by a line.
<code>Triangulation_2<Traits,Tds>:: Face_circulator</code>		circulator over all faces incident to a given vertex.
<code>Triangulation_2<Traits,Tds>:: Edge_circulator</code>		circulator over all edges incident to a given vertex.
<code>Triangulation_2<Traits,Tds>:: Vertex_circulator</code>		circulator over all vertices incident to a given vertex.

The triangulation class also defines the following enum type to specify which case occurs when locating a point in the triangulation.

```
enum Locate_type { VERTEX=0, EDGE, FACE, OUTSIDE_CONVEX_HULL, OUTSIDE_AFFINE_HULL};
```

The locate type is *OUTSIDE_CONVEX_HULL* when the point is outside the convex hull but in the affine hull of the current triangulation.

The locate type is *OUTSIDE_AFFINE_HULL* when the point is outside the affine hull of the current triangulation.

Creation

```
Triangulation_2<Traits,Tds> t;           default constructor.
Triangulation_2<Traits,Tds> t( Traits gt = Traits());
```

Introduces an empty triangulation *t*.

Triangulation_2<*Traits*,*Tds*> *t*(*Triangulation_2* *tr*);

Copy constructor. All the vertices and faces are duplicated. After the copy, *t* and *tr* refer to different triangulations : if *tr* is modified, *t* is not.

Triangulation_2 *t* = *tr*

Assignment. All the vertices and faces are duplicated. After the assignment, *t* and *tr* refer to different triangulations : if *tr* is modified, *t* is not.

void *t.swap*(*Triangulation_2*& *tr*)

The triangulations *tr* and *t* are swapped. *t.swap(tr)* should be preferred to *t = tr* or to *t(tr)* if *tr* is deleted after that.

void *t.clear*()

Deletes all faces and finite vertices resulting in an empty triangulation.

Access Functions

Geom_traits *t.geom_traits*()
TriangulationDataStructure_2

Returns a const reference to the triangulation traits object.

t.tds()

Returns a const reference to the triangulation data structure.

————— *advanced* —————

Non const access

The responsibility of keeping a valid triangulation belongs to the user when using advanced operations allowing a direct manipulation of the *tds*.

TriangulationDataStructure_2&

t.tds()

Returns a reference to the triangulation data structure.

This method is mainly a help for users implementing their own triangulation algorithms.

————— *advanced* —————

int *t.dimension*()

Returns the dimension of the convex hull.

size_type *t.number_of_vertices*()

Returns the number of finite vertices.

size_type *t.number_of_faces*()

Returns the number of finite faces.

Face_handle *t.infinite_face*()

a face incident to the *infinite_vertex*.

Vertex_handle *t.infinite_vertex*()

the *infinite_vertex*.

Vertex_handle *t.finite_vertex*()

a vertex distinct from the *infinite_vertex*.

Predicates

The class *Triangulation_2*<*Traits*,*Tds*> provides methods to test the finite or infinite character of any feature, and also methods to test the presence in the triangulation of a particular feature (edge or face).

bool t.is_infinite(Vertex_handle v) *true* iff *v* is the *infinite_vertex*.
bool t.is_infinite(Face_handle f) *true* iff face *f* is infinite.
bool t.is_infinite(Face_handle f, int i) *true* iff edge (*f,i*) is infinite.
bool t.is_infinite(Edge e) *true* iff edge *e* is infinite.
bool t.is_infinite(Edge_circulator ec) *true* iff edge **ec* is infinite.
bool t.is_infinite(Edge_iterator ei) *true* iff edge **ei* is infinite.

bool t.is_edge(Vertex_handle va, Vertex_handle vb)
true if there is an edge having *va* and *vb* as vertices.

bool t.is_edge(Vertex_handle va, Vertex_handle vb, Face_handle& fr, int & i)
as above. In addition, if *true* is returned, the edge with vertices *va* and *vb* is the edge *e=(fr,i)* where *fr* is a handle to the face incident to *e* and on the right side of *e* oriented from *va* to *vb*.

bool t.includes_edge(Vertex_handle va, Vertex_handle & vb, Face_handle& fr, int & i)
true if the line segment from *va* to *vb* includes an edge *e* incident to *va*. If *true*, *vb* becomes the other vertex of *e*, *e* is the edge (*fr,i*) where *fr* is a handle to the face incident to *e* and on the right side *e* oriented from *va* to *vb*.

bool t.is_face(Vertex_handle v1, Vertex_handle v2, Vertex_handle v3)
true if there is a face having *v1*, *v2* and *v3* as vertices.

bool t.is_face(Vertex_handle v1, Vertex_handle v2, Vertex_handle v3, Face_handle &fr)
as above. In addition, if *true* is returned, *fr* is a handle to the face with *v1*, *v2* and *v3* as vertices.

Queries

The class *Triangulation_2<Traits,Tds>* provides methods to locate a given point with respect to a triangulation. It also provides methods to locate a point with respect to a given finite face of the triangulation.

Face_handle t.locate(Point query, Face_handle f = Face_handle())

If the point *query* lies inside the convex hull of the points, a face that contains the query in its interior or on its boundary is returned.

If the point *query* lies outside the convex hull of the triangulation but in the affine hull, the returned face is an infinite face which is a proof of the point's location :

- for a two dimensional triangulation, it is a face (∞, p, q) such that *query* lies to the left of the oriented line *pq* (the rest of the triangulation lying to the right of this line).

- for a degenerate one dimensional triangulation it is the (degenerate one dimensional) face $(\infty, p, NULL)$ such that *query* and the triangulation lie on either side of *p*.

If the point *query* lies outside the affine hull, the returned *Face_handle* is *NULL*.

The optional *Face_handle* argument, if provided, is used as a hint of where the locate process has to start its search.

Face_handle *t.locate(Point query, Locate_type& lt, int& li, Face_handle h =Face_handle())*

Same as above. Additionally, the parameters *lt* and *li* describe where the query point is located. The variable *lt* is set to the locate type of the query. If *lt*==*VERTEX* the variable *li* is set to the index of the vertex, and if *lt*==*EDGE* *li* is set to the index of the vertex opposite to the edge. Be careful that *li* has no meaning when the query type is *FACE*, *OUTSIDE_CONVEX_HULL*, or *OUTSIDE_AFFINE_HULL* or when the triangulation is 0-dimensional.

Oriented_side *t.oriented_side(Face_handle f, Point p)*

Returns on which side of the oriented boundary of *f* lies the point *p*.
Precondition: *f* is finite.

Oriented_side *t.side_of_oriented_circle(Face_handle f, Point p)*

Returns on which side of the circumcircle of face *f* lies the point *p*. The circle is assumed to be counterclockwise oriented, so its positive side correspond to its bounded side. This predicate is available only if the corresponding predicates on points is provided in the geometric traits class.

Modifiers

The following operations are guaranteed to lead to a valid triangulation when they are applied on a valid triangulation.

void *t.flip(Face_handle f, int i)*

Exchanges the edge incident to *f* and *f->neighbor(i)* with the other diagonal of the quadrilateral formed by *f* and *f->neighbor(i)*.
Precondition: The faces *f* and *f->neighbor(i)* are finite faces and their union form a convex quadrilateral.

Vertex_handle *t.insert(Point p, Face_handle f = Face_handle())*

Inserts point *p* in the triangulation and returns the corresponding vertex.
If point *p* coincides with an already existing vertex, this vertex is returned and the triangulation remains unchanged.
If point *p* is on an edge, the two incident faces are split in two.
If point *p* is strictly inside a face of the triangulation, the face is split in three.
If point *p* is strictly outside the convex hull, *p* is linked to all visible points on the convex hull to form the new triangulation.
At last, if *p* is outside the affine hull (in case of degenerate 1-dimensional or 0-dimensional triangulations), *p* is linked all the other vertices to form a triangulation whose dimension is increased by one.
The last argument *f* is an indication to the underlying locate algorithm of where to start.

Vertex_handle *t.insert(Point p, Locate_type lt, Face_handle loc, int li)*

Same as above except that the location of the point *p* to be inserted is assumed to be given by *(lt,loc,i)* (see the description of the *locate* method above.)

Vertex_handle *t.push_back(Point p)*

Equivalent to *insert(p)*.

template < class InputIterator >
std::ptrdiff_t *t.insert(InputIterator first, InputIterator last)*

Inserts the points in the range *[first, last)*. Returns the number of inserted points.

Precondition: The *value_type* of *InputIterator* is *Point*.

void *t.remove(Vertex_handle v)*

Removes the vertex from the triangulation. The created hole is re-triangulated.

Precondition: Vertex *v* must be finite.

Vertex_handle *t.move_if_no_collision(Vertex_handle v, Point p)*

if there is not already another vertex placed on *p*, the triangulation is modified such that the new position of vertex *v* is *p*, and *v* is returned. Otherwise, the triangulation is not modified and the vertex at point *p* is returned.

Precondition: Vertex *v* must be finite.

Vertex_handle *t.move(Vertex_handle v, Point p)*

same as above if there is no collision. Otherwise, *v* is deleted and the vertex placed on *p* is returned.

Precondition: Vertex *v* must be finite.

advanced

The following member functions offer more specialized versions of the insertion or removal operations to be used when one knows to be in the corresponding case.

Vertex_handle *t.insert_first(Point p)*

Inserts the first finite vertex .

Vertex_handle *t.insert_second(Point p)*

Inserts the second finite vertex .

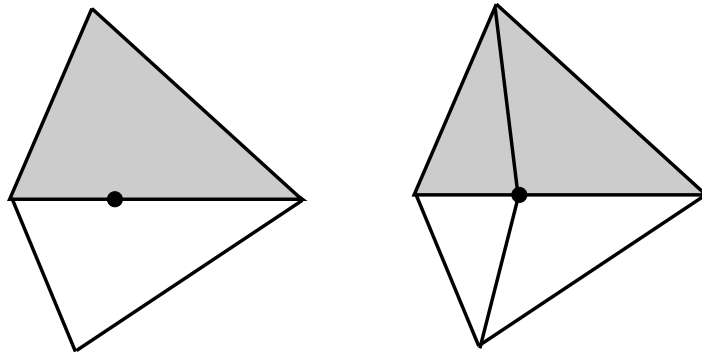

Figure 35.10: Insertion of a point on an edge.

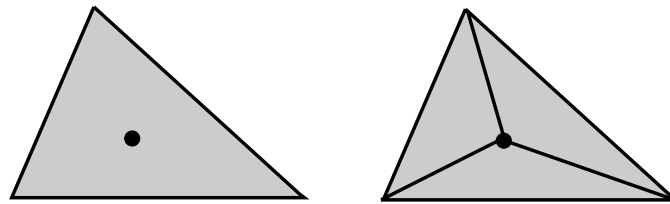

Figure 35.11: Insertion in a face.

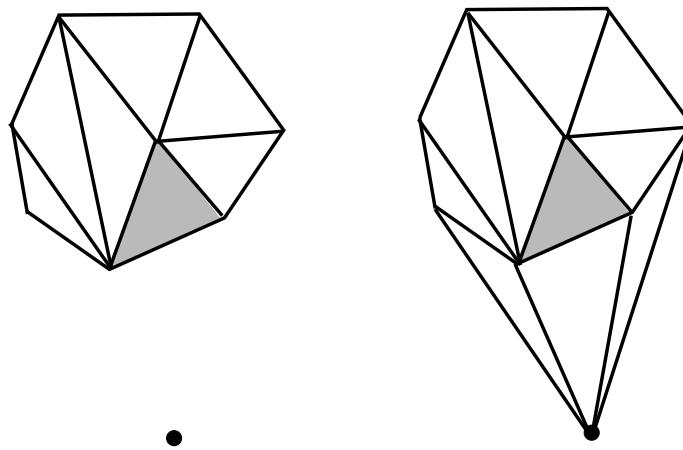

Figure 35.12: Insertion outside the convex hull.

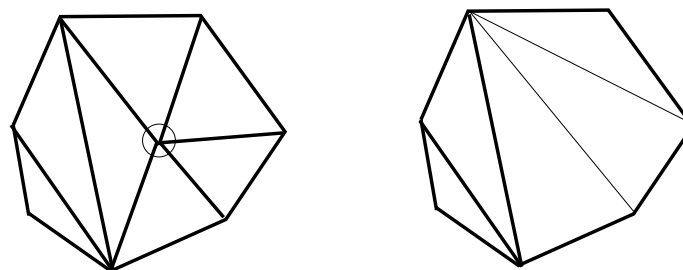

Figure 35.13: Removal

Vertex_handle *t.insert_in_face(Point p, Face_handle f)*

Inserts vertex v in face f . Face f is modified, two new faces are created.

Precondition: The point in vertex v lies inside face f .

Vertex_handle *t.insert_in_edge(Point p, Face_handle f, int i)*

Inserts vertex v in edge i of f .

Precondition: The point in vertex v lies on the edge opposite to the vertex i of face f .

Vertex_handle *t.insert_outside_convex_hull(Point p, Face_handle f)*

Inserts a point which is outside the convex hull but in the affine hull.

Precondition: The handle f points to a face which is a proof of the location of p , see the description of the *locate* method above.

Vertex_handle *t.insert_outside_affine_hull(Point p)*

Inserts a point which is outside the affine hull.

void *t.remove_degree_3(Vertex_handle v)*

Removes a vertex of degree three. Two of the incident faces are destroyed, the third one is modified.

Precondition: Vertex v is a finite vertex with degree three.

void *t.remove_second(Vertex_handle v)*

Removes the before last finite vertex.

void *t.remove_first(Vertex_handle v)*

Removes the last finite vertex.

The following functions are mainly intended to be used in conjunction with the *find_conflicts()* member functions of Delaunay and constrained Delaunay triangulations to perform insertions.

template<class EdgeIt>

Vertex_handle *t.star_hole(Point p, EdgeIt edge_begin, EdgeIt edge_end)*

creates a new vertex v and use it to star the hole whose boundary is described by the sequence of edges $[edge_begin, edge_end[$. Returns a handle to the new vertex.

template<class EdgeIt, class FaceIt>

```

Vertex_handle  t.star_hole( Point p,
                          EdgeIt edge_begin,
                          EdgeIt edge_end,
                          FaceIt face_begin,
                          FaceIt face_end)

```

same as above, except that the algorithm first recycles faces in the sequence *[face_begin, face_end[* and create new ones only when the sequence is exhausted.

_____ *advanced* _____

Traversal of the Triangulation

A triangulation can be seen as a container of faces and vertices. Therefore the triangulation provides several iterators and circulators that allow to traverse it (completely or partially).

Face, Edge and Vertex Iterators

The following iterators allow respectively to visit finite faces, finite edges and finite vertices of the triangulation. These iterators are non mutable, bidirectional and their value types are respectively *Face*, *Edge* and *Vertex*. They are all invalidated by any change in the triangulation.

<i>Finite_vertices_iterator</i>	<i>t.finite_vertices_begin()</i>	Starts at an arbitrary finite vertex
<i>Finite_vertices_iterator</i>	<i>t.finite_vertices_end()</i>	Past-the-end iterator
<i>Finite_edges_iterator</i>	<i>t.finite_edges_begin()</i>	Starts at an arbitrary finite edge
<i>Finite_edges_iterator</i>	<i>t.finite_edges_end()</i>	Past-the-end iterator
<i>Finite_faces_iterator</i>	<i>t.finite_faces_begin()</i>	Starts at an arbitrary finite face
<i>Finite_faces_iterator</i>	<i>t.finite_faces_end()</i>	Past-the-end iterator
<i>Point_iterator</i>	<i>t.points_begin()</i>	
<i>Point_iterator</i>	<i>t.points_end()</i>	Past-the-end iterator

The following iterators allow respectively to visit all (finite or infinite) faces, edges and vertices of the triangulation. These iterators are non mutable, bidirectional and their value types are respectively *Face*, *Edge* and *Vertex*. They are all invalidated by any change in the triangulation.

<i>All_vertices_iterator</i>	<i>t.all_vertices_begin()</i>	Starts at an arbitrary vertex
<i>All_vertices_iterator</i>	<i>t.all_vertices_end()</i>	Past-the-end iterator
<i>All_edges_iterator</i>	<i>t.all_edges_begin()</i>	Starts at an arbitrary edge
<i>All_edges_iterator</i>	<i>t.all_edges_end()</i>	Past-the-end iterator
<i>All_faces_iterator</i>	<i>t.all_faces_begin()</i>	Starts at an arbitrary face
<i>All_faces_iterator</i>	<i>t.all_faces_end()</i>	Past-the-end iterator

Line Face Circulator

The triangulation defines a circulator that allows to visit all faces that are intersected by a line. A face *f* is considered has being intersected by the oriented line *l* if either:

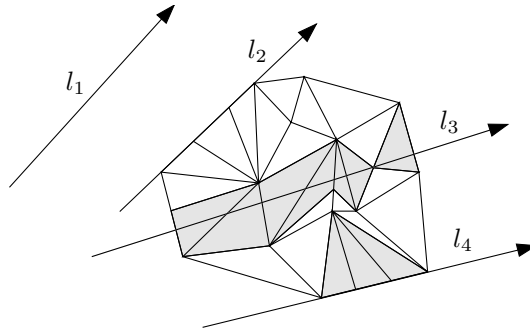

Figure 35.14: The line face circulator.

- f is a finite face whose interior intersects l , or
- f is a finite face with an edge collinear with l and lies to the left of l , or
- f is an infinite face incident to a convex hull edge whose interior is intersected by l , or
- f is an infinite face incident to a convex hull vertex lying on l and the finite edge of f lies to the left of l .

The circulator has a singular value if the line l intersect no finite face of the triangulation. This circulator is non-mutable and bidirectional. Its value type is *Face*.

Line_face_circulator $t.line_walk(Point\ p, Point\ q, Face_handle\ f = Face_handle())$

This function returns a circulator that allows to visit the faces intersected by the line pq . If there is no such face the circulator has a singular value.

The starting point of the circulator is the face f , or the first finite face traversed by l , if f is omitted.

The circulator wraps around the *infinite_vertex* : after the last traversed finite face, it steps through the infinite face adjacent to this face then through the infinite face adjacent to the first traversed finite face then through the first finite traversed face again.

Precondition: The triangulation must have dimension 2.

Precondition: Points p and q must be different points.

Precondition: If $f \neq NULL$, it must point to a finite face and the point p must be inside or on the boundary of f .

Figure 35.14 illustrates which finite faces are enumerated. Lines l_1 and l_2 have no face to their left. Lines l_3 and l_4 have faces to their left. Note that the finite faces that are only vertex incident to lines l_3 and l_4 are not enumerated.

A line face circulator is invalidated if the face the circulator refers to is changed.

Face, Edge and Vertex Circulators

The triangulation also provides circulators that allows to visit respectively all faces or edges incident to a given vertex or all vertices adjacent to a given vertex. These circulators are non-mutable and bidirectional. The *operator++* moves the circulator counterclockwise around the vertex while the *operator--* moves clockwise.

A face circulator is invalidated by any modification of the face pointed to. An edge or a vertex circulator are invalidated by any modification of one of the two faces incident to the edge pointed to.

Face_circulator *t.incident_faces(Vertex_handle v)*

Starts at an arbitrary face incident to *v*.

Face_circulator *t.incident_faces(Vertex_handle v, Face_handle f)*

Starts at face *f*.

Precondition: Face *f* is incident to vertex *v*.

Edge_circulator *t.incident_edges(Vertex_handle v)*

Starts at an arbitrary edge incident to *v*.

Edge_circulator *t.incident_edges(Vertex_handle v, Face_handle f)*

Starts at the first edge of *f* incident to *v*, in counterclockwise order around *v*.

Precondition: Face *f* is incident to vertex *v*.

Vertex_circulator *t.incident_vertices(Vertex_handle v)*

Starts at an arbitrary vertex incident to *v*.

Vertex_circulator *t.incident_vertices(Vertex_handle v, Face_handle f)*

Starts at the first vertex of *f* adjacent to *v* in counterclockwise order around *v*.

Precondition: Face *f* is incident to vertex *v*.

Traversal of the Convex Hull

Applied on the *infinite_vertex* the above functions allow to visit the vertices on the convex hull and the infinite edges and faces. Note that a counterclockwise traversal of the vertices adjacent to the *infinite_vertex* is a clockwise traversal of the convex hull.

Face_circulator *t.incident_faces(t.infinite_vertex())*

Face_circulator *t.incident_faces(t.infinite_vertex(), Face_handle f)*

Edge_circulator *t.incident_edges(t.infinite_vertex())*

Edge_circulator *t.incident_edges(t.infinite_vertex(), Face_handle f)*

Vertex_circulator *t.incident_vertices(t.infinite_vertex() v)*

Vertex_circulator *t.incident_vertices(t.infinite_vertex(), Face_handle f)*

Traversal between adjacent faces

Vertex_handle *t.mirror_vertex(Face_handle f, int i)*

returns the vertex of the i^{th} neighbor of *f* that is opposite to *f*.

Precondition: $0 \leq i \leq 2$.

int *t.mirror_index(Face_handle f, int i)*

returns the index of *f* in its i^{th} neighbor.

Precondition: $0 \leq i \leq 2$.

Miscellaneous

<i>int</i>	<i>t.ccw(int i)</i>	Returns $i + 1$ modulo 3. <i>Precondition:</i> $0 \leq i \leq 2$.
<i>int</i>	<i>t.cw(int i)</i>	Returns $i + 2$ modulo 3. <i>Precondition:</i> $0 \leq i \leq 2$.
<i>Triangle</i>		
	<i>t.triangle(Face_handle f)</i>	Returns the triangle formed by the three vertices of <i>f</i> . <i>Precondition:</i> The face is finite.
<i>Segment</i>	<i>t.segment(Face_handle f, int i)</i>	Returns the line segment formed by the vertices <i>ccw(i)</i> and <i>cw(i)</i> of face <i>f</i> . <i>Precondition:</i> $0 \leq i \leq 2$. The vertices <i>ccw(i)</i> and <i>cw(i)</i> of <i>f</i> are finite.
<i>Segment</i>	<i>t.segment(Edge e)</i>	Returns the line segment corresponding to edge <i>e</i> . <i>Precondition:</i> <i>e</i> is a finite edge
<i>Segment</i>	<i>t.segment(Edge_circulator ec)</i>	Returns the line segment corresponding to edge <i>*ec</i> . <i>Precondition:</i> <i>*ec</i> is a finite edge.
<i>Segment</i>	<i>t.segment(Edge_iterator ei)</i>	Returns the line segment corresponding to edge <i>*ei</i> . <i>Precondition:</i> <i>*ei</i> is a finite edge.
<i>Point</i>	<i>t.circumcenter(Face_handle f)</i>	Compute the circumcenter of the face pointed to by <i>f</i> . This function is available only if the corresponding function is provided in the geometric traits.

advanced

Setting

void *t.set_infinite_vertex(Vertex_handle v)*

Checking

The responsibility of keeping a valid triangulation belongs to the users if advanced operations are used. Obviously the advanced user, who implements higher levels operations may have to make a triangulation invalid at some times. The following method is provided to help the debugging.

bool *t.is_valid(bool verbose = false, int level = 0)*

Checks the combinatorial validity of the triangulation and also the validity of its geometric embedding. This method is mainly a debugging help for the users of advanced features.

advanced

I/O

The I/O operators are defined for *iostream*. The format for the *iostream* is an internal format.

ostream& *ostream& os << T*

Inserts the triangulation *t* into the stream *os*.
Precondition: The insert operator must be defined for *Point*.

istream& *istream*& *is* >> *T* Reads a triangulation from stream *is* and assigns it to *t*.
Precondition: The extract operator must be defined for *Point*.

The information output in the *iostream* is:

- the number of vertices (including the infinite one), the number of faces (including infinite ones), and the dimension.
- for each vertex (except the infinite vertex), the non combinatorial information stored in that vertex (point, etc.).
- for each faces, the indices of its vertices and the non combinatorial information (if any) in this face.
- for each face again the indices of the neighboring faces.

The index of an item (vertex or face) is the rank of this item in the output order. When dimension < 2, the same information is output for faces of maximal dimension instead of faces.

CGAL also provides a stream operator << to draw triangulations for *CGAL::Qt_widget*, the Qt based graphic package. These operators require the include statement :

```
#include CGAL/IO/Qt_widget_Triangulation_2.h
```

See the *Qt_widget* class.

Implementation

Locate is implemented by a line walk from a vertex of the face given as optional parameter (or from a finite vertex of *infinite_face()* if no optional parameter is given). It takes time $O(n)$ in the worst case, but only $O(\sqrt{n})$ on average if the vertices are distributed uniformly at random.

Insertion of a point is done by locating a face that contains the point, and then splitting this face. If the point falls outside the convex hull, the triangulation is restored by flips. Apart from the location, insertion takes a time $O(1)$. This bound is only an amortized bound for points located outside the convex hull.

Removal of a vertex is done by removing all adjacent triangles, and re-triangulating the hole. Removal takes time $O(d^2)$ in the worst case, if d is the degree of the removed vertex, which is $O(1)$ for a random vertex.

The face, edge, and vertex iterators on finite features are derived from their counterparts visiting all (finite and infinite) features which are themselves derived from the corresponding iterators of the triangulation data structure.

CGAL::Triangulation_cw_ccw_2

Definition

The class *Triangulation_cw_ccw_2* offer two functions *int cw(int i)* and *int ccw(int i)* which given the index of a vertex in a face compute the index of the next vertex of the same face in clockwise or counterclockwise order. This works also for neighbor indexes. Thus, for example the neighbor *neighbor(cw(i))* of a face *f* is the neighbor which is next to *neighbor(i)* turning clockwise around *f*. The face *neighbor(cw(i))* is also the first face encountered after *f* when turning clockwise around vertex *i* of *f*.

Many of the classes in the triangulation package inherit from *Triangulation_cw_ccw_2*. This is for instance the case for *CGAL::Triangulation_2<Traits,Tds>::Face*. Thus, for example the neighbor *neighbor(cw(i))* of a face *f* is the neighbor which is next to *neighbor(i)* turning clockwise around *f*. The face *neighbor(cw(i))* is also the first face encountered after *f* when turning clockwise around vertex *i* of *f*.

```
#include <CGAL/Triangulation_2.h>
```

Creation

Triangulation_cw_ccw_2 a; default constructor.

Operations

<i>int</i>	<i>a.ccw(const int i)</i>	returns the index of the neighbor or vertex that is next to the neighbor or vertex with index <i>i</i> in counterclockwise order around a face.
<i>int</i>	<i>a.cw(const int i)</i>	returns the index of the neighbor or vertex that is next to the neighbor or vertex with index <i>i</i> in clockwise order around a face.

CGAL::Triangulation_euclidean_traits_xy_3<*K*>

CGAL::Triangulation_euclidean_traits_xy_3<K>

Definition

The class *Triangulation_euclidean_traits_xy_3<K>* is a geometric traits class which allows to triangulate a terrain. This traits class is designed to build a two dimensional triangulation embedded in 3D space, i.e. a triangulated surface, such that its on the *xy* plane is a Delaunay triangulation. This is a usual construction for GIS terrains. Instead of really projecting the 3D points and maintaining a mapping between each point and its projection (which costs space and is error prone) the class *Triangulation_euclidean_traits_xy_3<K>* supplies geometric predicates that ignore the *z*-coordinate of the points.

The class is a model of the concept *DelaunayTriangulationTraits_2* except that it does not provide the type and constructors required to build the dual Voronoi diagram. The class is also a model of the concept *ConstrainedTriangulationTraits_2*.

Parameters

The template parameter *K* has to be instantiated by a model of the *Kernel* concept. *Triangulation_euclidean_traits_xy_3<K>* uses types and predicates defined in *K*.

```
#include <CGAL/Triangulation_euclidean_traits_xy_3.h>
```

Types

```
typedef Point_3<K>      Point_2;
typedef Segment_3<K>    Segment_2;

typedef Triangle_3<K>    Triangle_2;

typedef Line_3<K>        Line_2;
```

The following predicates and constructor types are provided

Triangulation_euclidean_traits_xy_3<K>::Construct_segment_2

A constructor object for *Segment_2*. Provides :
Segment_2 operator()(Point_2 p, Point_2 q),
 which constructs a segment from two points.

Triangulation_euclidean_traits_xy_3<K>::Construct_triangle_2

A constructor object for *Triangle_2*. Provides :
Triangle_2 operator()(Point_2 p, Point_2 q, Point_2 r),
 which constructs a triangle from three points.

Triangulation_euclidean_traits_xy_3<K>::Construct_line_2

A constructor object for *Line_2*. Provides :
Line_2 operator()(Point_2 p, Point_2 q),
 which constructs a line from two points.

Triangulation_euclidean_traits_xy_3<K>:: Compute_squared_distance_2

A construction object. Provides the operator :
RT operator()(Line_2 l, Point_2 p); which returns the squared distance between the projection of *p* and the projection of *l*.

Triangulation_euclidean_traits_xy_3<K>:: Intersect_2

A construction object. Provides the operator :
Object_2 operator()(Segment_2 s1, Segment_2 s2); which returns the intersection of the projection of *s1* and the projection of *s2* embedded in 3D. If the intersection is a segment, the *z*-coordinates of its extremities is 0. If the intersection is a point *p*, let *p1* and *p2* be the points on *s1* and *s2* respectively, such that their projections are *p*. The point returned is the middle of the segment *p1p2*.
Precondition: The projection of *s1* and the projection of *s2* are non-degenerate 2D segments.

Triangulation_euclidean_traits_xy_3<K>:: Compare_x_2

Predicate object. Provides the operator :
Comparison_result operator()(Point_2 p, Point_2 q)
which returns *SMALLER*, *EQUAL* or *LARGER* according to the *x*-ordering of points *p* and *q*.

Triangulation_euclidean_traits_xy_3<K>:: Compare_y_2

Predicate object. Provides the operator :
Comparison_result operator()(Point_2 p, Point_2 q)
which returns (*SMALLER*, *EQUAL* or *LARGER*) according to the *y*-ordering of points *p* and *q*.

Triangulation_euclidean_traits_xy_3<K>:: Orientation_2

Predicate object. Provides the operator :
Orientation operator()(Point_2 p, Point_2 q, Point_2 r)
which returns *LEFT_TURN*, *RIGHT_TURN* or *COLLINEAR* according to the position of the projection of *r* with respect to the projection of the oriented line *pq*.

Triangulation_euclidean_traits_xy_3<K>:: Side_of_oriented_circle_2

Predicate object. Provides the operator : *Oriented_side operator()(Point_2 p, Point_2 q, Point_2 r, Point_2 s)* which takes four points *p, q, r, s* as arguments and returns *ON_POSITIVE_SIDE*, *ON_NEGATIVE_SIDE* or *ON_ORIENTED_BOUNDARY* according to the position of the projection of points with respect to the oriented circle through the projections of *p, q* and *r*.

Triangulation_euclidean_traits_xy_3<K>:: Compare_distance_2

Predicate object. Provides the operator :
Comparison_result operator()(Point_2 p, Point_2 q, Point_2 r) which returns *SMALLER*, *EQUAL* or *LARGER* according to the distance between the projection of *p* and the projection of *q* being smaller, equal or larger than the distance between the projection of *p* and the projection of *r*.

Creation

Only a default constructor, copy constructor and an assignment operator are required. Note that further constructors can be provided.

Triangulation_euclidean_traits_xy_3<K> traits;

default constructor.

Triangulation_euclidean_traits_xy_3<K> traits(*Triangulation_euclidean_traits_xy_3* tr);

Copy constructor.

Triangulation_euclidean_traits_xy_3 traits = *Triangulation_euclidean_traits_xy_3* tr

Assignment operator.

Access to predicate objects

The following access functions are provided

<i>Construct_segment_2</i>	<i>traits.construct_segment_2_object()</i>
<i>Construct_triangle_2</i>	<i>traits.construct_triangle_2_object()</i>
<i>Construct_line_2</i>	<i>traits.construct_line_2_object()</i>
<i>Comparison_x_2</i>	<i>traits.compare_x_2_object()</i>
<i>Comparison_y_2</i>	<i>traits.compare_y_2_object()</i>
<i>Orientation_2</i>	<i>traits.orientation_2_object()</i>
<i>Side_of_oriented_circle_2</i>	<i>traits.side_of_oriented_circle_2_object()</i>
<i>Compare_distance_2</i>	<i>traits.compare_distance_2_object()</i>
<i>Intersect_2</i>	<i>traits.intersect_2_object()</i>
<i>Compute_squared_distance_2</i>

`#include <CGAL/Triangulation_euclidean_traits_yz_3.h>`

CGAL::Triangulation_face_base_2<Traits,Fb>

Definition

The class *Triangulation_face_base_2<Traits,Fb>* is a model for the concept *TriangulationFaceBase_2*. It is the default face base class for basic and Delaunay triangulation.

These default base class can be used directly or can serve as a base to derive other base classes with some additional attribute (a color for example) tuned for specific applications.

Parameters

The first template parameter of *Triangulation_face_base_2<Traits,Fb>* is a geometric traits class. The geometric traits is actually not used by the class.

The second template parameter has to be a model of the concept *TriangulationDSFaceBase_2* and will serve as a base class for *Triangulation_face_base_2<Traits,Fb>*. CGAL provides a default instantiation for this parameter which is *Triangulation_ds_face_base_2<>*.

CGAL::Triangulation_face_base_with_info_2<Info,Traits,Fb>

Definition

The class *Triangulation_face_base_with_info_2<Info,Traits,Fb>* is a model of the concept *TriangulationFaceBase_2* to be plugged into the triangulation data structure of a triangulation class. It provides an easy way to add some user defined information in the faces of a triangulation.

```
#include <CGAL/Triangulation_face_base_with_info_2.h>
```

Parameters

The first template argument is the information the user would like to add to a face. It has to be *DefaultConstructible* and *Assignable*.

The second template argument is a geometric traits class and is actually not used in *Triangulation_face_base_with_info_2<Info,Traits,Fb>* .

The third parameter is a face base class from which *Triangulation_face_base_with_info_2<Info,Traits,Fb>* derives.

Inherits From

Fb

Is Model for the Concepts

Because *Triangulation_face_base_with_info_2<Info,Traits,Fb>* derives from the class instantiating its third parameter, it will be a model of the same face base concept as its parameter : *TriangulationFaceBase_2*, *ConstrainedTriangulationFaceBase_2* , or *RegularTriangulationFaceBase_2*

Types

```
typedef Info          Info;
```

Access Functions

<i>const Info&</i>	<i>f.info() const</i>	Returns a const reference to the object of type <i>Info</i> stored in the face.
<i>Info&</i>	<i>f.info()</i>	Returns a reference to the object of type <i>Info</i> stored in the face.

CGAL::Triangulation_hierarchy_2<Tr>

Definition

The class *Triangulation_hierarchy_2<Tr>* implements a triangulation augmented with a data structure which allows fast point location queries.

The data structure is a hierarchy of triangulations. The triangulation at the lowest level is the original triangulation where operations and point location are to be performed. Then at each succeeding level, the data structure stores a triangulation of a small random sample of the vertices of the triangulation at the preceding level.

Point location is done through a top-down nearest neighbor query. The nearest neighbor query is first performed naively in the top level triangulation. Then, at each following level, the nearest neighbor at that level is found through a linear walk performed from the nearest neighbor found at the preceding level.

Because the number of vertices in each triangulation is only a small fraction of the number of vertices of the preceding triangulation the data structure remains small and achieves fast point location queries on real data. As proved in [Dev98], this structure has an optimal behavior when it is built for Delaunay triangulations. However it can be used as well for other triangulations. The class *Triangulation_hierarchy_2<Tr>* is templated by a parameter which is to be instantiated by anyone of the CGAL triangulation classes.

```
#include <CGAL/Triangulation_hierarchy_2.h>
```

Inherits From

Tr

Types

The class *Triangulation_hierarchy_2<Tr>* inherits the types from its base triangulation class *Tr*.

The class *Triangulation_hierarchy_2<Tr>* offers exactly the same functionalities as the triangulation *Tr* does. Location queries are overloaded to benefit from the data structure. Modifiers (insertion, removal, and displacement) are overloaded to take care of updating the data structure.

Be careful that I/O operations are not overloaded. Writing a *Triangulation_hierarchy_2<Tr>* into a file writes only the lowest level triangulation and drop the hierarchy and reading it from a file results in a triangulation whose efficiency will be that of an ordinary triangulation.

36.1 Definition

A triangulation data structure is a data structure designed to handle the representation of a two dimensional triangulation. The concept of triangulation data structure was primarily designed to serve as a data structure for CGAL 2D triangulation classes which are triangulations embedded in a plane. However it appears that the concept is more general and can be used for any orientable triangulated surface without boundary, whatever may be the dimensionality of the space the triangulation is embedded in.

36.1.1 A Data Structure Based on Faces and Vertices

The representation of CGAL 2D triangulations is based on faces and vertices, Edges are only implicitly represented through the adjacency relations between two faces.

The triangulation data structure can be seen as a container for faces and vertices maintaining incidence and adjacency relations among them.

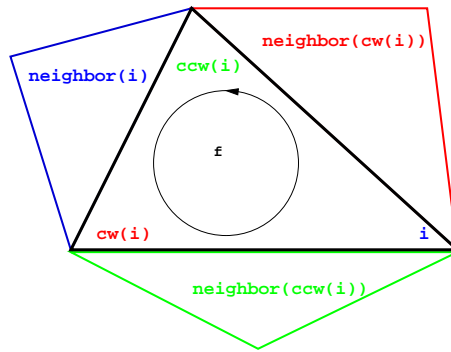

Figure 36.1: Vertices and neighbors.

Each triangular face gives access to its three incident vertices and to its three adjacent faces. Each vertex gives access to one of its incident faces and through that face to the circular list of its incident faces.

The three vertices of a face are indexed with 0, 1 and 2. The neighbors of a face are also indexed with 0,1,2 in such a way that the neighbor indexed by i is opposite to the vertex with the same index. See Figure 36.1, the functions $ccw(i)$ and $cw(i)$ shown on this figure compute respectively $i + 1$ and $i - 1$ modulo 3

Each edge has two implicit representations: the edge of a face f which is opposed to the vertex indexed i , can be represented as well as an edge of the $neighbor(i)$ of f .

This kind of representation of simplicial complexes extends in any dimension. More precisely, in dimension d , the data structure will explicitly represents cells (i. e. faces of maximal dimension) and vertices (i. e. faces of dimension 0). All faces of dimension between 1 and $d - 1$ will have an implicit representation. The 2D triangulation data structure can represent simplicial complexes of dimension 2, 1 or 0.

36.1.2 The Set of Faces and Vertices

The set of faces maintained by a 2D triangulation data structure is such that each edge is incident to two faces. In other words, the set of maintained faces is topologically equivalent to a two-dimensional triangulated sphere.

This rules extends to lower dimensional triangulation data structure arising in degenerate cases or when the triangulations have less than three vertices. A one dimensional triangulation structure maintains a set of vertices and edges which forms a ring topologically equivalent to a 1-sphere.

A zero dimensional triangulation data structure only includes two adjacent vertices that is topologically equivalent to a 0-sphere.

36.2 The Concept of Triangulation Data Structure

A model of *TriangulationDataStructure_2* can be seen has a container for the faces and vertices of the triangulation. This class is also responsible for the combinatorial integrity of the triangulation. This means that the triangulation data structure maintains proper incidence and adjacency relations among the vertices and faces of a triangulation while combinatorial modifications of the triangulation are performed. The term combinatorial modification refers to operations which do not involve any knowledge about the geometric embedding of the triangulation. For example, the insertion of a new vertex in a given face, or in a given edge, the suppression

Figure 36.2: Insertion of a new vertex, splitting a face

of a vertex of degree three, the flip of two edge are examples of combinatorial operation performed at the data structure level.

The triangulation data structure is required to provide:

- the types *Vertex* and *Face* for the vertices and faces of the triangulations
- the type *Vertex_handle* and *Face_handle* which are models of the concept *Handle* and through which the vertices and faces are accessed.
- iterators to visit all the vertices, edges and faces of the triangulation,
- circulators to visit all the vertices, edges and faces incident to a given vertex

The triangulation data structure is responsible for the creation and removal of faces and vertices (memory management). It provides function that gives the number of faces, edges and vertices of the triangulation.

The triangulation data structure provides member functions to perform the following combinatorial transformation of the triangulation:

- flip of two adjacent faces,
- addition of a new vertex splitting a given face see Figure 36.2,
- addition of a new vertex splitting a given edge,
- addition of a new vertex raising by one the dimension of a degenerate – lower dimensional triangulation,
- removal of a vertex incident to three faces,
- removal of a vertex lowering the dimension of the triangulation

36.3 The Default Triangulation Data Structure

CGAL provides the class `CGAL::Triangulation_data_structure_2<Vb,Fb>` as a default triangulation data structure.

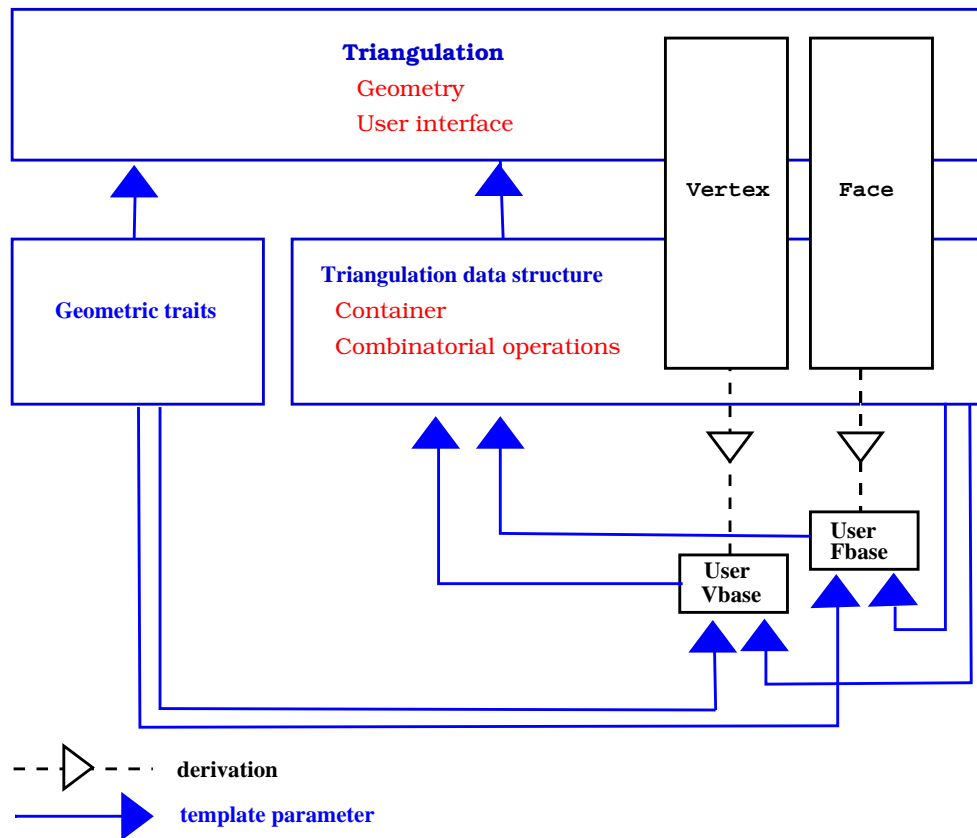

Figure 36.3: The cyclic dependency in triangulations software design.

36.3.1 Flexibility

In order to provide flexibility, the default triangulation data structure is templated by two parameters which stands respectively for a vertex base class and a face base class. The concept *TriangulationDSVertexBase_2* and *TriangulationDSFaceBase_2* describe the requirements for the vertex and face classes of a triangulation data structure.

This design allows the user to plug in the triangulation data structure his own vertex or face classes tuned for his application.

36.3.2 The Cyclic Dependency of Template Parameters

Since adjacency and incidence relation are stored in vertices and faces, the vertex and face classes have to know the types of handles on faces and vertices provided by the triangulation data structure. Therefore, vertex and face classes need to be templated by the triangulation data structure. Because the triangulation data structure is itself templated by the vertex and face classes this induces a cyclic dependency. See figure 36.3.

36.3.3 The Rebind Mechanism

The solution proposed by CGAL to resolve this cyclic dependency is based on a rebind mechanism similar to the mechanism used in the standard allocator class `std::allocator`. The vertex and face classes plugged in the instantiation of a triangulation data structure are themselves instantiated with a fake data structure. The triangulation data structure will then rebind these classes, plugging itself at the place of the fake data structure, before using them to derive the vertex and face classes. The rebinding is performed through a nested template class *Rebind_TDS* in the vertex and face class, which provide the rebound class as a type called *Other*.

Here is how it works schematically. First, here is the rebinding taking place in the triangulation data structure.

```
template < class Vb, class Fb >
class Triangulation_data_structure
{
    typedef Triangulation_data_structure<Vb,Fb>    Self;

    // Rebind the vertex and face base to the actual TDS (Self).
    typedef typename Vb::template Rebind_TDS<Self>::Other    VertexBase;
    typedef typename Fb::template Rebind_TDS<Self>::Other    FaceBase;

    // ... further internal machinery leads to the final public types:
public:
    typedef ...    Vertex;
    typedef ...    Face;
    typedef ...    Vertex_handle;
    typedef ...    Face_handle;
};
```

Then, here is the vertex class with its nested *Rebind_TDS* template class and its template parameter set by default to an internal type faking a triangulation data structure.

```
template < class TDS = an internal type faking a triangulation data
structure >
class Vertex_base
{
public:
    template < class TDS2 >
    struct Rebind_TDS {
        typedef Vertex_base<TDS2>    Other;
    };
    ...
};
```

Imagine an analog *Face_base* class. The triangulation data structure is then instantiated as follows :

```
typedef Triangulation_data_structure< Vertex_base<>, Face_base<> > TDS;
```

36.3.4 Making Use of the Flexibility

There is several possibilities to make use of the flexibility offered by the triangulation data structure.

- First, when the user needs to have, in vertices and faces, additional information which do not depend on types defined by the triangulated data structure, predefined classes *Triangulation_vertex_base_with_info* and *Triangulation_face_base_with_info* can be plugged in. Those classes have a template parameter *Info* to be instantiated by a user defined type. They store a data member of this type and gives access to it.
- Second, the user can derive his own base classes from the default base classes: *Triangulation_ds_vertex_base_2*, and *Triangulation_ds_face_base_2* are the default base classes to be plugged in a triangulation data structure used alone. Triangulation classes requires a data structure in which other base classes have been plugged it. The default base classes for most of the triangulation classes are *Triangulation_vertex_base_2*, and *Triangulation_face_base_2* are the default base classes to be used when the triangulation data structure is plugged in a triangulation class.

When derivation is used, the rebinding mechanism is slightly more involved, because it is necessary to rebinding the base class itself. However the user will be able to use in his classes references to types provided by the triangulation data structure. For example,

```
template < class Gt, class Vb = CGAL::Triangulation_vertex_base_2<Gt>
>
class My_vertex_base
: public Vb
{
public :
    template < typename TDS2 >
    struct Rebind_TDS {
        typedef typename Vb::template Rebind_TDS<TDS2>::Other    Vb2;
        typedef My_vertex_base<Gt,Vb2>                          Other;
    };

    typedef typename Vb::Triangulation_data_structure            Tds;
    typedef typename Tds::Vertex_handle                         Vertex_handle;
    .....
};
```

- At last the user can write his own base classes. If the triangulation data structure is used alone, the requirements for the base classes are described by the concepts *TriangulationDSVertexBase_2* and *TriangulationDSFaceBase_2*, documented page 2432 and page 2427. If the triangulation data structure is plugged into a triangulation class, the concepts for the vertex and base classes depends on the triangulation class. The most basic concepts, valid for basic and Delaunay triangulations are *TriangulationVertexBase_2* and *TriangulationFaceBase_2*, documented page 2381 and page 2376.

See section 35.11 for examples of using the triangulation data structure flexibility.

2D Triangulation Data Structure Reference Manual

Sylvain Pion and Mariette Yvinec

The triangulation data structure can be seen as a container for the faces and vertices of a triangulation. This class also takes care of all the combinatorial operations performed on the triangulation.

The class `CGAL::Triangulation_data_structure_2<Vb,Fb>` is a model of the concept `TriangulationDataStructure_2`, which includes the sub-concepts `TriangulationDataStructure_2::Face` and `TriangulationDataStructure_2::Vertex`.

To ensure all the **flexibility** of the triangulation classes, described and in Section 35.11 of Chapter 35, the model `CGAL::Triangulation_data_structure_2<Vb,Fb>` has two templates parameters. The class `CGAL::Triangulation_data_structure_2<Vb,Fb>` derives its `Vertex` and `Face` types from the two template parameters `Vb` and `Fb` respectively.

If the triangulation data structure is used alone, these parameters have to be instantiated by models of the concepts `TriangulationDSFaceBase_2` and `TriangulationDSVertexBase_2`. These concepts are described in this chapter together with their default models `CGAL::Triangulation_ds_face_base_2<Tds>` and `CGAL::Triangulation_ds_vertex_base_2<Tds>`.

If the triangulation data structure is plugged into a triangulation class, the parameters have to be instantiated by models of different refining concepts according to the actual type of the triangulation. These refining concepts and their models are described in Chapter 35.12

TriangulationDataStructure_2

Definition

The concept `TriangulationDataStructure_2` describes the requirements for the second template parameter of the basic triangulation class `Triangulation_2<Traits,Tds>` and of all other 2D triangulation classes.

The concept can be seen as a container for the faces and vertices of the triangulation. The concept `TriangulationDataStructure_2` includes two sub-concepts `TriangulationDataStructure_2::Vertex` and `TriangulationDataStructure_2::Face`, described respectively page [2434](#) and page [2430](#).

The `TriangulationDataStructure_2` maintains incidence and adjacency relations among vertices and faces.

Each triangular face gives access to its three incident vertices and to its three adjacent faces. Each vertex gives access to one of its incident faces and through that face to the circular list of its incident faces.

The three vertices of a face are indexed with 0, 1 and 2. The neighbors of a face are also indexed with 0,1,2 in such a way that the neighbor indexed by i is opposite to the vertex with the same index.

Each edge has two implicit representations : the edge of a face f which is opposed to the vertex indexed i , can be represented as well as an edge of the $neighbor(i)$ of f . See Figure [35.2](#)

The triangulation data structure is responsible for the combinatorial integrity of the triangulation. This means that the triangulation data structure allows to perform some combinatorial operations on the triangulation and guarantees the maintenance on proper incidence and adjacency relations among the vertices and faces. The term combinatorial operations means that those operations are purely topological and do not depend on the geometric embedding. Insertion of a new vertex in a given face, or in a given edge, suppression of a vertex of degree three, flip of two edges are examples of combinatorial operations.

Types

<code>TriangulationDataStructure_2::size_type</code>	Size type (unsigned integral type)
<code>TriangulationDataStructure_2::difference_type</code>	Difference type (signed integral type)
<code>TriangulationDataStructure_2::Vertex</code>	The vertex type. Requirements for this type are described in concept <code>TriangulationDataStructure_2::Vertex</code> page 2434 .
<code>TriangulationDataStructure_2::Face</code>	The face type. Requirements for this type are described in concept <code>TriangulationDataStructure_2::Face</code> page 2430 .

Vertices and faces are accessed via `Vertex_handle` and `Face_handle`. These types are models of the concept `Handles` which basically supports the two dereference operators `*` and `->`.

<code>TriangulationDataStructure_2::Vertex_handle</code>	Handle to a vertex
<code>TriangulationDataStructure_2::Face_handle</code>	Handle to a face.
<code>typedef std::pair<Face_handle,int> Edge;</code>	The edge type. The <code>Edge(f,i)</code> is edge common to faces f and $f.neighbor(i)$. It is also the edge joining the vertices $vertex(cw(i))$ and $vertex(ccw(i))$ of f .

The following iterators allow one to visit all the vertices, edges and faces of a triangulation data structure. They are all bidirectional, non-mutable iterators.

TriangulationDataStructure_2:: Face_iterator
TriangulationDataStructure_2:: Edge_iterator
TriangulationDataStructure_2:: Vertex_iterator

The following circulators allow to visit all the edges or faces incident to a given vertex and all the vertices adjacent to a given vertex. They are all bidirectional and non mutable.

TriangulationDataStructure_2:: Face_circulator
TriangulationDataStructure_2:: Edge_circulator
TriangulationDataStructure_2:: Vertex_circulator

Iterators and circulators are convertible to the corresponding handles, thus they can be passed directly as argument to the functions expecting a handle.

Creation

TriangulationDataStructure_2 tds; default constructor.

TriangulationDataStructure_2 tds(tds1); Copy constructor. All the vertices and faces are duplicated.

TriangulationDataStructure_2& tds = tds1

Assignment. All the vertices and faces of *tds1* are duplicated in *tds* . Former faces and vertices of *tds* , if any, are deleted

Vertex_handle tds.copy_tds(tds1, Vertex_handle v = Vertex_handle())

tds1 is copied into *tds*. If *v* != *NULL*, the vertex of *tds* corresponding to *v* is returned, otherwise *Vertex_handle()* is returned.

Precondition: The optional argument *v* is a vertex of *tds1*.

void tds.swap(& tds1) Swaps *tds* and *tds1*. Should be preferred to *tds=tds1* or *tds(tds1)* when *tds1* is deleted after that.

void tds.clear() Deletes all faces and all finite vertices.

Access Functions

int tds.dimension() returns the dimension of the triangulation.
size_type

size_type tds.number_of_vertices() returns the number of vertices in the data structure.

tds.number_of_faces() returns the number of two dimensional faces in the data structure.

size_type

tds.number_of_edges()

returns the number of edges in the triangulation data structure.

size_type

tds.number_of_full_dim_faces()

returns the number of full dimensional faces, i.e. faces of dimension equal to the dimension of the triangulation. This is the actual number of faces stored in the triangulation data structure.

————— *advanced* —————

Setting

void tds.set_dimension(int n)

sets the dimension.

————— *advanced* —————

Queries

bool tds.is_vertex(Vertex_handle v)

returns true if *v* is a vertex of *tds*.

bool tds.is_edge(Face_handle fh, int i)

tests whether *(fh,i)* is an edge of *tds*. Answers *false* when *dimension() < 1*.

bool tds.is_edge(Vertex_handle va, Vertex_handle vb)

returns true if *va vb* is an edge of *tds*.

bool tds.is_edge(Vertex_handle va, Vertex_handle vb, Face_handle &fr, int &i)

as previous. In addition, if true is returned *fr* and *i* are set such that the pair *(fr,i)* is the description of the ordered edge *va vb*.

bool tds.is_face(Face_handle fh)

tests whether *fh* is a face of *tds*. Answers *false* when *dimension() < 2*.

bool tds.is_face(Vertex_handle v1, Vertex_handle v2, Vertex_handle v3)

true if there is a face having *v1*, *v2* and *v3* as vertices.

bool tds.is_face(Vertex_handle v1, Vertex_handle v2, Vertex_handle v3, Face_handle &fr)

as above. In addition, if *true* is returned, *fr* is a pointer to the face with *v1*, *v2* and *v3* as vertices.

Traversing the triangulation

Face_iterator tds.faces_begin()

visits all faces

Face_iterator tds.faces_end()

Vertex_iterator tds.vertices_begin()

visits all vertices

Vertex_iterator tds.vertices_end()

<i>Edge_iterator</i>	<i>tds.edges_begin()</i>	visits all edges
<i>Edge_iterator</i>	<i>tds.edges_end()</i>	

Three circulator classes allow to traverse the edges or faces incident to a vertex or the vertices adjacent to this vertex.. A face circulator is invalidated by any modification of the face it points to. An edge circulator is invalidated by any modification of anyone of the two faces incident to the edge pointed to. A vertex circulator that turns around vertex v and that has as value a pointer to vertex w , is invalidated by any modification of anyone of the two faces incident to v and w .

<i>Vertex_circulator</i>	<i>tds.incident_vertices(Vertex_handle v, Face_handle f=NULL)</i>
--------------------------	--

Precondition: If the face f is given, it has to be incident to be a face of tds incident to v and the circulator begins with the vertex $f->vertex(ccw(i))$ if i is the index of v in f .

<i>Edge_circulator</i>	<i>tds.incident_edges(Vertex_handle v, Face_handle f=NULL)</i>
------------------------	---

Precondition: If the face f is given, it has to be a face of tds incident to v and the circulator begins with the edge $(f,cw(i))$ of f if i is the index of v in f .

<i>Face_circulator</i>	<i>tds.incident_faces(Vertex_handle v, Face_handle f=NULL)</i>
------------------------	---

Precondition: If the face f is given, it has to be a face of tds incident to v and the circulator begins with the face f .

<i>Vertex_handle</i>	<i>tds.mirror_vertex(Face_handle f, int i)</i>
----------------------	---

returns vertex of $f->neighbor(i)$.

<i>int</i>	<i>tds.mirror_index(Face_handle f, int i)</i>
------------	--

returns the index of f as a neighbor of $f->neighbor(i)$.

Modifiers

The following modifier member functions guarantee the combinatorial validity of the resulting triangulation.

<i>void</i>	<i>tds.flip(Face_handle f, int i)</i>	exchanges the edge incident to f and $f->neighbor(i)$ with the other diagonal of the quadrilateral formed by f and $f->neighbor(i)$.
-------------	--	---

<i>Vertex_handle</i>	<i>tds.insert_first()</i>	creates the first vertex and returns a pointer to it.
<i>Vertex_handle</i>	<i>tds.insert_second()</i>	creates the second vertex and returns a pointer to it.

<i>Vertex_handle</i>	<i>tds.insert_in_edge(Face_handle f, int i)</i>	adds a vertex v splitting edge i of face f . Return a pointer to v .
----------------------	--	--

<i>Vertex_handle</i>	<i>tds.insert_in_face(Face_handle f)</i>	adds a vertex v splitting face f in three. Face f is modified, two new faces are created. Return a pointer to v
----------------------	---	---

Figure 36.4: Flip.

Figure 36.5: Insertion

Vertex_handle *tds.insert_dim_up(Vertex_handle w, bool orient=true)*

adds a vertex *v*, increasing by one the dimension of the triangulation. Vertex *v* and the existing vertex *w* are linked to all the vertices of the triangulation. The Boolean *orient* decides the final orientation of all faces. A pointer to vertex *v* is returned.

void *tds.remove_degree_3(Vertex_handle v, Face *f=NULL)*

removes a vertex of degree 3. Two of the incident faces are destroyed, the third one is modified. If parameter *f* is specified, it has to be a face incident to *v* and will be the modified face.

Precondition: Vertex *v* is a finite vertex with degree 3 and, if specified, face *f* is incident to *v*.

void *tds.remove_second(Vertex_handle v)*

removes the before last vertex.

void *tds.remove_first(Vertex_handle v)*

removes the last vertex.

void *tds.remove_dim_down(Vertex_handle v)*

removes vertex *v* incident to all other vertices and decreases by one the dimension of the triangulation.

Precondition: if the dimension is 2, the number of vertices is more than 3, if the dimension is 1, the number of vertices is 2.

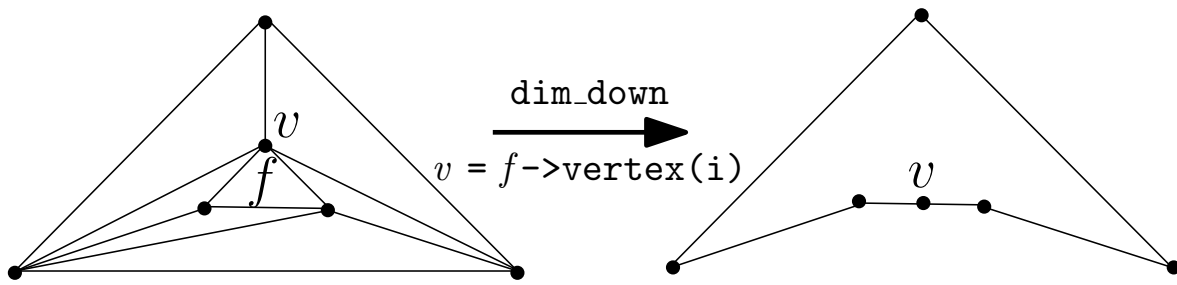

Figure 36.6: From a two-dimensional data structure to a one-dimensional data structure.

The following operation, `dim_down`, is necessary when the displacement of a vertex decreases the dimension of the triangulation.

```
void tds.dim_down( Face_handle f, int i)
```

The link of a vertex v is formed by the edges disjoint from v that are included in the faces incident to v . When the link of $v = f \rightarrow \text{vertex}(i)$ contains all the other vertices of the two-dimensional triangulation data-structure (\mathbb{S}^2), `dim_down` crushes the two-dimensional data-structure (\mathbb{S}^2) onto the one-dimensional data structure (\mathbb{S}^1) formed by the link of v augmented with the vertex v itself; this one is placed on the edge (f, i) . (see Fig. 36.6).

Precondition: `dimension()` must be equal to 2, the degree of $f \rightarrow \text{vertex}(i)$ must be equal to the total number of vertices minus 1.

advanced

The following modifiers are required for convenience of the advanced user. They do not guarantee the combinatorial validity of the resulting triangulation.

```
template< class EdgeIt>
Vertex_handle tds.star_hole( EdgeIt edge_begin, EdgeIt edge_end)
```

creates a new vertex v and use it to star the hole whose boundary is described by the sequence of edges $[edge_begin, edge_end]$. Returns a pointer to the vertex.

```
template< class EdgeIt, class FaceIt>
Vertex_handle tds.star_hole( EdgeIt edge_begin, EdgeIt edge_end, FaceIt face_begin, FaceIt face_end)
```

same as above, except that, to build the new faces, the algorithm first recycles faces in the sequence $[face_begin, face_end]$ and create new ones when the sequence is exhausted.

```
template< class EdgeIt>
void tds.star_hole( Vertex_handle v, EdgeIt edge_begin, EdgeIt edge_end)
```

uses vertex v to star the hole whose boundary is described by the sequence of edges $[edge_begin, edge_end]$.

```
template< class EdgeIt, class FaceIt>
```

<i>void</i>	<i>tds.star_hole(Vertex_handle v, EdgeIt edge_begin, EdgeIt edge_end, FaceIt face_begin, FaceIt face_end)</i>	same as above, recycling faces in the sequence <i>[face_begin, face_end[</i> .
<i>void</i>	<i>tds.make_hole(Vertex_handle v, List_edges& hole)</i>	removes the vertex <i>v</i> , and store in <i>hole</i> the list of edges on the boundary of the hole.
<i>Vertex_handle</i>	<i>tds.create_vertex()</i>	adds a new vertex.
<i>Face_handle</i>	<i>tds.create_face(Face_handle f1, int i1, Face_handle f2, int i2, Face_handle f3, int i3)</i>	adds a face which is the neighbor <i>i1</i> of <i>f1</i> , <i>i2</i> of <i>f2</i> and <i>i3</i> of <i>f3</i> .
<i>Face_handle</i>	<i>tds.create_face(Face_handle f1, int i1, Face_handle f2, int i2)</i>	adds a face which is the neighbor <i>i1</i> of <i>f1</i> , and the neighbor <i>i2</i> of <i>f2</i> .
<i>Face_handle</i>	<i>tds.create_face(Face_handle f1, int i1, Vertex_handle v)</i>	adds a face which is the neighbor <i>i1</i> of <i>f1</i> , and has <i>v</i> as vertex.
<i>Face_handle</i>	<i>tds.create_face(Vertex_handle v1, Vertex_handle v2, Vertex_handle v3)</i>	adds a face with vertices <i>v1</i> , <i>v2</i> and <i>v3</i> .
<i>Face_handle</i>	<i>tds.create_face(Vertex_handle v1, Vertex_handle v2, Vertex_handle v3, Face_handle f1, Face_handle f2, Face_handle f3)</i>	adds a face with vertices <i>v1</i> , <i>v2</i> and <i>v3</i> , and neighbors <i>f1</i> , <i>f2</i> , <i>f3</i> .
<i>Face_handle</i>	<i>tds.create_face()</i>	adds a face whose vertices and neighbors are set to NULL.
<i>void</i>	<i>tds.delete_face(Face_handle)</i>	deletes a face.
<i>void</i>	<i>tds.delete_vertex(Vertex_handle)</i>	deletes a vertex.

_____ *advanced* _____

Miscellaneous

<i>int</i>	<i>tds.ccw(int i)</i>	returns $i + 1$ modulo 3. <i>Precondition:</i> $0 \leq i \leq 2$.
------------	------------------------	---

<i>int</i>	<i>tds.cw(int i)</i>	returns $i + 2$ modulo 3. <i>Precondition:</i> $0 \leq i \leq 2$.
<i>bool</i>	<i>tds.is_valid()</i>	checks the combinatorial validity of the triangulation: call the <i>is_valid()</i> member function for each vertex and each face, checks the number of vertices and the Euler relation between numbers of vertices, faces and edges.
<i>size_type</i>	<i>tds.degree(Vertex_handle v)</i>	Returns the degree of v in the triangulation.

I/O

The information output in the *iostream* is: the dimension, the number of (finite) vertices, the number of (finite) faces. Then comes for each vertex, the non combinatorial information stored in that vertex if any. Then comes for each faces, the indices of its vertices and the non combinatorial information (if any) stored in this face. Then comes for each face again the indices of the neighboring faces. The index of an item (vertex of face) the rank of this item in the output order. When dimension < 2 , the same information is output for faces of maximal dimension instead of faces.

void *tds.file_output(ostream& os, Vertex_handle v = Vertex_handle(), bool skip_first=false)*

writes *tds* into the stream *os*. If v is not a null handle, vertex v is output first or skipped if *skip_first* is true.

Vertex_handle *tds.file_input(istream& is, bool skip_first=false)*

inputs *tds* from file and returns a pointer to the first input vertex. If *skip_first* is true, it is assumed that the first vertex has been omitted when output.

istream& *istream& is >> TriangulationDataStructure_3 & tds*

reads a combinatorial triangulation from *is* and assigns it to *tds*

ostream& *ostream& os << TriangulationDataStructure_3 tds*

writes *tds* into the stream *os*

TriangulationDSFaceBase_2

Definition

The concept `TriangulationDSFaceBase_2` describes the requirements for the base face of a *Triangulation_data_structure_2* <*Vb.Fb*>.

Note that if the *Triangulation_data_structure_2* is plugged into a triangulation class, the face base class may have additional geometric requirements depending on the triangulation class.

At the base level, (see Sections 35.3 and 36.3), a face stores handles on its three vertices and on the three neighboring faces. The vertices and neighbors are indexed 0, 1 and 2. Neighbor i lies opposite to vertex i .

Since the *Triangulation_data_structure_2* is the class which defines the handle types, the face base class has to be somehow parameterized by the triangulation data structure. But since the *Triangulation_data_structure_2* itself is parameterized by the face and vertex base classes, there is a cycle in the definition of these classes. In order to break the cycle, the base classes for faces and vertices which are plugged in to instantiate a *Triangulation_data_structure_2* use a *void* as triangulation data structure parameter. Then, the *Triangulation_data_structure_2* uses a *rebind* mechanism (similar to the one specified in *std::allocator*) in order to plug itself as parameter in the face and vertex base classes. This mechanism requires that the base class provides a templated nested class *Rebind_TDS* that itself provides the subtype *Rebind_TDS<TDS>::Other* which is the *rebound* version of the base class. This *rebound* base class is the class that the *Triangulation_data_structure_2* actually uses as a base class for the class *Triangulation_data_structure_2::Face*.

Types

The concept `TriangulationDSFaceBase_2` has to provide the following types.

```
TriangulationDSFaceBase_2::template <typename TDS2> struct Rebind_TDS
```

This nested template class has to define a type *Other* which is the *rebound* face base, where the *Triangulation_data_structure_2* is actually plugged in. This type *Other* will be the actual base of the class *Triangulation_data_structure_2::Face*.

```
typedef TriangulationDataStructure_2 Triangulation_data_structure;
typedef TriangulationDataStructure_2::Vertex_handle Vertex_handle;
typedef TriangulationDataStructure_2::Face_handle Face_handle;
```

Creation

TriangulationDSFaceBase_2 f; default constructor.
TriangulationDSFaceBase_2 f(*Vertex_handle* v0, *Vertex_handle* v1, *Vertex_handle* v2);

Initializes the vertices with v_0 , v_1 , v_2 and the neighbors with *Face_handle()*.

TriangulationDSFaceBase_2 *f*(*Vertex_handle* *v0*,
 Vertex_handle *v1*,
 Vertex_handle *v2*,
 Face_handle *n0*,
 Face_handle *n1*,
 Face_handle *n2*)

initializes the vertices with *v0*, *v1*, *v2* and the neighbors with
n0, *n1*, *n2*.

Access Functions

<i>int</i>	<i>f.dimension()</i>	returns the dimension.
<i>Vertex_handle</i>	<i>f.vertex(int i)</i>	returns the vertex <i>i</i> of <i>f</i> . <i>Precondition:</i> $0 \leq i \leq 2$.
<i>bool</i>	<i>f.has_vertex(Vertex_handle v)</i>	returns true if <i>v</i> is a vertex of <i>f</i> .
<i>bool</i>	<i>f.has_vertex(Vertex_handle v, int& i)</i>	as above, and sets <i>i</i> to the index of <i>v</i> in <i>f</i> .
<i>int</i>	<i>f.index(Vertex_handle v)</i>	returns the index of <i>v</i> in <i>f</i> .
<i>Face_handle</i>	<i>f.neighbor(int i)</i>	returns the neighbor <i>i</i> of <i>f</i> . <i>Precondition:</i> $0 \leq i \leq 2$.
<i>bool</i>	<i>f.has_neighbor(Face_handle n)</i>	returns true if <i>n</i> is a neighbor of <i>f</i> .
<i>bool</i>	<i>f.has_neighbor(Face_handle n, int& i)</i>	as above, and sets <i>i</i> to the index of <i>n</i> in <i>f</i> .
<i>int</i>	<i>f.index(const Face_handle n)</i>	returns the index of neighbor <i>n</i> in <i>f</i> .

Setting

<i>void</i>	<i>f.set_vertex(int i, Vertex_handle v)</i>	sets vertex <i>i</i> to <i>v</i> . <i>Precondition:</i> $0 \leq i \leq 2$.
<i>void</i>	<i>f.set_vertices()</i>	sets the vertices to <i>Vertex_handle()</i> .
<i>void</i>	<i>f.set_vertices(Vertex_handle v0, Vertex_handle v1, Vertex_handle v2)</i>	sets the vertices.
<i>void</i>	<i>f.set_neighbor(int i, Face_handle n)</i>	sets neighbors <i>i</i> to <i>n</i> . <i>Precondition:</i> $0 \leq i \leq 2$.
<i>void</i>	<i>f.set_neighbors()</i>	sets the neighbors to <i>Face_handle()</i> .
<i>void</i>	<i>f.set_neighbors(Face_handle n0, Face_handle n1, Face_handle n2)</i>	sets the neighbors.

Orientation

<i>void</i>	<i>f.reorient()</i>	Changes the orientation of <i>f</i> by exchanging <i>vertex(0)</i> with <i>vertex(1)</i> and <i>neighbor(0)</i> with <i>neighbor(1)</i> .
<i>void</i>	<i>f.ccw_permute()</i>	performs a counterclockwise permutation of the vertices and neighbors of <i>f</i> .
<i>void</i>	<i>f.cw_permute()</i>	performs a clockwise permutation of the ver- tices and neighbors of <i>f</i> .

Checking

bool *f.is_valid(bool verbose = false)*

performs any required test on a face.
If *verbose* is set to *true*, messages are printed to give a precise indication of the kind of invalidity encountered.

Various

*void** *f.for_compact_container()*
void&* *f.for_compact_container()*

These member functions are required by *Triangulation_data_structure_2* because it uses *Compact_container* to store its faces. See the documentation of *Compact_container* for the exact requirements.

TriangulationDataStructure_2::Face

Definition

The concept `TriangulationDataStructure_2::Face` describes the types used to store the faces face class of a *TriangulationDataStructure_2*, see page [2419](#). A `TriangulationDataStructure_2::Face` stores three pointers to its three vertices and three pointers to its three neighbors. The vertices are indexed 0,1, and 2 in counterclockwise order. The neighbor indexed i lies opposite to vertex i .

In degenerate cases, when the triangulation data structure stores a simplicial complex of dimension 0 and 1, the type `TriangulationDataStructure_2::Face` is used to store the faces of maximal dimension of the complex : i.e. a vertex in dimension 0, an edge in dimension 1. Only vertices and neighbors with index 0 are set in the first case, only vertices and neighbors with index 0 or 1 are set in the second case.

Types

The class `TriangulationDataStructure_2::Face` defines the same types as the triangulation data structure except the iterators and the circulators.

Creation

The methods *create_face* and *delete_face()* have to be used to define new faces and to delete non longer used faces.

Vertex Access Functions

<i>Vertex_handle</i>	<i>f.vertex(int i)</i>	returns the vertex i of f . <i>Precondition:</i> $0 \leq i \leq 2$.
<i>int</i>	<i>f.index(Vertex_handle v)</i>	returns the index of vertex v in f . <i>Precondition:</i> v is a vertex of f
<i>bool</i>	<i>f.has_vertex(Vertex_handle v)</i>	returns <i>true</i> if v is a vertex of f .
<i>bool</i>	<i>f.has_vertex(Vertex_handle v, int& i)</i>	returns <i>true</i> if v is a vertex of f , and computes the index i of v in f .

Neighbor Access Functions

The neighbor with index i is the neighbor which is opposite to the vertex with index i .

<i>Face_handle</i>	<i>f.neighbor(int i)</i>	returns the neighbor i of f . <i>Precondition:</i> $0 \leq i \leq 2$.
<i>int</i>	<i>f.index(Face_handle n)</i>	returns the index of face n . <i>Precondition:</i> n is a neighbor of f .
<i>bool</i>	<i>f.has_neighbor(Face_handle n)</i>	returns <i>true</i> if n is a neighbor of f .
<i>bool</i>	<i>f.has_neighbor(Face_handle n, int& i)</i>	returns <i>true</i> if n is a neighbor of f , and compute the index i of n .

Setting

<i>void</i>	<i>f.set_vertex(int i, Vertex_handle v)</i>	sets vertex <i>i</i> to be <i>v</i> . <i>Precondition:</i> $0 \leq i \leq 2$.
<i>void</i>	<i>f.set_neighbor(int i, Face_handle n)</i>	sets neighbor <i>i</i> to be <i>n</i> . <i>Precondition:</i> $0 \leq i \leq 2$.
<i>void</i>	<i>f.set_vertices()</i>	sets the vertices pointers to <i>NULL</i> .
<i>void</i>	<i>f.set_vertices(Vertex_handle v0, Vertex_handle v1, Vertex_handle v2)</i>	sets the vertices pointers.
<i>void</i>	<i>f.set_neighbors()</i>	sets the neighbors pointers to <i>NULL</i> .
<i>void</i>	<i>f.set_neighbors(Face_handle n0, Face_handle n1, Face_handle n2)</i>	sets the neighbors pointers.

Checking

<i>bool</i>	<i>f.is_valid()</i>	returns <i>true</i> if the function <i>is_valid()</i> of the base class returns <i>true</i> and if, for each index <i>i</i> , $0 \leq i < 3$, face <i>f</i> is a neighbor of its neighboring face <i>neighbor(i)</i> and shares with this neighbor the vertices <i>cw(i)</i> and <i>ccw(i)</i> in correct reverse order.
-------------	---------------------	---

Miscellaneous

<i>int</i>	<i>f.ccw(int i)</i>	Returns $i + 1$ modulo 3. <i>Precondition:</i> $0 \leq i \leq 2$.
<i>int</i>	<i>f.cw(int i)</i>	Returns $i + 2$ modulo 3. <i>Precondition:</i> $0 \leq i \leq 2$.

I/O

<i>istream&</i>	<i>istream& is >> &f</i>	Inputs any non combinatorial information possibly stored in the face.
<i>ostream&</i>	<i>ostream& os << f</i>	Outputs any non combinatorial information possibly stored in the face.

TriangulationDSVertexBase_2

Definition

The concept `TriangulationDSVertexBase_2` describes the requirements for the vertex base class of a `Triangulation_data_structure_2<Vb,Fb>`.

Note that if the `Triangulation_data_structure_2` is plugged into a triangulation class, the vertex base class has additional geometric requirements depending on the triangulation class.

At the base level, provides access to one of its incident face through a *Face_handle*.

Since the `Triangulation_data_structure_2` is the class which defines the handle types, the vertex base class has to be somehow parameterized by the triangulation data structure. But since the `Triangulation_data_structure_2` itself is parameterized by the face and vertex base classes, there is a cycle in the definition of these classes. In order to break the cycle, the base classes for faces and vertices which are plugged in to instantiate a `Triangulation_data_structure_2` use a *void* as triangulation data structure parameter. Then, the `Triangulation_data_structure_2` uses a *rebind* mechanism (similar to the one specified in `std::allocator`) in order to plug itself as parameter in the face and vertex base classes. This mechanism requires that the base class provides a templated nested class *Rebind_TDS* that itself provides the subtype *Rebind_TDS<TDS2>::Other* which is the *rebound* version of the base class. This *rebound* base class is the class that the `Triangulation_data_structure_2` actually uses as a base class for the class of `Triangulation_data_structure_2::Vertex`.

Refines

`TriangulationDataStructure_2::Vertex`

Types

The concept `TriangulationDSVertexBase_2` has to provide the following types.

`TriangulationDSVertexBase_2::template <typename TDS2> struct Rebind_TDS`

This nested template class has to define a type *Other* which is the *rebound* vertex base , where the actual `Triangulation_data_structure_2` is plugged in. This type *Other* will be the actual base of the class `Triangulation_data_structure_2::Vertex`.

<code>typedef TriangulationDataStructure_2</code>	<code>Triangulation_data_structure;</code>
<code>typedef TriangulationDataStructure_2::Vertex_handle</code>	<code>Vertex_handle;</code>
<code>typedef TriangulationDataStructure_2::Face_handle</code>	<code>Face_handle;</code>

Creation

<code>TriangulationDSVertexBase_2 v;</code>	default constructor.
<code>TriangulationDSVertexBase_2 v(Face_handle f);</code>	Constructs a vertex pointing to face <i>f</i> .

Various

```
void*          v.for_compact_container()
void*&          v.for_compact_container()
```

These member functions are required by *Triangulation_data_structure_2* because it uses *Compact_container* to store its faces. See the documentation of *Compact_container* for the exact requirements.

TriangulationDataStructure_2::Vertex

Definition

The concept `TriangulationDataStructure_2::Vertex` describes the type used by a *TriangulationDataStructure_2* to store the vertices, see page [2419](#).

Some of the requirements listed below are of geometric nature and are *optional* when using the triangulation data structure class alone. They became required when the triangulation data structure is plugged into a triangulation.

Types

The class `TriangulationDataStructure_2::Vertex` defines the same types as the triangulation data structure except the iterators.

TriangulationDataStructure_2::Vertex::Point *Optional for the triangulation data structure used alone.*

Creation

In order to obtain new vertices or destruct unused vertices, the user must call the *create_vertex()* and *delete_vertex()* methods of the triangulation data structure.

Access Functions

<i>Point</i>	<i>v.point()</i>	returns the geometric information of <i>v</i> .
<i>Face_handle</i>	<i>v.face()</i>	returns a face of the triangulation having <i>v</i> as vertex.

————— *advanced* —————

Setting

<i>void</i>	<i>v.set_point(Point p)</i>	sets the geometric information to <i>p</i> .
<i>void</i>	<i>v.set_face(Face_handle f)</i>	sets the incident face to <i>f</i> .

————— *advanced* —————

Checking

<i>bool</i>	<i>v.is_valid(bool verbose = false)</i>
-------------	--

Checks the validity of the vertex. Must check that its incident face has this vertex. The validity of the base vertex is also checked. When *verbose* is set to *true*, messages are printed to give a precise indication on the kind of invalidity encountered.

I/O

istream& *istream*& *is* >> & *v* Inputs the non-combinatorial information possibly stored in the vertex.

ostream& *ostream*& *os* << *v* Outputs the non combinatorial operation possibly stored in the vertex.

CGAL::Triangulation_data_structure_2<Vb,Fb>

Definition

The class *Triangulation_data_structure_2<Vb,Fb>* is a model for the *TriangulationDataStructure_2* concept. It can be used to represent an orientable 2D triangulation embedded in a space of any dimension.

The vertices and faces are stored in two nested containers, which are implemented using *CGAL::Compact_container*. The class may offer some flexibility for the choice of container in the future, in the form of additional template parameters.

```
#include <CGAL/Triangulation_data_structure_2.h>
```

Is Model for the Concepts

TriangulationDataStructure_2

— advanced —

In addition to the interface documented in the concept, the class offers the following types and functions.

Types

```
typedef CGAL::Compact_container<Vertex>
```

```

                                Vertex_range;      Vertex container type.
typedef CGAL::Compact_container<Face>
```

```
                                Face_range;        Face container type.
```

Operations

<i>Face_range&</i>	<i>tds.faces()</i>	Returns a reference to the container of faces.
<i>Face_range&</i>	<i>tds.faces()</i>	Returns a reference to the container of faces.
<i>Vertex_range&</i>	<i>tds.vertices()</i>	Returns a reference to the container of vertices.
<i>Vertex_range&</i>	<i>tds.vertices()</i>	Returns a reference to the container of vertices.

— advanced —

Modifiers

In addition to the modifiers required by the *TriangulationDataStructure_2* concept, the *Triangulation_data_structure_2<Vb,Fb>* class supports also the modifiers below. Note also that the modifiers below guarantee the combinatorial validity of the resulting data structure.

<i>Vertex_handle</i>	<i>tds.join_vertices(Face_handle f, int i)</i>	Joins the vertices that are endpoints of the edge (<i>f</i> , <i>i</i>). It returns a vertex handle to common vertex (see Fig. 36.7). <i>Precondition:</i> <i>f</i> must be different from <i>Face_handle()</i> and <i>i</i> must be 0, 1 or 2.
----------------------	--	--

<i>Vertex_handle</i>	<code>tds.join_vertices(Edge <i>e</i>)</code>	Joins the vertices that are endpoints of the edge <i>e</i> . It returns a vertex handle to common vertex.
<i>Vertex_handle</i>	<code>tds.join_vertices(Edge_iterator <i>eit</i>)</code>	Joins the vertices that are endpoints of the edge * <i>eit</i> . It returns a vertex handle to common vertex.
<i>Vertex_handle</i>	<code>tds.join_vertices(Edges_circulator <i>ec</i>)</code>	Joins the vertices that are endpoints of the edge * <i>ec</i> . It returns a vertex handle to common vertex.

`boost::tuples::tuple<Vertex_handle, Vertex_handle, Face_handle, Face_handle>`

`tds.split_vertex(Vertex_handle v, Face_handle f1, Face_handle f2)`

Splits the vertex *v* into two vertices *v1* and *v2*. The common faces *f* and *g* of *v1* and *v2* are created after (in the counter-clockwise sense) the faces *f1* and *f2*. The 4-tuple (*v1*, *v2*, *f*, *g*) is returned (see Fig. 36.7).
Precondition: `dimension()` must be equal to 2, *f1* and *f2* must be different from `Face_handle()` and *v* must be a vertex of both *f1* and *f2*.

<i>Vertex_handle</i>	<code>tds.insert_degree_2(Face_handle <i>f</i>, int <i>i</i>)</code>	Inserts a degree two vertex and two faces adjacent to it that have two common edges. The edge defined by the face handle <i>f</i> and the integer <i>i</i> is duplicated. It returns a handle to the vertex created (see Fig. 36.8).
----------------------	--	--

<code>void</code>	<code>tds.remove_degree_2(Vertex_handle <i>v</i>)</code>	Removes a degree 2 vertex and the two faces adjacent to it. The two edges of the star of <i>v</i> that are not incident to it are collapsed (see Fig. 36.8). <i>Precondition:</i> The degree of <i>v</i> must be equal to 2.
-------------------	--	---

The basic 3D-triangulation class of CGAL is primarily designed to represent the triangulations of a set of points A in \mathbb{R}^3 . It is a partition of the convex hull of A into tetrahedra whose vertices are the points of A . Together with the unbounded cell having the convex hull boundary as its frontier, the triangulation forms a partition of \mathbb{R}^3 . Its cells (3-faces) are such that two cells either do not intersect or share a common facet (2-face), edge (1-face) or vertex (0-face).

37.1 Representation

In order to deal only with tetrahedra, which is convenient for many applications, the unbounded cell can be subdivided into tetrahedra by considering that each convex hull facet is incident to an *infinite cell* having as fourth vertex an auxiliary vertex called the *infinite vertex*. In that way, each facet is incident to exactly two cells and special cases at the boundary of the convex hull are simple to deal with.

The class `Triangulation_3<TriangulationTraits_3, TriangulationDataStructure_3>` of CGAL implements this point of view and therefore considers the triangulation of the set of points as a set of finite and infinite tetrahedra. Notice that the infinite vertex has no significant coordinates and that no geometric predicate can be applied on it.

A triangulation is a collection of vertices and cells that are linked together through incidence and adjacency relations. Each cell gives access to its four incident vertices and to its four adjacent cells. Each vertex gives access to one of its incident cells.

The four vertices of a cell are indexed with 0, 1, 2 and 3 in positive orientation, the positive orientation being defined by the orientation of the underlying Euclidean space \mathbb{R}^3 (see Figure 37.1). The neighbors of a cell are also indexed with 0, 1, 2, 3 in such a way that the neighbor indexed by i is opposite to the vertex with the same index.

As in the underlying combinatorial triangulation (see Chapter 38), edges (1-faces) and facets (2-faces) are not explicitly represented: a facet is given by a cell and an index (the facet i of a cell c is the facet of c that is opposite to the vertex with index i) and an edge is given by a cell and two indices (the edge (i, j) of a cell c is the edge whose endpoints are the vertices of c with indices i and j). See Figure 38.1.

Degenerate Dimensions The class `Triangulation_3` can also deal with triangulations whose dimension d is less than 3. A triangulation of a set of points in \mathbb{R}^d covers the whole space \mathbb{R}^d and consists of cells having $d + 1$ vertices: some of them are infinite, they are obtained by linking the additional infinite vertex to each facet of the convex hull of the points.

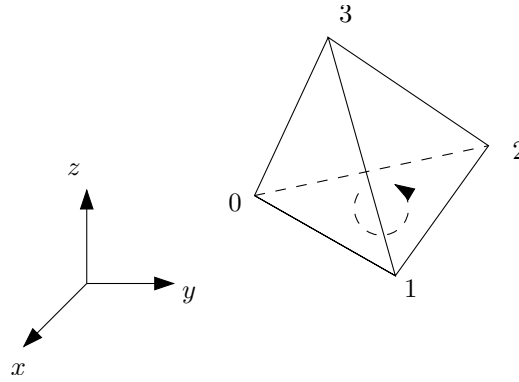

Figure 37.1: Orientation of a cell (3-dimensional case).

- *dimension 2*: when a triangulation only contains coplanar points (which is the case when there are only three points), it consists of triangular faces.
- *dimension 1*: the triangulation contains only collinear points (which is the case when there are only two points), it consists of edges.
- *dimension 0*: the triangulation contains only one finite point.
- *dimension -1*: this is a convention to handle the case when the only vertex of the triangulation is the infinite one.

The same cell class is used in all cases: triangular faces in 2D can be considered as degenerate cells, having only three vertices (resp. neighbors) numbered (0, 1, 2); edges in 1D have only two vertices (resp. neighbors) numbered 0 and 1.

The implicit representation of facets (resp. edges) still holds for degenerate dimensions (*i.e.* dimensions < 3): in dimension 2, each cell has only one facet of index 3, and 3 edges (0, 1), (1, 2) and (2, 0); in dimension 1, each cell has one edge (0, 1).

Validity A triangulation of \mathbb{R}^3 is said to be *locally valid* iff

- (a)-(b) Its underlying combinatorial graph, the triangulation data structure, is *locally valid* (see Section 38.1 of Chapter 38)
- (c) Any cell has its vertices ordered according to positive orientation. See Figure 37.1.

When the triangulation is degenerated into a triangulation of dimension 2, the geometric validity reduces to:

(c-2D) For any two adjacent triangles (u, v, w_1) and (u, v, w_2) with common edge (u, v) , w_1 and w_2 lie on opposite sides of (u, v) in the plane.

When all the points are collinear, this condition becomes:

(c-1D) For any two adjacent edges (u, v) and (v, w) , u and w lie on opposite sides of the common vertex v on the line.

The *is_valid()* method provided in *Triangulation_3* checks the local validity of a given triangulation. This does not always ensure global validity [MNS⁺96, DLPT98] but it is sufficient for practical cases.

37.2 Delaunay Triangulation

The class *Delaunay_triangulation_3* represents a three-dimensional Delaunay triangulation.

Delaunay triangulations have the specific *empty sphere property*, that is, the circumscribing sphere of each cell of such a triangulation does not contain any other vertex of the triangulation in its interior. These triangulations are uniquely defined except in degenerate cases where five points are co-spherical. Note however that the CGAL implementation computes a unique triangulation even in these cases.

This implementation is fully dynamic: it supports insertions of points, vertex removals and displacements of points.

37.3 Regular Triangulation

The class *Regular_triangulation_3* implements incremental regular triangulations, also known as weighted Delaunay triangulations.

Let $S^{(w)}$ be a set of weighted points in \mathbb{R}^3 . Let $p^{(w)} = (p, w_p)$, $p \in \mathbb{R}^3$, $w_p \in \mathbb{R}$ and $z^{(w)} = (z, w_z)$, $z \in \mathbb{R}^3$, $w_z \in \mathbb{R}$ be two weighted points. A weighted point $p^{(w)} = (p, w_p)$ can also be seen as a sphere of center p and radius $\sqrt{w_p}$. The *power product* between $p^{(w)}$ and $z^{(w)}$ is defined as

$$\Pi(p^{(w)}, z^{(w)}) = \|p - z\|^2 - w_p - w_z$$

where $\|p - z\|$ is the Euclidean distance between p and z . $p^{(w)}$ and $z^{(w)}$ are said to be *orthogonal* iff $\Pi(p^{(w)}, z^{(w)}) = 0$ (see Figure 37.2).

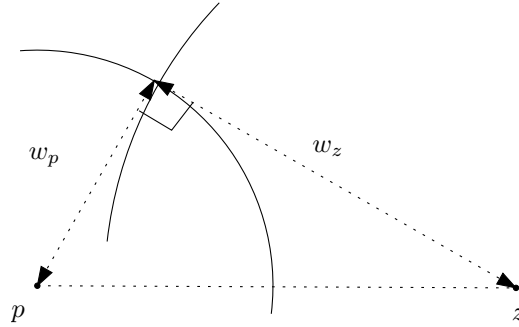

Figure 37.2: Orthogonal weighted points (picture in 2D).

Four weighted points have a unique common orthogonal weighted point called the *power sphere*. The weighted point orthogonal to three weighted points in the plane defined by these three points is called the *power circle*. The *power segment* will denote the weighted point orthogonal to two weighted points on the line defined by these two points.

A sphere $z^{(w)}$ is said to be *regular* if $\forall p^{(w)} \in S^{(w)}, \Pi(p^{(w)}, z^{(w)}) \geq 0$.

A triangulation of $S^{(w)}$ is *regular* if the power spheres of all simplices are regular.

The regular triangulation of $S^{(w)}$ is in fact the projection onto \mathbb{R}^3 of the convex hull of the four-dimensional points $(p, \|p - O\|^2 - w_p)$, for $p^{(w)} = (p, w_p) \in S^{(w)}$. Note that all points of $S^{(w)}$ do not necessarily appear as vertices of the regular triangulation. To know more about regular triangulations, see for example [ES96].

When all weights are 0, power spheres are nothing more than circumscribing spheres, and the regular triangulation is exactly the Delaunay triangulation.

The implementation of 3D regular triangulation supports insertions of weighted points, and vertex removals. Displacements are not supported in the current implementation.

37.4 Software Design

The main classes *Triangulation_3*, *Delaunay_triangulation_3* and *Regular_triangulation_3* are connected to each other by the derivation diagram shown in Figure 37.3. This diagram also shows another class: *Triangulation_utils_3* (page 2570), which provides a set of tools operating on the indices of vertices in cells.

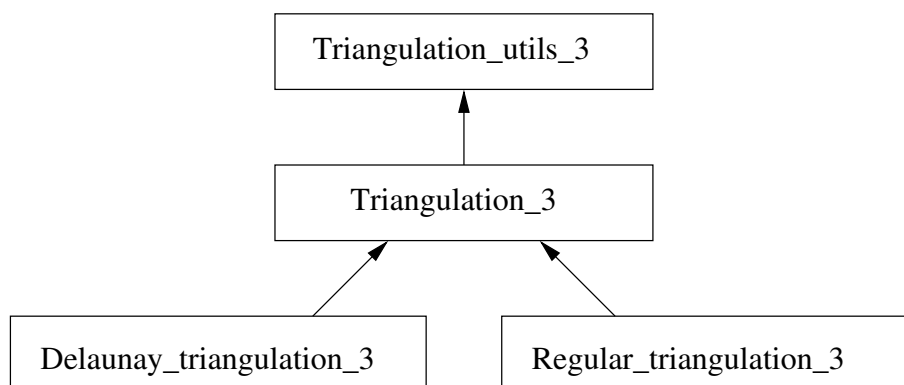

Figure 37.3: Derivation diagram of the 3D triangulation classes.

The three main classes (*Triangulation_3*, *Delaunay_triangulation_3* and *Regular_triangulation_3*) provide high-level geometric functionality such as location of a point in the triangulation [DPT02], insertion and possibly removal of a point [DT03], and are responsible for the geometric validity. They are built as layers on top of a triangulation data structure, which stores their combinatorial structure. This separation between the geometry and the combinatorics is reflected in the software design by the fact that these three triangulation classes take the following template parameters :

- the **geometric traits** class, which provides the type of points to use as well as the elementary operations on them (predicates and constructions). The concepts for these parameters are described in more details in Section 37.4.1 and in page 2500.
- the **triangulation data structure** class, which stores their combinatorial structure, described in Section 38.2 of Chapter 38.
- the **location policy** tag, which is supported only by the Delaunay triangulation class, described in Section 37.4.3.

37.4.1 The Geometric Traits Parameter

The first template parameter of the triangulation class *Triangulation_3*<*TriangulationTraits_3*, *TriangulationDataStructure_3*> is the geometric traits class, described by the concept *TriangulationTraits_3*. It must define the types of the geometric objects (points, segments, triangles and tetrahedra) forming the

triangulation together with a few geometric predicates on these objects: orientation in space, orientation in case of coplanar points, order of collinear points.

In addition to the requirements described before, the geometric traits class of *Delaunay_triangulation_3* must define predicates to test for the *empty sphere property*. It is described by the concept *DelaunayTriangulationTraits_3*, which refines *TriangulationTraits_3*.

The kernels provided by CGAL: *Cartesian*, *Homogeneous*, *Simple_cartesian*, *Simple_homogeneous* and *Filtered_kernel* can all be used as models for the geometric traits parameter. They supply the user with all the functionalities described for the concepts *TriangulationTraits_3* (page 2500) and *DelaunayTriangulationTraits_3* (page 2502). In addition, the predefined kernels *Exact_predicates_inexact_constructions_kernel* (page ??) and *Exact_predicates_exact_constructions_kernel* (page ??) can also be used, the latter being recommended when the dual construction is used.

In order to be used as the traits class for *Regular_triangulation_3*, a class must provide functions to compute the *power tests* (see Section 37.3). *Regular_triangulation_euclidean_traits_3<K,Weight>* is a traits class designed to be used by the class *Regular_triangulation_3<RegularTriangulationTraits_3, TriangulationDataStructure_3>*. It provides *Weighted_point*, a class for weighted points needed by the regular triangulation, which derives from the three dimensional point class *K::Point_3*. It supplies the user with all the functionalities described for the concept *RegularTriangulationTraits_3* (page 2505). It can be used as a traits class for *Regular_triangulation_3<RegularTriangulationTraits_3, TriangulationDataStructure_3>*.

Note that for regular triangulations, plugging a filtered kernel such as *Exact_predicates_inexact_constructions_kernel* or *Exact_predicates_exact_constructions_kernel* in *Regular_triangulation_euclidean_traits_3<K,Weight>* will provide exact and efficient filtered predicates.

37.4.2 The Triangulation Data Structure Parameter

The second template parameter of the main classes (*Triangulation_3*, *Delaunay_triangulation_3* and *Regular_triangulation_3*) is a triangulation data structure class. This class can be seen as a container for the cells and vertices maintaining incidence and adjacency relations (see Chapter 38). A model of this triangulation data structure is *Triangulation_data_structure_3* (page 2566), and it is described by the *TriangulationDataStructure_3* concept (page 2543). This model is itself parameterized by a vertex base and a cell base classes, which gives the possibility to customize the vertices and cells used by the triangulation data structure, and hence by the geometric triangulation using it. Depending on the kind of triangulation used, the requirements on the vertex and cell base classes vary, and are expressed by various concepts, following the refinement diagram shown in Figure 37.4.

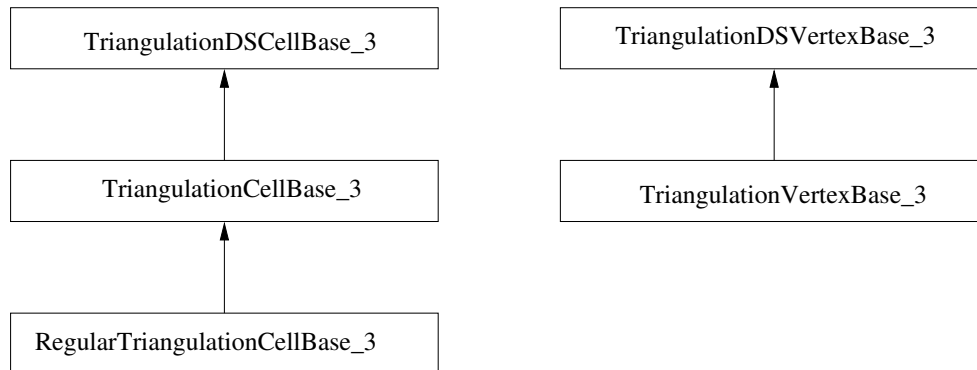

Figure 37.4: Concepts refinement hierarchy for the vertex and cell base classes parameters.

A default value for the triangulation data structure parameter is provided in all the triangulation classes, so it need not be specified by the user unless he wants to use a different triangulation data structure or a different vertex or cell base class.

37.4.3 The Location Policy Parameter

The Delaunay triangulation class supports an optional feature which maintains an additional data structure for fast point location queries. The fast location policy should be used when the user inserts points in a random order or needs to do many unrelated queries. If the user is able to give a good hint to help the point location of its queries (and its newly inserted points), then it should prefer the default policy. In such a case where good hints are provided, the default policy save some memory (few percents), and is faster. Notice that if points are not inserted one by one, but as a range, then a good hint is automatically computed using spatial sort.

Reading Section 37.6 on complexity and performance can help making an informed choice for this parameter.

The point location strategy can be selected with the third template argument of *Delaunay_triangulation_3*, *LocationPolicy*, which enables a fast point location data structure when set to *Fast_location*. By default, it uses *Compact_location*.

Note that you can specify the *LocationPolicy* parameter without specifying the triangulation data structure, in case you are fine with the default there. In this case, the *LocationPolicy* appears as a second parameter after the geometric traits.¹

The *Fast_location* policy is implemented using a hierarchy of triangulations; it changes the behavior of functions *locate*, *insert*, *move*, and *remove*. As proved in [Dev02], this structure has an optimal behavior when it is built for Delaunay triangulations.

In this setting, if you build a triangulation by iteratively inserting points, you should try to shuffle the points beforehand, as the time complexity is guaranteed only for a randomized order. For example, inserting points in lexicographic order is typically much slower. Note that this shuffling is performed internally by the constructor taking a range of points.

Prior to CGAL 3.6, this functionality was available through the *Triangulation_hierarchy_3* class, which is now deprecated.

37.4.4 Flexibility of the Design

In order to satisfy as many uses as possible, a design has been selected that allows to exchange different parts to meet the users' needs, while still re-using a maximum of the provided functionalities. We have already seen that the main triangulation classes are parameterized by a geometric traits class and a triangulation data structure (TDS), so that each of them can be interchanged with alternate implementations.

The most useful flexibility is the ability given to the user to add his own data in the vertices and cells by providing his own vertex and cell base classes to *Triangulation_data_structure_3*. The Figure 37.5 shows in more detail the flexibility that is provided, and the place where the user can insert his own vertex and/or cell base classes.

The design of the triangulation data structure gives the possibility to store any kind of data, including handles (an entity akin to pointers) directly in the vertex and cell base classes.

To do so, there are three possibilities. The simplest one is to use the class *Triangulation_vertex_base_with_info_3*, and this approach is illustrated in a following subsection 37.5.2. The most complicated one, and probably

¹The mechanism used behind the scenes to allow this syntactical convenience is called *deduced parameters*.

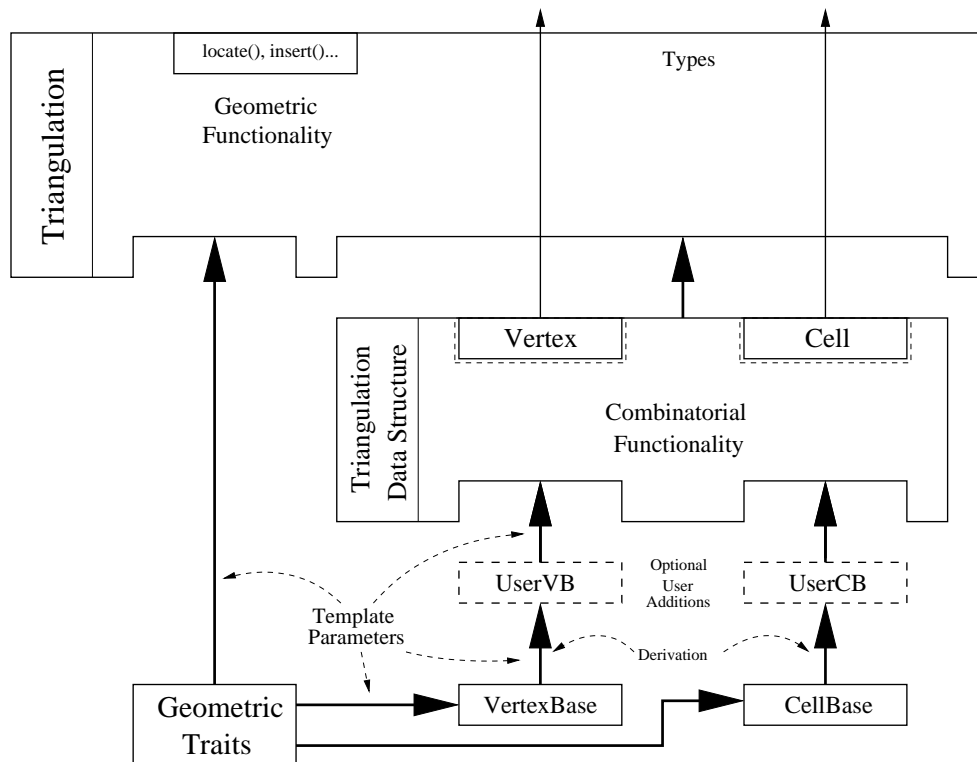

Figure 37.5: Triangulation software design.

useless for almost all cases, is to write a vertex base class from scratch, following the documented requirements. This is mostly useless because most of the time it is enough to derive from the models that CGAL provides, and add the desired features. In this case, when the user needs to access some type that depends on the triangulation data structure (typically handles), then he should write something like:

```
...
template < class GT, class Vb = Triangulation_vertex_base<GT> >
class My_vertex
: public Vb
{
public:
    typedef typename Vb::Point          Point;
    typedef typename Vb::Cell_handle    Cell_handle;

    template < class TDS2 >
    struct Rebind_TDS {
        typedef typename Vb::template Rebind_TDS<TDS2>::Other    Vb2;
        typedef My_vertex<GT, Vb2>                                Other;
    };

    My_vertex() {}
    My_vertex(const Point&p) : Vb(p) {}
    My_vertex(const Point&p, Cell_handle c) : Vb(p, c) {}
...
};
... // The rest has not changed
```

The situation is exactly similar for cell base classes. Section [38.2](#) provides more detailed information.

37.5 Examples

37.5.1 Basic Example

This example shows the incremental construction of a 3D triangulation, the location of a point and how to perform elementary operations on indices in a cell. It uses the default parameter of the *Triangulation_3* class.

```
#include <CGAL/Exact_predicates_inexact_constructions_kernel.h>
#include <CGAL/Triangulation_3.h>

#include <iostream>
#include <fstream>
#include <cassert>
#include <list>
#include <vector>

typedef CGAL::Exact_predicates_inexact_constructions_kernel K;

typedef CGAL::Triangulation_3<K>      Triangulation;

typedef Triangulation::Cell_handle    Cell_handle;
typedef Triangulation::Vertex_handle Vertex_handle;
typedef Triangulation::Locate_type    Locate_type;
typedef Triangulation::Point          Point;

int main()
{
    // construction from a list of points :
    std::list<Point> L;
    L.push_front(Point(0,0,0));
    L.push_front(Point(1,0,0));
    L.push_front(Point(0,1,0));

    Triangulation T(L.begin(), L.end());

    Triangulation::size_type n = T.number_of_vertices();

    // insertion from a vector :
    std::vector<Point> V(3);
    V[0] = Point(0,0,1);
    V[1] = Point(1,1,1);
    V[2] = Point(2,2,2);

    n = n + T.insert(V.begin(), V.end());

    assert( n == 6 );           // 6 points have been inserted
    assert( T.is_valid() );    // checking validity of T

    Locate_type lt;
    int li, lj;
```

```

Point p(0,0,0);
Cell_handle c = T.locate(p, lt, li, lj);
// p is the vertex of c of index li :
assert( lt == Triangulation::VERTEX );
assert( c->vertex(li)->point() == p );

Vertex_handle v = c->vertex( (li+1)&3 );
// v is another vertex of c
Cell_handle nc = c->neighbor(li);
// nc = neighbor of c opposite to the vertex associated with p
// nc must have vertex v :
int nli;
assert( nc->has_vertex( v, nli ) );
// nli is the index of v in nc

std::ofstream oFileT("output",std::ios::out);
// writing file output;
oFileT << T;

Triangulation T1;
std::ifstream iFileT("output",std::ios::in);
// reading file output;
iFileT >> T1;
assert( T1.is_valid() );
assert( T1.number_of_vertices() == T.number_of_vertices() );
assert( T1.number_of_cells() == T.number_of_cells() );

return 0;
}

```

37.5.2 Changing the Vertex Base

The following two examples show how the user can plug his own vertex base in a triangulation. Changing the cell base is similar.

Adding a Color

When the user doesn't need to add a type in a vertex which depends on the *TriangulationDataStructure_3* (e.g. a *Vertex_handle* or *Cell_handle*), then he can use the *Triangulation_vertex_base_with_info_3* class to add his own information easily in the vertices. The example below shows how to add a *CGAL::Color* this way.

```

#include <CGAL/Exact_predicates_inexact_constructions_kernel.h>
#include <CGAL/Delaunay_triangulation_3.h>
#include <CGAL/Triangulation_vertex_base_with_info_3.h>
#include <CGAL/IO/Color.h>

typedef CGAL::Exact_predicates_inexact_constructions_kernel K;

```

```

typedef CGAL::Triangulation_vertex_base_with_info_3<CGAL::Color, K> Vb;
typedef CGAL::Triangulation_data_structure_3<Vb> Tds;
typedef CGAL::Delaunay_triangulation_3<K, Tds>
    Delaunay;

typedef Delaunay::Point    Point;

int main()
{
    Delaunay T;

    T.insert(Point(0,0,0));
    T.insert(Point(1,0,0));
    T.insert(Point(0,1,0));
    T.insert(Point(0,0,1));
    T.insert(Point(2,2,2));
    T.insert(Point(-1,0,1));

    // Set the color of finite vertices of degree 6 to red.
    Delaunay::Finite_vertices_iterator vit;
    for (vit = T.finite_vertices_begin(); vit != T.finite_vertices_end();
        ++vit)
        if (T.degree(vit) == 6)
            vit->info() = CGAL::RED;

    return 0;
}

```

File: examples/Triangulation_3/color.cpp

Adding Handles

When the user needs to add a type in a vertex which depends on the *TriangulationDataStructure_3* (e.g. a *Vertex_handle* or *Cell_handle*), then he has to derive his own vertex base class, as the following example shows.

```

#include <CGAL/Exact_predicates_inexact_constructions_kernel.h>
#include <CGAL/Delaunay_triangulation_3.h>
#include <CGAL/Triangulation_vertex_base_3.h>

template < class GT, class Vb = CGAL::Triangulation_vertex_base_3<GT> >
class My_vertex_base
: public Vb
{
public:
    typedef typename Vb::Vertex_handle    Vertex_handle;
    typedef typename Vb::Cell_handle      Cell_handle;
    typedef typename Vb::Point            Point;

    template < class TDS2 >
    struct Rebind_TDS {
        typedef typename Vb::template Rebind_TDS<TDS2>::Other    Vb2;
        typedef My_vertex_base<GT, Vb2>                          Other;
    };
};

```

```

};

My_vertex_base() {}

My_vertex_base(const Point& p)
: Vb(p) {}

My_vertex_base(const Point& p, Cell_handle c)
: Vb(p, c) {}

Vertex_handle   vh;
Cell_handle     ch;
};

typedef CGAL::Exact_predicates_inexact_constructions_kernel K;

typedef CGAL::Triangulation_data_structure_3<My_vertex_base<K> >   Tds;
typedef CGAL::Delaunay_triangulation_3<K, Tds>
    Delaunay;

typedef Delaunay::Vertex_handle   Vertex_handle;
typedef Delaunay::Point           Point;

int main()
{
    Delaunay T;

    Vertex_handle v0 = T.insert(Point(0,0,0));
    Vertex_handle v1 = T.insert(Point(1,0,0));
    Vertex_handle v2 = T.insert(Point(0,1,0));
    Vertex_handle v3 = T.insert(Point(0,0,1));
    Vertex_handle v4 = T.insert(Point(2,2,2));
    Vertex_handle v5 = T.insert(Point(-1,0,1));

    // Now we can link the vertices as we like.
    v0->vh = v1;
    v1->vh = v2;
    v2->vh = v3;
    v3->vh = v4;
    v4->vh = v5;
    v5->vh = v0;

    return 0;
}

```

File: examples/Triangulation_3/adding_handles_3.cpp

37.5.3 The Simplex Class

The triangulation defines a *Simplex* class that represents a simplex (vertex, edge, facet or cell). This example demonstrates how simplices can be stored in a set.

```

#include <CGAL/Exact_predicates_inexact_constructions_kernel.h>
#include <CGAL/Triangulation_3.h>

#include <iostream>
#include <fstream>
#include <list>
#include <set>

typedef CGAL::Exact_predicates_inexact_constructions_kernel K;

typedef CGAL::Triangulation_3<K>      Triangulation;

typedef Triangulation::Finite_vertices_iterator Finite_vertices_iterator;
typedef Triangulation::Finite_edges_iterator Finite_edges_iterator;
typedef Triangulation::Finite_facets_iterator Finite_facets_iterator;
typedef Triangulation::Finite_cells_iterator Finite_cells_iterator;
typedef Triangulation::Simplex        Simplex;
typedef Triangulation::Locate_type     Locate_type;
typedef Triangulation::Point          Point;

int main()
{
    // construction from a list of points :
    std::list<Point> L;
    L.push_front(Point(0,0,0));
    L.push_front(Point(1,0,0));
    L.push_front(Point(0,1,0));
    L.push_front(Point(0,1,1));

    Triangulation T(L.begin(), L.end());

    std::set<Simplex> simplices;

    Finite_vertices_iterator vit = T.finite_vertices_begin();
    simplices.insert(Simplex(vit));

    Finite_cells_iterator cit = T.finite_cells_begin();
    simplices.insert(Simplex(cit));

    Finite_edges_iterator eit = T.finite_edges_begin();
    simplices.insert(Simplex(*eit));

    Finite_facets_iterator fit = T.finite_facets_begin();
    simplices.insert(Simplex(*fit));

    for (std::set<Simplex>::iterator it = simplices.begin();
         it != simplices.end(); it++) {
        std::cout << it->dimension() << std::endl;
    }

    return 0;
}

```

File: examples/Triangulation_3/simplex.cpp

37.5.4 Fast Point Location for Delaunay Triangulations

```
#include <CGAL/Exact_predicates_inexact_constructions_kernel.h>
#include <CGAL/Delaunay_triangulation_3.h>
#include <CGAL/Random.h>

#include <vector>
#include <cassert>

typedef CGAL::Exact_predicates_inexact_constructions_kernel K;
typedef CGAL::Delaunay_triangulation_3<K, CGAL::Fast_location> Delaunay;
typedef Delaunay::Point Point;

int main()
{
    // generating points on a grid.
    std::vector<Point> P;

    for (int z=0 ; z<20 ; z++)
        for (int y=0 ; y<20 ; y++)
            for (int x=0 ; x<20 ; x++)
                P.push_back(Point(x,y,z));

    // building their Delaunay triangulation.
    Delaunay T(P.begin(), P.end());

    assert( T.number_of_vertices() == 8000 );

    // performing nearest vertex queries to a series of random points,
    // which is a case where the Fast_location policy is beneficial.
    for (int i=0; i<10000; ++i)
        T.nearest_vertex(Point(CGAL::default_random.get_double(0, 20),
                               CGAL::default_random.get_double(0, 20),
                               CGAL::default_random.get_double(0, 20)));

    return 0;
}
```

File: examples/Triangulation_3/fast_location_3.cpp

37.5.5 Finding the Cells in Conflict with a Point in a Delaunay Triangulation

```
#include <CGAL/Exact_predicates_inexact_constructions_kernel.h>
#include <CGAL/Delaunay_triangulation_3.h>
#include <CGAL/point_generators_3.h>

#include <vector>
#include <cassert>
```

```

typedef CGAL::Exact_predicates_inexact_constructions_kernel K;

typedef CGAL::Delaunay_triangulation_3<K>           Delaunay;
typedef Delaunay::Point                             Point;
typedef Delaunay::Cell_handle                       Cell_handle;
typedef Delaunay::Facet                             Facet;

int main()
{
    Delaunay T;
    CGAL::Random_points_in_sphere_3<Point> rnd;

    // First, make sure the triangulation is 3D.
    T.insert(Point(0,0,0));
    T.insert(Point(1,0,0));
    T.insert(Point(0,1,0));
    T.insert(Point(0,0,1));

    assert(T.dimension() == 3);

    // Inserts 100 random points if and only if their insertion
    // in the Delaunay tetrahedralization conflicts with
    // an even number of cells.
    for (int i = 0; i != 100; ++i) {
        Point p = *rnd++;

        // Locate the point
        Delaunay::Locate_type lt;
        int li, lj;
        Cell_handle c = T.locate(p, lt, li, lj);
        if (lt == Delaunay::VERTEX)
            continue; // Point already exists

        // Get the cells that conflict with p in a vector V,
        // and a facet on the boundary of this hole in f.
        std::vector<Cell_handle> V;
        Facet f;

        T.find_conflicts(p, c,
                        CGAL::Oneset_iterator<Facet>(f), // Get one boundary
                        facet
                        std::back_inserter(V));          // Conflict cells
        in V

        if ((V.size() & 1) == 0) // Even number of conflict cells ?
            T.insert_in_hole(p, V.begin(), V.end(), f.first, f.second);
    }

    std::cout << "Final triangulation has " << T.number_of_vertices()
               << " vertices." << std::endl;

    return 0;
}

```

File: examples/Triangulation_3/find_conflicts_3.cpp

37.5.6 Regular Triangulation

This example shows the building of a regular triangulation. In this triangulation, points have an associated weight, and some points can be hidden and do not result in vertices in the triangulation. Another difference is that a specific traits class has to be used (at least at the moment).

```
#include <CGAL/Exact_predicates_inexact_constructions_kernel.h>
#include <CGAL/Regular_triangulation_3.h>
#include <CGAL/Regular_triangulation_euclidean_traits_3.h>
#include <cassert>
#include <vector>

typedef CGAL::Exact_predicates_inexact_constructions_kernel K;

typedef CGAL::Regular_triangulation_euclidean_traits_3<K> Traits;

typedef Traits::RT Weight;
typedef Traits::Bare_point Point;
typedef Traits::Weighted_point Weighted_point;

typedef CGAL::Regular_triangulation_3<Traits> Rt;

typedef Rt::Vertex_iterator Vertex_iterator;
typedef Rt::Vertex_handle Vertex_handle;

int main()
{
    // generate points on a 3D grid
    std::vector<Weighted_point> P;

    int number_of_points = 0;

    for (int z=0 ; z<5 ; z++)
        for (int y=0 ; y<5 ; y++)
            for (int x=0 ; x<5 ; x++) {
                Point p(x, y, z);
                Weight w = (x+y-z*y*x)*2.0; // let's say this is the weight.
                P.push_back(Weighted_point(p, w));
                ++number_of_points;
            }

    Rt T;

    // insert all points in a row (this is faster than one insert() at a time).
    T.insert (P.begin(), P.end());

    assert( T.is_valid() );
}
```

```

assert( T.dimension() == 3 );

std::cout << "Number of vertices : " << T.number_of_vertices() <<
    std::endl;

// removal of all vertices
int count = 0;
while (T.number_of_vertices() > 0) {
    T.remove (T.finite_vertices_begin());
    ++count;
}

assert( count == number_of_points );

return 0;
}

```

File: examples/Triangulation_3/regular_3.cpp

37.6 Complexity and Performance

In 3D, the worst case complexity of a triangulation is quadratic in the number of points. For Delaunay triangulations, this bound is reached in cases such as points equally distributed on two non-coplanar lines. However, the good news is that, in many cases, the complexity of a Delaunay triangulation is linear or close to linear in the number of points. Several articles [Dwy89, Eri02, AAD07, AB03, ABL03] have proved such good complexity bounds for specific point distributions, such as points distributed on surfaces under some conditions.

37.6.1 Running Time

There are several algorithms provided in this package. We will focus here on the following ones and give practical numbers on their efficiency :

- construction of a triangulation from a range of points,
- location of a point (using the *locate* function),
- removal of a vertex (using the *remove* function).

We will use the following types of triangulations, using *Exact_predicates_inexact_constructions_kernel* as geometric traits (combined with *Regular_triangulation_euclidean_traits_3* in the weighted case) :

- **Delaunay** : *Delaunay_triangulation_3*
- **Delaunay - Fast location** : *Delaunay_triangulation_3* with *Fast_location*
- **Regular** : *Regular_triangulation_3* (default setting : memorize hidden points)
- **Regular - No hidden points** : *Regular_triangulation_3* with hidden points discarded (using *Triangulation_cell_base_3* instead of *Regular_triangulation_cell_base_3*).

Figure 37.6 shows, for all these types of triangulations, the times in seconds taken to build a triangulation from a given number of points, then the average time to perform one point location in triangulations of various sizes, and the average time to perform one vertex removal (which is largely independent on the size of the triangulation).

The data sets used here are points randomly distributed in the unit cube (the coordinates are generated using the `drand48` C function). In the weighted case, the weights are all zero, which means that there are actually no hidden points during execution.

The measurements have been performed using CGAL 3.6, using the GNU C++ compiler version 4.3.2, under Linux (Fedora 10 distribution), with the compilation options `-O3 -DCGAL_NDEBUG`. The computer used was equipped with a 64bit Intel Xeon 3GHz processor and 32GB of RAM (a recent desktop machine as of 2009).

	Delaunay	Delaunay Fast location	Regular	Regular No hidden points
Construction from 10^2 points	0.00054	0.000576	0.000948	0.000955
Construction from 10^3 points	0.00724	0.00748	0.0114	0.0111
Construction from 10^4 points	0.0785	0.0838	0.122	0.117
Construction from 10^5 points	0.827	0.878	1.25	1.19
Construction from 10^6 points	8.5	9.07	12.6	12.2
Construction from 10^7 points	87.4	92.5	129	125
Point location in 10^2 points	9.93e-07	1.06e-06	7.19e-06	6.99e-06
Point location in 10^3 points	2.25e-06	1.93e-06	1.73e-05	1.76e-05
Point location in 10^4 points	4.79e-06	3.09e-06	3.96e-05	3.76e-05
Point location in 10^5 points	2.98e-05	6.12e-06	1.06e-04	1.06e-04
Point location in 10^6 points	1e-04	9.65e-06	2.7e-04	2.67e-04
Point location in 10^7 points	2.59e-04	1.33e-05	6.25e-04	6.25e-04
Vertex removal	1e-04	1.03e-04	1.42e-04	1.38e-04

Figure 37.6: Running times in seconds for algorithms on 3D triangulations.

More benchmarks comparing CGAL to other software can be found in [LS05].

37.6.2 Memory Usage

We give here some indication about the memory usage of the triangulations. Those structures being intensively based on pointers, the size almost doubles on 64bit platforms compared to 32bit.

The size also depends on the size of the point type which is copied in the vertices (hence on the kernel). Obviously, any user data added to vertices and cells also affect the memory used.

More specifically, the memory space used to store a triangulation is first a function of the size of its *Vertex* and *Cell* types times their numbers (and for volumic distribution, one sees about 6.7 times more cells than vertices). However, these are stored in memory using *Compact_container*, which allocates them in lists of blocks of growing size, and this requires some additional overhead for bookkeeping. Moreover, memory is only released to the system when clearing or destroying the triangulation. This can be important for algorithms like simplifications of data sets which will produce fragmented memory usage (doing fresh copies of the data structures are one way out in such cases). The asymptotic memory overhead of *Compact_container* for its internal bookkeeping is otherwise on the order of $O(\sqrt{n})$.

Figure 37.7 shows the number of bytes used per points, as measured empirically using *Memory_sizer* for large triangulations (10^6 random points).

	Delaunay	Delaunay Fast location	Regular	Regular No hidden points
32bit	274	291	336	282
64bit	519	553	635	527

Figure 37.7: Memory usage in bytes per point for large data sets.

37.6.3 Variability Depending on the Data Sets and the Kernel

Besides the complexity of the Delaunay triangulation that varies with the distribution of the points, another critical aspect affects the efficiency : the degeneracy of the data sets. These algorithms are quite sensitive to numerical accuracy and it is important to run them using exact predicates.

Using a kernel with no exact predicates will quickly lead to crashes or infinite loops once they are executed on non-random data sets. More precisely, problems appear with data sets which contain (nearly) degenerate cases for the *orientation* and *side_of_oriented_sphere* predicates, namely when there are (nearly) coplanar or (nearly) cospherical points. This unfortunately happens often in practice with data coming from various kinds of scanners or other automatic acquisition devices.

Using an inexact kernel such as *Simple_cartesian<double>* would lead to optimal performance, which is only about 30% better than *Exact_predicates_inexact_constructions_kernel*. The latter is strongly recommended since it takes care about potential robustness issues. The former can be used for benchmarking purposes mostly, or when you really know that your data sets won't exhibit any robustness issue.

Exact predicates take more time to compute when they hit (nearly) degenerate cases. Depending on the data set, this can have a visible impact on the overall performance of the algorithm or not.

Sometimes you need exact constructions as well, so *Exact_predicates_exact_constructions_kernel* is a must. This is the case for example when you need the *dual* functions to be exact, or when your input is stored in points of such a kernel for other reasons (because it is the output of another algorithm which has this requirement, for example). This will slow down the computations by a factor of 4 to 5 at least, and it can be much more.

Figure 37.8 gives more detailed timings about various kernels on the following data sets : random points in a cube, random points on the surface of an ellipsoid, points scanned on the surface of a Buddha statue, points on a molecular surface, and points scanned on a dryer handle. See Figure 37.9 for pictures of the last 3 objects, which respectively illustrate volumic data, surfacic data, and data with many degenerate cases. This last data set exhibits an infinite loop with an inexact kernel, and of course we are not sure whether what is computed for the other data sets with this inexact kernel is a Delaunay triangulation. General introductory information about these robustness issues can be found in [KMP⁺08]. More benchmarks around this issue can also be found in [DP03].

	Random	Ellipsoid	Buddha	Molecule	Dryer Handle
#points	100000	100000	542548	525296	49787
<i>Simple_cartesian<double></i>	0.69	0.627	4.21	3.8	∞-loop
<i>Exact_predicates_inexact_constructions_kernel</i>	0.824	0.749	4.99	4.64	1.68

37.7 Design and Implementation History

Monique Teillaud started to work on the 3D triangulation packages in 1997, following the design of the 2D triangulation packages. The notions of degenerate dimensions and infinite vertex were formalized [Tei99] and induced changes in the 2D triangulation packages. The packages were first released in CGAL 2.1. They contained basic functionalities on triangulations, Delaunay triangulations, regular triangulations.

A first version of removal of a vertex from a Delaunay triangulation was released in CGAL 2.2. However, this removal became really robust only in CGAL 2.3, after some research that allowed to deal with degenerate cases quite easily [DT03]. Andreas Fabri implemented this revised version of the removal, and a faster removal algorithm for CGAL 3.0.

The latter algorithm was proposed by Mariette Yvinec, who contributed in several ways to the package, first since she was maintaining the close 2D triangulation package and participated in many discussions, she also wrote the traits classes for regular triangulations.

In 2000, Sylvain Pion started working on these packages. He improved the efficiency of triangulations in CGAL 2.3 and 2.4 in several ways [BDP⁺02]: he implemented the Delaunay hierarchy [Dev02] in 2.3, he improved the memory footprint in 2.4 and 3.0, he also performed work on arithmetic filters [DP03] (see *Filtered_kernel*) to improve the speed of triangulations. He changed the design in CGAL 3.0, allowing users to add handles in their own vertices and cells.

Olivier Devillers, co-author of preliminary versions of the CGAL 2d triangulations, participated in many discussions, in particular about the perturbations, and more concretely in the implementation of the Delaunay hierarchy.

In 2005, Christophe Delage implemented the vertex removal function for regular triangulations, using the symbolic perturbation proposed in [DT06], which allowed to release this functionality in CGAL 3.2.

In 2006, Nico Kruithof wrote the *Triangulation_simplex_3* class that can store simplices of any dimension and improved the internal organization of the code.

As of March 2007, Christophe Delage made the iterator range insert methods and constructors use *spatial_sort* to improve efficiency.

In 2008, Camille Wormser added a few more iterators in the package that were integrated in release 3.4.

In 2009, Sylvain Pion simplified the design of the Delaunay hierarchy so that it became the simple *Fast_Location* policy in release 3.6.

In 2010, Pedro de Castro and Olivier Devillers added the point displacement.

The authors wish to thank Lutz Kettner for inspiring discussions about the design of CGAL. Jean-Daniel Boissonnat is also acknowledged [BDTY00].

3D Triangulations

Reference Manual

Sylvain Pion and Monique Teillaud

A three-dimensional triangulation is a three-dimensional simplicial complex, pure connected and without singularities [BY98]. Its cells (3-faces) are such that two cells either do not intersect or share a common facet (2-face), edge (1-face) or vertex (0-face).

The basic 3D-triangulation class of CGAL is primarily designed to represent the triangulations of a set of points A in \mathbb{R}^3 . It can be viewed as a partition of the convex hull of A into tetrahedra whose vertices are the points of A . Together with the unbounded cell having the convex hull boundary as its frontier, the triangulation forms a partition of \mathbb{R}^3 .

In order to deal only with tetrahedra, which is convenient for many applications, the unbounded cell can be subdivided into tetrahedra by considering that each convex hull facet is incident to an *infinite cell* having as fourth vertex an auxiliary vertex called the *infinite vertex*. In that way, each facet is incident to exactly two cells and special cases at the boundary of the convex hull are simple to deal with.

A triangulation is a collection of vertices and cells that are linked together through incidence and adjacency relations. Each cell gives access to its four incident vertices and to its four adjacent cells. Each vertex gives access to one of its incident cells.

The four vertices of a cell are indexed with 0, 1, 2 and 3 in positive orientation, the positive orientation being defined by the orientation of the underlying Euclidean space \mathbb{R}^3 . The neighbors of a cell are also indexed with 0, 1, 2, 3 in such a way that the neighbor indexed by i is opposite to the vertex with the same index. See Figure 37.1.

CGAL::Triangulation_3<TriangulationTraits_3,TriangulationDataStructure_3>

Definition

The class *Triangulation_3* represents a 3-dimensional tetrahedralization of points.

```
#include <CGAL/Triangulation_3.h>
```

Parameters

The first template argument must be a model of the *TriangulationTraits_3* concept.

The second template argument must be a model of the *TriangulationDataStructure_3* concept. It has the default value *Triangulation_data_structure_3< Triangulation_vertex_base_3<TriangulationTraits_3>,Triangulation_cell_base_3<TriangulationTraits_3> >*.

Inherits From

Triangulation_utils_3

Types

The class *Triangulation_3* defines the following types:

<code>typedef TriangulationDataStructure_3</code>	<code>Triangulation_data_structure;</code>
<code>typedef TriangulationTraits_3</code>	<code>Geom_traits;</code>
<code>typedef TriangulationTraits_3::Point_3</code>	<code>Point;</code>
<code>typedef TriangulationTraits_3::Segment_3</code>	<code>Segment;</code>
<code>typedef TriangulationTraits_3::Triangle_3</code>	<code>Triangle;</code>
<code>typedef TriangulationTraits_3::Tetrahedron_3</code>	<code>Tetrahedron;</code>

Only vertices (0-faces) and cells (3-faces) are stored. Edges (1-faces) and facets (2-faces) are not explicitly represented and thus there are no corresponding classes (see Section 37.1).

<code>typedef TriangulationDataStructure_3::Vertex</code>	<code>Vertex;</code>
<code>typedef TriangulationDataStructure_3::Cell</code>	<code>Cell;</code>
<code>typedef TriangulationDataStructure_3::Facet</code>	<code>Facet;</code>
<code>typedef TriangulationDataStructure_3::Edge</code>	<code>Edge;</code>

The vertices and faces of the triangulations are accessed through *handles*, *iterators* and *circulators*. A handle is a model of the *Handle* concept, and supports the two dereference operators *operator** and *operator->*. A circulator is a model of the concept *Circulator*. Iterators and circulators are bidirectional and non-mutable. The edges and facets of the triangulation can also be visited through iterators and circulators which are bidirectional and non-mutable.

Iterators and circulators are convertible to the corresponding handles, thus the user can pass them directly as arguments to the functions.

<i>typedef TriangulationDataStructure_3::Vertex_handle</i>	<i>Vertex_handle;</i>	handle to a vertex
<i>typedef TriangulationDataStructure_3::Cell_handle</i>	<i>Cell_handle;</i>	handle to a cell
<i>typedef Triangulation_simplex_3<Self></i>	<i>Simplex;</i>	Reference to a simplex (vertex, edge, facet or cell) of the triangulation
<i>typedef TriangulationDataStructure_3::size_type</i>	<i>size_type;</i>	Size type (an unsigned integral type)
<i>typedef TriangulationDataStructure_3::difference_type</i>	<i>difference_type;</i>	Difference type (a signed integral type)
<i>typedef TriangulationDataStructure_3::Cell_iterator</i>	<i>All_cells_iterator;</i>	iterator over cells
<i>typedef TriangulationDataStructure_3::Facet_iterator</i>	<i>All_facets_iterator;</i>	iterator over facets
<i>typedef TriangulationDataStructure_3::Edge_iterator</i>	<i>All_edges_iterator;</i>	iterator over edges
<i>typedef TriangulationDataStructure_3::Vertex_iterator</i>	<i>All_vertices_iterator;</i>	iterator over vertices
<i>Triangulation_3<TriangulationTraits_3,TriangulationDataStructure_3>:: Finite_cells_iterator</i>		iterator over finite cells
<i>Triangulation_3<TriangulationTraits_3,TriangulationDataStructure_3>:: Finite_facets_iterator</i>		iterator over finite facets
<i>Triangulation_3<TriangulationTraits_3,TriangulationDataStructure_3>:: Finite_edges_iterator</i>		iterator over finite edges
<i>Triangulation_3<TriangulationTraits_3,TriangulationDataStructure_3>:: Finite_vertices_iterator</i>		iterator over finite vertices
<i>Triangulation_3<TriangulationTraits_3,TriangulationDataStructure_3>:: Point_iterator</i>		iterator over the points corresponding to the finite vertices of the triangulation.
<i>typedef TriangulationDataStructure_3::Cell_circulator</i>	<i>Cell_circulator;</i>	circulator over all cells incident to a given edge
<i>typedef TriangulationDataStructure_3::Facet_circulator</i>	<i>Facet_circulator;</i>	circulator over all facets incident to a given edge

The triangulation class also defines the following enum type to specify which case occurs when locating a point in the triangulation.

```
enum Locate_type { VERTEX=0,
                  EDGE,
                  FACET,
                  CELL,
                  OUTSIDE_CONVEX_HULL,
                  OUTSIDE_AFFINE_HULL }
```

Creation

```
Triangulation_3<TriangulationTraits_3,TriangulationDataStructure_3> t( TriangulationTraits_3 traits =
TriangulationTraits_3())
```

Introduces a triangulation t having only one vertex which is the infinite vertex.

```
Triangulation_3<TriangulationTraits_3,TriangulationDataStructure_3> t( Triangulation_3 tr);
```

Copy constructor. All vertices and faces are duplicated.

```
template < class InputIterator>
Triangulation_3<TriangulationTraits_3,TriangulationDataStructure_3> t( InputIterator first,
                                                                    InputIterator last,
                                                                    TriangulationTraits_3 traits =
TriangulationTraits_3())
```

Equivalent to constructing an empty triangulation with the optional traits class argument and calling *insert(first,last)*.

Assignment

```
Triangulation_3 & t = Triangulation_3 tr
```

The triangulation tr is duplicated, and modifying the copy after the duplication does not modify the original. The previous triangulation held by t is deleted.

```
void t.swap( Triangulation_3 & tr)
```

The triangulations tr and t are swapped. *t.swap(tr)* should be preferred to $t = tr$ or to $t(tr)$ if tr is deleted after that. Indeed, there is no copy of cells and vertices, thus this method runs in constant time.

```
void t.clear() Deletes all finite vertices and all cells of t.
```

```
template < class GT, class Tds1, class Tds2 >
```

bool *Triangulation_3*<*GT*, *Tds1*> *t1* == *Triangulation_3*<*GT*, *Tds2*> *t2*

Equality operator. Returns true iff there exist a bijection between the vertices of *t1* and those of *t2* and a bijection between the cells of *t1* and those of *t2*, which preserve the geometry of the triangulation, that is, the points of each corresponding pair of vertices are equal, and the tetrahedra corresponding to each pair of cells are equal (up to a permutation of their vertices).

template < *class GT*, *class Tds1*, *class Tds2* >

bool *Triangulation_3*<*GT*, *Tds1*> *t1* != *Triangulation_3*<*GT*, *Tds2*> *t2*

The opposite of *operator==*.

Access Functions

TriangulationTraits_3 *t.geom_traits()* Returns a const reference to the geometric traits object.

TriangulationDataStructure_3 *t.tds()* Returns a const reference to the triangulation data structure.

————— *advanced* —————

Non const access

The responsibility of keeping a valid triangulation belongs to the user when using advanced operations allowing a direct manipulation of the *tds*.

TriangulationDataStructure_3& *t.tds()* Returns a reference to the triangulation data structure.

This method is mainly a help for users implementing their own triangulation algorithms.

————— *advanced* —————

int *t.dimension()* Returns the dimension of the affine hull.
size_type *t.number_of_vertices()* Returns the number of finite vertices.
size_type *t.number_of_cells()* Returns the number of cells or 0 if *t.dimension()* < 3.

Vertex_handle *t.infinite_vertex()* Returns the infinite vertex.
Cell_handle *t.infinite_cell()* Returns a cell incident to the infinite vertex.

Non-constant-time access functions

As previously said, the triangulation is a collection of cells that are either infinite or represent a finite tetrahedra, where an infinite cell is a cell incident to the infinite vertex. Similarly we call an edge (resp. facet) *infinite* if it is incident to the infinite vertex.

size_type *t.number_of_facets()* The number of facets. Returns 0 if *t.dimension()* < 2.
size_type *t.number_of_edges()* The number of edges. Returns 0 if *t.dimension()* < 1.

size_type *t.number_of_finite_cells()* The number of finite cells. Returns 0 if *t.dimension()* < 3.
size_type *t.number_of_finite_facets()* The number of finite facets. Returns 0 if *t.dimension()* < 2.

size_type *t.number_of_finite_edges()* The number of finite edges. Returns 0 if *t.dimension()* < 1.

Geometric access functions

Tetrahedron *t.tetrahedron(Cell_handle c)*

Returns the tetrahedron formed by the four vertices of *c*.
Precondition: *t.dimension()* = 3 and the cell is finite.

Triangle *t.triangle(Cell_handle c, int i)*

Returns the triangle formed by the three vertices of facet (c, i) . The triangle is oriented so that its normal points to the inside of cell *c*.
Precondition: *t.dimension()* ≥ 2 and $i \in \{0, 1, 2, 3\}$ in dimension 3, $i = 3$ in dimension 2, and the facet is finite.

Triangle *t.triangle(Facet f)*

Same as the previous method for facet *f*.
Precondition: *t.dimension()* ≥ 2 and the facet is finite.

Segment *t.segment(Edge e)*

Returns the line segment formed by the vertices of *e*.
Precondition: *t.dimension()* ≥ 1 and *e* is finite.

Segment *t.segment(Cell_handle c, int i, int j)*

Same as the previous method for edge (c, i, j) .
Precondition: As above and $i \neq j$. Moreover $i, j \in \{0, 1, 2, 3\}$ in dimension 3, $i, j \in \{0, 1, 2\}$ in dimension 2, $i, j \in \{0, 1\}$ in dimension 1, and the edge is finite.

Point *t.point(Cell_handle c, int i)*

Returns the point given by vertex *i* of cell *c*.
Precondition: *t.dimension()* ≥ 0 and $i \in \{0, 1, 2, 3\}$ in dimension 3, $i \in \{0, 1, 2\}$ in dimension 2, $i \in \{0, 1\}$ in dimension 1, $i = 0$ in dimension 0, and the vertex is finite.

Point *t.point(Vertex_handle v)*

Same as the previous method for vertex *v*.
Precondition: *t.dimension()* ≥ 0 and the vertex is finite.

Tests for Finite and Infinite Vertices and Faces

bool *t.is_infinite(Vertex_handle v)*

true, iff vertex *v* is the infinite vertex.

bool *t.is_infinite(Cell_handle c)*

true, iff *c* is incident to the infinite vertex.
Precondition: *t.dimension()* = 3.

bool *t.is_infinite(Cell_handle c, int i)*

true, iff the facet *i* of cell *c* is incident to the infinite vertex.
Precondition: *t.dimension()* ≥ 2 and $i \in \{0, 1, 2, 3\}$ in dimension 3, $i = 3$ in dimension 2.

bool *t.is_infinite(Facet f)*

true iff facet *f* is incident to the infinite vertex.
Precondition: t.dimension() ≥ 2.

bool *t.is_infinite(Cell_handle c, int i, int j)*

true, iff the edge (*i,j*) of cell *c* is incident to the infinite vertex.
Precondition: t.dimension() ≥ 1 and i ≠ j. Moreover i, j ∈ {0,1,2,3} in dimension 3, i, j ∈ {0,1,2} in dimension 2, i, j ∈ {0,1} in dimension 1.

bool *t.is_infinite(Edge e)*

true iff edge *e* is incident to the infinite vertex.
Precondition: t.dimension() ≥ 1.

Queries

bool *t.is_vertex(Point p, Vertex_handle & v)*

Tests whether *p* is a vertex of *t* by locating *p* in the triangulation. If *p* is found, the associated vertex *v* is given.

bool *t.is_vertex(Vertex_handle v)*

Tests whether *v* is a vertex of *t*.

bool *t.is_edge(Vertex_handle u, Vertex_handle v, Cell_handle & c, int & i, int & j)*

Tests whether (*u,v*) is an edge of *t*. If the edge is found, it gives a cell *c* having this edge and the indices *i* and *j* of the vertices *u* and *v* in *c*, in this order.
Precondition: u and v are vertices of t.

bool *t.is_facet(Vertex_handle u,*
 Vertex_handle v,
 Vertex_handle w,
 Cell_handle & c,
 int & i,
 int & j,
 int & k)

Tests whether (*u,v,w*) is a facet of *t*. If the facet is found, it computes a cell *c* having this facet and the indices *i, j* and *k* of the vertices *u, v* and *w* in *c*, in this order.
Precondition: u, v and w are vertices of t.

bool *t.is_cell(Cell_handle c)*

Tests whether *c* is a cell of *t*.

```

bool      t.is_cell( Vertex_handle u,
                    Vertex_handle v,
                    Vertex_handle w,
                    Vertex_handle x,
                    Cell_handle & c,
                    int & i,
                    int & j,
                    int & k,
                    int & l)

```

Tests whether (u,v,w,x) is a cell of t . If the cell c is found, the method computes the indices i, j, k and l of the vertices u, v, w and x in c , in this order.
Precondition: u, v, w and x are vertices of t .

```

bool      t.is_cell( Vertex_handle u,
                    Vertex_handle v,
                    Vertex_handle w,
                    Vertex_handle x,
                    Cell_handle & c)

```

Tests whether (u,v,w,x) is a cell of t and computes this cell c .
Precondition: u, v, w and x are vertices of t .

There is a method *has_vertex* in the cell class. The analogous methods for facets are defined here.

```

bool      t.has_vertex( Facet f, Vertex_handle v, int & j)

```

If v is a vertex of f , then j is the index of v in the cell $f.first$, and the method returns *true*.
Precondition: $t.dimension()=3$

```

bool      t.has_vertex( Cell_handle c, int i, Vertex_handle v, int & j)

```

Same for facet (c,i) . Computes the index j of v in c .

```

bool      t.has_vertex( Facet f, Vertex_handle v)

```

```

bool      t.has_vertex( Cell_handle c, int i, Vertex_handle v)

```

Same as the first two methods, but these two methods do not return the index of the vertex.

The following three methods test whether two facets have the same vertices.

```

bool      t.are_equal( Cell_handle c, int i, Cell_handle n, int j)

```

```

bool      t.are_equal( Facet f, Facet g)

```

```

bool      t.are_equal( Facet f, Cell_handle n, int j)

```

For these three methods:
Precondition: $t.dimension()=3$.

Point location

The class *Triangulation_3*<*TriangulationTraits_3*,*TriangulationDataStructure_3*> provides two functions to locate a given point with respect to a triangulation. It provides also functions to test if a given point is inside a finite face or not. Note that the class *Delaunay-triangulation_3* also provides a *nearest_vertex()* function.

Cell_handle *t.locate(Point query, Cell_handle start = Cell_handle())*

If the point *query* lies inside the convex hull of the points, the cell that contains the query in its interior is returned. If *query* lies on a facet, an edge or on a vertex, one of the cells having *query* on its boundary is returned.

If the point *query* lies outside the convex hull of the points, an infinite cell with vertices $\{p, q, r, \infty\}$ is returned such that the tetrahedron $(p, q, r, query)$ is positively oriented (the rest of the triangulation lies on the other side of facet (p, q, r)).

Note that *locate* works even in degenerate dimensions: in dimension 2 (resp. 1, 0) the *Cell_handle* returned is the one that represents the facet (resp. edge, vertex) containing the query point.

The optional argument *start* is used as a starting place for the search.

Cell_handle *t.locate(Point query, Vertex_handle hint)*

Same as above but uses *hint* as the starting place for the search.

Cell_handle *t.locate(Point query, Locate_type & lt, int & li, int & lj, Cell_handle start = Cell_handle())*

If *query* lies inside the affine hull of the points, the *k*-face (finite or infinite) that contains *query* in its interior is returned, by means of the cell returned together with *lt*, which is set to the locate type of the query (*VERTEX*, *EDGE*, *FACET*, *CELL*, or *OUTSIDE_CONVEX_HULL* if the cell is infinite and *query* lies strictly in it) and two indices *li* and *lj* that specify the *k*-face of the cell containing *query*.

If the *k*-face is a cell, *li* and *lj* have no meaning; if it is a facet (resp. vertex), *li* gives the index of the facet (resp. vertex) and *lj* has no meaning; if it is an edge, *li* and *lj* give the indices of its vertices.

If the point *query* lies outside the affine hull of the points, which can happen in case of degenerate dimensions, *lt* is set to *OUTSIDE_AFFINE_HULL*, and the cell returned has no meaning. As a particular case, if there is no finite vertex yet in the triangulation, *lt* is set to *OUTSIDE_AFFINE_HULL* and *locate* returns the default constructed handle.

The optional argument *start* is used as a starting place for the search.

Cell_handle *t.locate(Point query, Locate_type & lt, int & li, int & lj, Vertex_handle hint)*

Same as above but uses *hint* as the starting place for the search.

Bounded_side *t.side_of_cell(Point p, Cell_handle c, Locate_type & lt, int & li, int & lj)*

Returns a value indicating on which side of the oriented boundary of *c* the point *p* lies. More precisely, it returns:

- *ON_BOUNDED_SIDE* if *p* is inside the cell. For an infinite cell this means that *p* lies strictly in the half space limited by its finite facet and not containing any other point of the triangulation.
- *ON_BOUNDARY* if *p* on the boundary of the cell. For an infinite cell this means that *p* lies on the *finite* facet. Then *lt* together with *li* and *lj* give the precise location on the boundary. (See the descriptions of the *locate* methods.)
- *ON_UNBOUNDED_SIDE* if *p* lies outside the cell. For an infinite cell this means that *p* does not satisfy either of the two previous conditions.

Precondition: t.dimension() = 3

Bounded_side *t.side_of_facet(Point p, Facet f, Locate_type & lt, int & li, int & lj)*

Returns a value indicating on which side of the oriented boundary of *f* the point *p* lies:

- *ON_BOUNDED_SIDE* if *p* is inside the facet. For an infinite facet this means that *p* lies strictly in the half plane limited by its finite edge and not containing any other point of the triangulation .
- *ON_BOUNDARY* if *p* is on the boundary of the facet. For an infinite facet this means that *p* lies on the finite edge. *lt*, *li* and *lj* give the precise location of *p* on the boundary of the facet. *li* and *lj* refer to indices in the degenerate cell *c* representing *f*.
- *ON_UNBOUNDED_SIDE* if *p* lies outside the facet. For an infinite facet this means that *p* does not satisfy either of the two previous conditions.

Precondition: t.dimension() = 2 and p lies in the plane containing the triangulation. f.second = 3 (in dimension 2 there is only one facet per cell).

Bounded_side *t.side_of_facet(Point p, Cell_handle c, Locate_type & lt, int & li, int & lj)*

Same as the previous method for the facet (*c*,3).

Bounded_side *t.side_of_edge(Point p, Edge e, Locate_type & lt, int & li)*

Returns a value indicating on which side of the oriented boundary of *e* the point *p* lies:

- *ON_BOUNDED_SIDE* if *p* is inside the edge. For an infinite edge this means that *p* lies in the half line defined by the vertex and not containing any other point of the triangulation.
- *ON_BOUNDARY* if *p* equals one of the vertices, *li* give the index of the vertex in the cell storing *e*
- *ON_UNBOUNDED_SIDE* if *p* lies outside the edge. For an infinite edge this means that *p* lies on the other half line, which contains the other points of the triangulation.

Precondition: t.dimension() = 1 and p is collinear with the points of the triangulation. e.second = 0 and e.third = 1 (in dimension 1 there is only one edge per cell).

Bounded_side *t.side_of_edge(Point p, Cell_handle c, Locate_type & lt, int & li)*

Same as the previous method for edge (*c*,0,1).

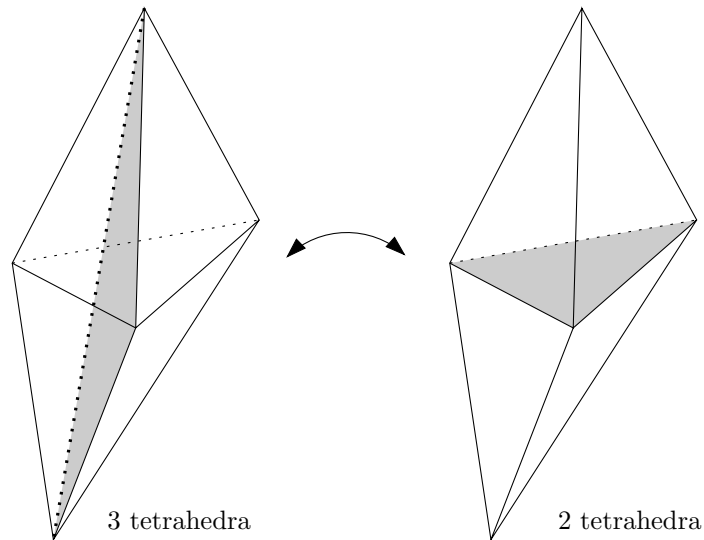

Figure 37.10: Flips.

Flips

Two kinds of flips exist for a three-dimensional triangulation. They are reciprocal. To be flipped, an edge must be incident to three tetrahedra. During the flip, these three tetrahedra disappear and two tetrahedra appear. Figure 37.10(left) shows the edge that is flipped as bold dashed, and one of its three incident facets is shaded. On the right, the facet shared by the two new tetrahedra is shaded.

Flips are possible only under the following conditions:

- the edge or facet to be flipped is not on the boundary of the convex hull of the triangulation
- the five points involved are in convex position.

The following methods guarantee the validity of the resulting 3D triangulation.

Flips for a 2d triangulation are not implemented yet

```
bool      t.flip( Edge e)
bool      t.flip( Cell_handle c, int i, int j)
```

Before flipping, these methods check that edge $e=(c,i,j)$ is flippable (which is quite expensive). They return *false* or *true* according to this test.

```
void      t.flip_flippable( Edge e)
void      t.flip_flippable( Cell_handle c, int i, int j)
```

Should be preferred to the previous methods when the edge is known to be flippable.

Precondition: The edge is flippable.

```
bool      t.flip( Facet f)
bool      t.flip( Cell_handle c, int i)
```

Before flipping, these methods check that facet $f=(c,i)$ is flippable (which is quite expensive). They return *false* or *true* according to this test.

```
void      t.flip_flippable( Facet f)
void      t.flip_flippable( Cell_handle c, int i)
```

Should be preferred to the previous methods when the facet is known to be flippable.

Precondition: The facet is flippable.

Insertions

The following operations are guaranteed to lead to a valid triangulation when they are applied on a valid triangulation.

```
Vertex_handle  t.insert( Point p, Cell_handle start = Cell_handle())
```

Inserts point p in the triangulation and returns the corresponding vertex.

If point p coincides with an already existing vertex, this vertex is returned and the triangulation remains unchanged.

If point p lies in the convex hull of the points, it is added naturally: if it lies inside a cell, the cell is split into four cells, if it lies on a facet, the two incident cells are split into three cells, if it lies on an edge, all the cells incident to this edge are split into two cells.

If point p is strictly outside the convex hull but in the affine hull, p is linked to all visible points on the convex hull to form the new triangulation. See Figure 37.11.

If point p is outside the affine hull of the points, p is linked to all the points, and the dimension of the triangulation is incremented. All the points now belong to the boundary of the convex hull, so, the infinite vertex is linked to all the points to triangulate the new infinite face. See Figure 37.12. The optional argument *start* is used as a starting place for the search.

```
Vertex_handle  t.insert( Point p, Vertex_handle hint)
```

Same as above but uses *hint* as the starting place for the search.

```
Vertex_handle  t.insert( Point p, Locate_type lt, Cell_handle loc, int li, int lj)
```

Inserts point p in the triangulation and returns the corresponding vertex. Similar to the above *insert()* function, but takes as additional parameter the return values of a previous location query. See description of *locate()* above.

```
template < class InputIterator >
std::ptrdiff_t  t.insert( InputIterator first, InputIterator last)
```

Inserts the points in the range $[first, last)$. Returns the number of inserted points. Note that this function is not guaranteed to insert the points following the order of *InputIterator*.

Precondition: The *value_type* of *first* and *last* is *Point*.

The previous methods are sufficient to build a whole triangulation. We also provide some other methods that can be used instead of *insert(p)* when the place where the new point p must be inserted is already known. They are also guaranteed to lead to a valid triangulation when they are applied on a valid triangulation.

Vertex_handle *t.insert_in_cell(Point p, Cell_handle c)*

Inserts point *p* in cell *c*. Cell *c* is split into 4 tetrahedra.
Precondition: *t.dimension()* = 3 and *p* lies strictly inside cell *c*.

Vertex_handle *t.insert_in_facet(Point p, Facet f)*

Inserts point *p* in facet *f*. In dimension 3, the 2 neighboring cells are split into 3 tetrahedra; in dimension 2, the facet is split into 3 triangles.
Precondition: *t.dimension()* ≥ 2 and *p* lies strictly inside face *f*.

Vertex_handle *t.insert_in_facet(Point p, Cell_handle c, int i)*

As above, insertion in facet *(c,i)*.
Precondition: As above and *i* ∈ {0,1,2,3} in dimension 3, *i* = 3 in dimension 2.

Vertex_handle *t.insert_in_edge(Point p, Edge e)*

Inserts *p* in edge *e*. In dimension 3, all the cells having this edge are split into 2 tetrahedra; in dimension 2, the 2 neighboring facets are split into 2 triangles; in dimension 1, the edge is split into 2 edges.
Precondition: *t.dimension()* ≥ 1 and *p* lies on edge *e*.

Vertex_handle *t.insert_in_edge(Point p, Cell_handle c, int i, int j)*

As above, inserts *p* in edge *(i,j)* of *c*.
Precondition: As above and *i* ≠ *j*. Moreover *i, j* ∈ {0,1,2,3} in dimension 3, *i, j* ∈ {0,1,2} in dimension 2, *i, j* ∈ {0,1} in dimension 1.

Vertex_handle *t.insert_outside_convex_hull(Point p, Cell_handle c)*

The cell *c* must be an infinite cell containing *p*.
Links *p* to all points in the triangulation that are visible from *p*. Updates consequently the infinite faces. See Figure 37.11.
Precondition: *t.dimension()* > 0, *c*, and the *k*-face represented by *c* is infinite and contains *t*.

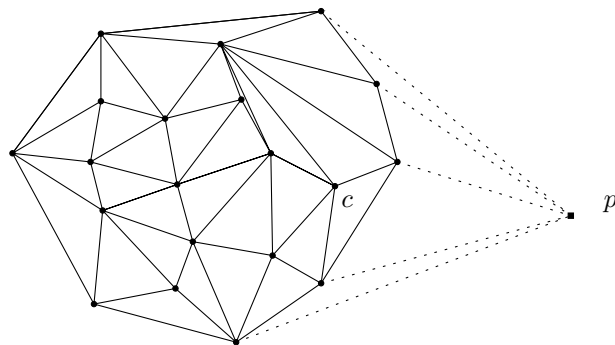

Figure 37.11: *insert_outside_convex_hull* (2-dimensional case).

Vertex_handle *t.insert_outside_affine_hull(Point p)*

p is linked to all the points, and the infinite vertex is linked to all the points (including *p*) to triangulate the new infinite face, so that all the points now belong to the boundary of the convex hull. See Figure 37.12.

This method can be used to insert the first point in an empty triangulation.

Precondition: *t.dimension()* < 3 and *p* lies outside the affine hull of the points.

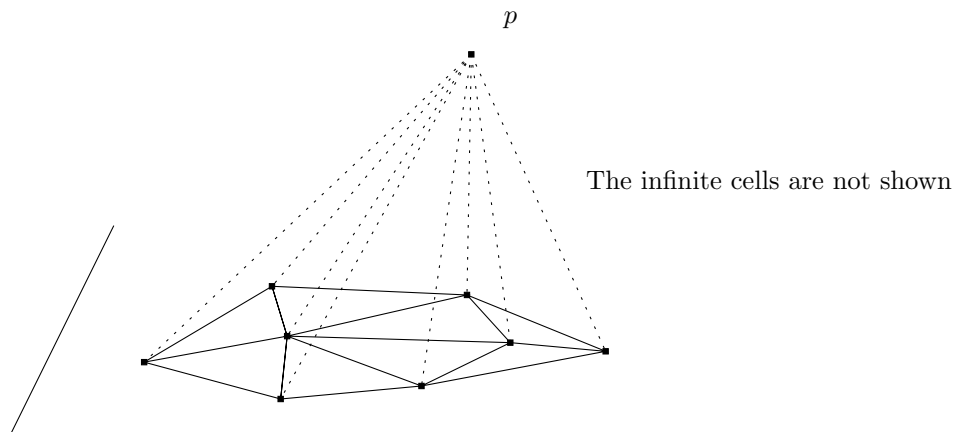

Figure 37.12: *insert_outside_affine_hull* (2-dimensional case).

template <class CellIt>

Vertex_handle *t.insert_in_hole(Point p, CellIt cell_begin, CellIt cell_end, Cell_handle begin, int i)*

Creates a new vertex by starring a hole. It takes an iterator range [*cell_begin*; *cell_end*] of *Cell_handles* which specifies a hole: a set of connected cells (resp. facets in dimension 2) which is star-shaped wrt *p*. (*begin*, *i*) is a facet (resp. an edge) on the boundary of the hole, that is, *begin* belongs to the set of cells (resp. facets) previously described, and *begin->neighbor(i)* does not. Then this function deletes all the cells (resp. facets) describing the hole, creates a new vertex *v*, and for each facet (resp. edge) on the boundary of the hole, creates a new cell (resp. facet) with *v* as vertex. Then *v->set_point(p)* is called and *v* is returned.

This operation is equivalent to calling *tds().insert_in_hole(cell_begin, cell_end, begin, i); v->set_point(p)*.

Precondition: *t.dimension()* ≥ 2, the set of cells (resp. facets in dimension 2) is connected, its boundary is connected, and *p* lies inside the hole, which is star-shaped wrt *p*.

template <class CellIt>

Vertex_handle *t.insert_in_hole(Point p,*
CellIt cell_begin,
CellIt cell_end,
Cell_handle begin,
int i,
Vertex_handle newv)

Same as above, except that *newv* will be used as the new vertex, which must have been allocated previously with e.g. *create_vertex*.

Traversal of the Triangulation

The triangulation class provides several iterators and circulators that allow one to traverse it (completely or partially).

Cell, Face, Edge and Vertex Iterators

The following iterators allow the user to visit cells, facets, edges and vertices of the triangulation. These iterators are non-mutable, bidirectional and their value types are respectively *Cell*, *Facet*, *Edge* and *Vertex*. They are all invalidated by any change in the triangulation.

<i>Finite_vertices_iterator</i>	<i>t.finite_vertices_begin()</i>	Starts at an arbitrary finite vertex. Then ++ and -- will iterate over finite vertices. Returns <i>finite_vertices_end()</i> when <i>t.number_of_vertices()</i> = 0.
<i>Finite_vertices_iterator</i>	<i>t.finite_vertices_end()</i>	Past-the-end iterator
<i>Finite_edges_iterator</i>	<i>t.finite_edges_begin()</i>	Starts at an arbitrary finite edge. Then ++ and -- will iterate over finite edges. Returns <i>finite_edges_end()</i> when <i>t.dimension()</i> < 1.
<i>Finite_edges_iterator</i>	<i>t.finite_edges_end()</i>	Past-the-end iterator
<i>Finite_facets_iterator</i>	<i>t.finite_facets_begin()</i>	Starts at an arbitrary finite facet. Then ++ and -- will iterate over finite facets. Returns <i>finite_facets_end()</i> when <i>t.dimension()</i> < 2.
<i>Finite_facets_iterator</i>	<i>t.finite_facets_end()</i>	Past-the-end iterator
<i>Finite_cells_iterator</i>	<i>t.finite_cells_begin()</i>	Starts at an arbitrary finite cell. Then ++ and -- will iterate over finite cells. Returns <i>finite_cells_end()</i> when <i>t.dimension()</i> < 3.
<i>Finite_cells_iterator</i>	<i>t.finite_cells_end()</i>	Past-the-end iterator
<i>All_vertices_iterator</i>	<i>t.all_vertices_begin()</i>	Starts at an arbitrary vertex. Iterates over all vertices (even the infinite one). Returns <i>vertices_end()</i> when <i>t.number_of_vertices()</i> = 0.
<i>All_vertices_iterator</i>	<i>t.all_vertices_end()</i>	Past-the-end iterator
<i>All_edges_iterator</i>	<i>t.all_edges_begin()</i>	Starts at an arbitrary edge. Iterates over all edges (even infinite ones). Returns <i>edges_end()</i> when <i>t.dimension()</i> < 1.
<i>All_edges_iterator</i>	<i>t.all_edges_end()</i>	Past-the-end iterator
<i>All_facets_iterator</i>	<i>t.all_facets_begin()</i>	Starts at an arbitrary facet. Iterates over all facets (even infinite ones). Returns <i>facets_end()</i> when <i>t.dimension()</i> < 2.
<i>All_facets_iterator</i>	<i>t.all_facets_end()</i>	Past-the-end iterator
<i>All_cells_iterator</i>	<i>t.all_cells_begin()</i>	Starts at an arbitrary cell. Iterates over all cells (even infinite ones). Returns <i>cells_end()</i> when <i>t.dimension()</i> < 3.
<i>All_cells_iterator</i>	<i>t.all_cells_end()</i>	Past-the-end iterator
<i>Point_iterator</i>	<i>t.points_begin()</i>	Iterates over the points of the triangulation.
<i>Point_iterator</i>	<i>t.points_end()</i>	Past-the-end iterator

Cell and Facet Circulators

The following circulators respectively visit all cells or all facets incident to a given edge. They are non-mutable and bidirectional. They are invalidated by any modification of one of the cells traversed.

<i>Cell_circulator</i>	<i>t.incident_cells(Edge e)</i>	Starts at an arbitrary cell incident to <i>e</i> . Precondition: <i>t.dimension() = 3</i> .
<i>Cell_circulator</i>	<i>t.incident_cells(Cell_handle c, int i, int j)</i>	As above for edge (i,j) of <i>c</i> .
<i>Cell_circulator</i>	<i>t.incident_cells(Edge e, Cell_handle start)</i>	Starts at cell <i>start</i> . Precondition: <i>t.dimension() = 3</i> and <i>start</i> is incident to <i>e</i> .
<i>Cell_circulator</i>	<i>t.incident_cells(Cell_handle c, int i, int j, Cell_handle start)</i>	As above for edge (i,j) of <i>c</i> .

The following circulators on facets are defined only in dimension 3, though facets are defined also in dimension 2: there are only two facets sharing an edge in dimension 2.

<i>Facet_circulator</i>	<i>t.incident_facets(Edge e)</i>	Starts at an arbitrary facet incident to <i>e</i> . Precondition: <i>t.dimension() = 3</i>
<i>Facet_circulator</i>	<i>t.incident_facets(Cell_handle c, int i, int j)</i>	As above for edge (i,j) of <i>c</i> .
<i>Facet_circulator</i>	<i>t.incident_facets(Edge e, Facet start)</i>	Starts at facet <i>start</i> . Precondition: <i>start</i> is incident to <i>e</i> .
<i>Facet_circulator</i>	<i>t.incident_facets(Edge e, Cell_handle start, int f)</i>	Starts at facet of index <i>f</i> in <i>start</i> .
<i>Facet_circulator</i>	<i>t.incident_facets(Cell_handle c, int i, int j, Facet start)</i>	As above for edge (i,j) of <i>c</i> .
<i>Facet_circulator</i>	<i>t.incident_facets(Cell_handle c, int i, int j, Cell_handle start, int f)</i>	As above for edge (i,j) of <i>c</i> and facet (start,f).

Traversal of the incident cells, facets and edges, and the adjacent vertices of a given vertex

```
template <class OutputIterator>
OutputIterator t.incident_cells( Vertex_handle v, OutputIterator cells)
```

Copies the *Cell_handles* of all cells incident to *v* to the output iterator *cells*. Returns the resulting output iterator.
Precondition: *t.dimension() = 3*, *v* \neq *Vertex_handle()*, *t.is_vertex(v)*.

```
template <class OutputIterator>
```

OutputIterator *t*.finite_incident_cells(*Vertex_handle* *v*, *OutputIterator* *cells*)

Copies the *Cell_handles* of all finite cells incident to *v* to the output iterator *cells*. Returns the resulting output iterator.

Precondition: t.dimension() = 3, v ≠ Vertex_handle(), t.is_vertex(v).

template <class OutputIterator>

OutputIterator *t*.incident_facets(*Vertex_handle* *v*, *OutputIterator* *facets*)

Copies all *Facets* incident to *v* to the output iterator *facets*. Returns the resulting output iterator.

Precondition: t.dimension() > 1, v ≠ Vertex_handle(), t.is_vertex(v).

template <class OutputIterator>

OutputIterator *t*.finite_incident_facets(*Vertex_handle* *v*, *OutputIterator* *facets*)

Copies all finite *Facets* incident to *v* to the output iterator *facets*. Returns the resulting output iterator.

Precondition: t.dimension() > 1, v ≠ Vertex_handle(), t.is_vertex(v).

template <class OutputIterator>

OutputIterator *t*.incident_edges(*Vertex_handle* *v*, *OutputIterator* *edges*)

Copies all *Edges* incident to *v* to the output iterator *edges*. Returns the resulting output iterator.

Precondition: t.dimension() > 0, v ≠ Vertex_handle(), t.is_vertex(v).

template <class OutputIterator>

OutputIterator *t*.finite_incident_edges(*Vertex_handle* *v*, *OutputIterator* *edges*)

Copies all finite *Edges* incident to *v* to the output iterator *edges*. Returns the resulting output iterator.

Precondition: t.dimension() > 0, v ≠ Vertex_handle(), t.is_vertex(v).

template <class OutputIterator>

OutputIterator *t*.adjacent_vertices(*Vertex_handle* *v*, *OutputIterator* *vertices*)

Copies the *Vertex_handles* of all vertices adjacent to *v* to the output iterator *vertices*. If *t.dimension() < 0*, then do nothing. Returns the resulting output iterator.

Precondition: v ≠ Vertex_handle(), t.is_vertex(v).

template <class OutputIterator>

OutputIterator *t*.finite_adjacent_vertices(*Vertex_handle* *v*, *OutputIterator* *vertices*)

Copies the *Vertex_handles* of all finite vertices adjacent to *v* to the output iterator *vertices*. If *t.dimension() < 0*, then do nothing. Returns the resulting output iterator.

Precondition: v ≠ Vertex_handle(), t.is_vertex(v).

size_type *t.degree(Vertex_handle v)*

Returns the degree of a vertex, that is, the number of incident vertices.
The infinite vertex is counted.
Precondition: $v \neq \text{Vertex_handle}()$, $t.\text{is_vertex}(v)$.

Traversal between adjacent cells

int *t.mirror_index(Cell_handle c, int i)*

Returns the index of c in its i^{th} neighbor.
Precondition: $i \in \{0, 1, 2, 3\}$.

Vertex_handle *t.mirror_vertex(Cell_handle c, int i)*

Returns the vertex of the i^{th} neighbor of c that is opposite to c .
Precondition: $i \in \{0, 1, 2, 3\}$.

Facet *t.mirror_facet(Facet f)*

Returns the same facet viewed from the other adjacent cell.

└────────── debugging support ─────────┘

Checking

The responsibility of keeping a valid triangulation belongs to the user when using advanced operations allowing a direct manipulation of cells and vertices. We provide the user with the following methods to help debugging.

bool *t.is_valid(bool verbose = false)*

Checks the combinatorial validity of the triangulation. Checks also the validity of its geometric embedding (see Section 37.1).
When *verbose* is set to true, messages describing the first invalidity encountered are printed.

bool *t.is_valid(Cell_handle c, bool verbose = false)*

Checks the combinatorial validity of the cell by calling the *is_valid* method of the *TriangulationDataStructure_3* cell class. Also checks the geometric validity of c , if c is finite. (See Section 2442.)
When *verbose* is set to *true*, messages are printed to give a precise indication of the kind of invalidity encountered.

└────────── debugging support ─────────┘

I/O

CGAL provides an interface to Geomview for a 3D-triangulation, see Chapter 78 on *Geomview_stream*. `#include <CGAL/IO/Triangulation-geomview_ostream_3.h>`

<i>istream</i> &	<i>istream</i> & <i>is</i> >> <i>Triangulation_3</i> & <i>t</i>	Reads the underlying combinatorial triangulation from <i>is</i> by calling the corresponding input operator of the triangulation data structure class (note that the infinite vertex is numbered 0), and the non-combinatorial information by calling the corresponding input operators of the vertex and the cell classes (such as point coordinates), which are provided by overloading the stream operators of the vertex and cell types. Assigns the resulting triangulation to <i>t</i> .
<i>ostream</i> &	<i>ostream</i> & <i>os</i> << <i>Triangulation_3</i> <i>t</i>	Writes the triangulation <i>t</i> into <i>os</i> .

The information in the *iostream* is: the dimension, the number of finite vertices, the non-combinatorial information about vertices (point, etc; note that the infinite vertex is numbered 0), the number of cells, the indices of the vertices of each cell, plus the non-combinatorial information about each cell, then the indices of the neighbors of each cell, where the index corresponds to the preceding list of cells. When dimension < 3, the same information is stored for faces of maximal dimension instead of cells.

CGAL::Delaunay_triangulation_3<DelaunayTriangulationTraits_3, TriangulationDataStructure_3, LocationPolicy>

Definition

The class *Delaunay_triangulation_3* represents a three-dimensional Delaunay triangulation.

```
#include <CGAL/Delaunay_triangulation_3.h>
```

Parameters

The first template argument must be a model of the *DelaunayTriangulationTraits_3* concept.

The second template argument must be a model of the *TriangulationDataStructure_3* concept. It has the default value *Triangulation_data_structure_3<Triangulation_vertex_base_3<DelaunayTriangulationTraits_3>, Triangulation_cell_base_3<DelaunayTriangulationTraits_3>>*.

The third template argument is a tag which must be a *Location_policy<Tag>*: either *Fast_location* or *Compact_location*. *Fast_location* offers faster ($O(\log n)$ time) point location, which can be beneficial when performing point locations or random point insertions (with no good location hint) in large data sets. It is currently implemented using an additional triangulation hierarchy data structure [Dev02]. The default is *Compact_location*, which saves memory (3-5%) by avoiding the need for this separate data structure, and point location is then performed roughly in $O(n^{1/3})$ time. Note that this argument can also come in second position, which can be useful when the default value for the *TriangulationDataStructure_3* parameter is satisfactory (this is using so-called deduced parameters). Note that this argument replaces the functionality provided before CGAL 3.6 by *Triangulation_hierarchy_3*. An example of use can be found in the user manual 37.5.4.

Inherits From

Triangulation_3<DelaunayTriangulationTraits_3, TriangulationDataStructure_3>

Types

```
typedef LocationPolicy                                     Location_policy;
```

In addition to those inherited, the following types are defined, for use by the construction of the Voronoi diagram:

```
typedef DelaunayTriangulationTraits_3::Line_3             Line;
typedef DelaunayTriangulationTraits_3::Ray_3              Ray;
typedef DelaunayTriangulationTraits_3::Plane_3           Plane;
typedef DelaunayTriangulationTraits_3::Object_3          Object;
```

Creation

```
Delaunay_triangulation_3<DelaunayTriangulationTraits_3, TriangulationDataStructure_3, LocationPolicy>
dt( DelaunayTriangulationTraits_3 traits = DelaunayTriangulationTraits_3())
```

Creates an empty Delaunay triangulation, possibly specifying a traits class *traits*.

```
Delaunay_triangulation_3<DelaunayTriangulationTraits_3,TriangulationDataStructure_3,LocationPolicy>
dt( Delaunay_triangulation_3 dt1)
```

Copy constructor.

```
template < class InputIterator >
Delaunay_triangulation_3<DelaunayTriangulationTraits_3,TriangulationDataStructure_3,LocationPolicy>
dt( InputIterator first,

putIterator last,

3 traits = DelaunayTriangulationTraits_3())
```

In-

DelaunayTriangulation_3

Equivalent to constructing an empty triangulation with the optional traits class argument and calling *insert(first,last)*.

Operations

Insertion

The following methods overload the corresponding methods of triangulations to ensure the empty sphere property of Delaunay triangulations.

In the degenerate case when there are co-spherical points, the Delaunay triangulation is known not to be uniquely defined. In this case, CGAL chooses a particular Delaunay triangulation using a symbolic perturbation scheme [DT03].

```
Vertex_handle dt.insert( Point p, Cell_handle start = Cell_handle() )
```

Inserts point *p* in the triangulation and returns the corresponding vertex. Similar to the insertion in a triangulation, but ensures in addition the empty sphere property of all the created faces. The optional argument *start* is used as a starting place for the search.

```
Vertex_handle dt.insert( Point p, Vertex_handle hint )
```

Same as above but uses *hint* as a starting place for the search.

```
Vertex_handle dt.insert( Point p, Locate_type lt, Cell_handle loc, int li, int lj )
```

Inserts point *p* in the triangulation and returns the corresponding vertex. Similar to the above *insert()* function, but takes as additional parameter the return values of a previous location query. See description of *Triangulation_3::locate()*.

The following method allows one to insert several points. It returns the number of inserted points.

```
template < class InputIterator >
```

std::ptrdiff_t *dt.insert(InputIterator first, InputIterator last)*

Inserts the points in the iterator range $[first, last)$. Returns the number of inserted points. Note that this function is not guaranteed to insert the points following the order of *InputIterator*, as *spatial_sort* is used to improve efficiency.

Precondition: The *value_type* of *first* and *last* is *Point*.

Displacement

Vertex_handle *dt.move_if_no_collision(Vertex_handle v, Point p)*

if there is not already another vertex placed on p , the triangulation is modified such that the new position of vertex v is p , and v is returned. Otherwise, the triangulation is not modified and the vertex at point p is returned.

Precondition: Vertex v must be finite.

Vertex_handle *dt.move(Vertex_handle v, Point p)*

same as above if there is no collision. Otherwise, v is deleted and the vertex placed on p is returned.

Precondition: Vertex v must be finite.

Removal

When a vertex v is removed from a triangulation, all the cells incident to v must be removed, and the polyhedral region consisting of all the tetrahedra that are incident to v must be re-triangulated. So, the problem reduces to triangulating a polyhedral region, while preserving its boundary, or to compute a *constrained* triangulation. This is known to be sometimes impossible: the Schönhardt polyhedron cannot be triangulated [She98].

However, when dealing with Delaunay triangulations, the case of such polyhedra that cannot be re-triangulated cannot happen, so CGAL proposes a vertex removal.

void *dt.remove(Vertex_handle v)*

Removes the vertex v from the triangulation.

Precondition: v is a finite vertex of the triangulation.

template < typename InputIterator >

int *dt.remove(InputIterator first, InputIterator beyond)*

Removes the vertices specified by the iterator range $[first, beyond)$ of value type *Vertex_handle*. *remove()* is called over each element of the range. The number of vertices removed is returned.

Precondition: All vertices of the range are finite vertices of the triangulation.

Queries

Bounded_side *dt.side_of_sphere(Cell_handle c, Point p)*

Returns a value indicating on which side of the circumscribed sphere of *c* the point *p* lies. More precisely, it returns:

- *ON_BOUNDED_SIDE* if *p* is inside the sphere. For an infinite cell this means that *p* lies strictly either in the half space limited by its finite facet and not containing any other point of the triangulation, or in the interior of the disk circumscribing the *finite* facet.
- *ON_BOUNDARY* if *p* on the boundary of the sphere. For an infinite cell this means that *p* lies on the circle circumscribing the *finite* facet.
- *ON_UNBOUNDED_SIDE* if *p* lies outside the sphere. For an infinite cell this means that *p* does not satisfy either of the two previous conditions.

Precondition: dt.dimension() = 3.

Bounded_side *dt.side_of_circle(Facet f, Point p)*

Returns a value indicating on which side of the circumscribed circle of *f* the point *p* lies. More precisely, it returns:

- in dimension 3:
 - For a finite facet, *ON_BOUNDARY* if *p* lies on the circle, *ON_UNBOUNDED_SIDE* when it lies in the exterior of the disk, *ON_BOUNDED_SIDE* when it lies in its interior.
 - For an infinite facet, it considers the plane defined by the finite facet of the same cell, and does the same as in dimension 2 in this plane.
- in dimension 2:
 - For a finite facet, *ON_BOUNDARY* if *p* lies on the circle, *ON_UNBOUNDED_SIDE* when it lies in the exterior of the disk, *ON_BOUNDED_SIDE* when it lies in its interior.
 - For an infinite facet, *ON_BOUNDARY* if the point lies on the finite edge of *f* (endpoints included), *ON_BOUNDED_SIDE* for a point in the open half plane defined by *f* and not containing any other point of the triangulation, *ON_UNBOUNDED_SIDE* elsewhere.

Precondition: dt.dimension() ≥ 2 and in dimension 3, p is coplanar with f.

Bounded_side *dt.side_of_circle(Cell_handle c, int i, Point p)*

Same as the previous method for facet *i* of cell *c*.

Vertex_handle *dt.nearest_vertex(Point p, Cell_handle c = Cell_handle())*

Returns any nearest vertex to the point *p*, or the default constructed handle if the triangulation is empty. The optional argument *c* is a hint specifying where to start the search.

Precondition: c is a cell of dt.

Vertex_handle *dt.nearest_vertex_in_cell(Point p, Cell_handle c)*

Returns the vertex of the cell *c* that is nearest to *p*.

A point p is said to be in conflict with a cell c in dimension 3 (resp. a facet f in dimension 2) iff $dt.side_of_sphere(c, p)$ (resp. $dt.side_of_circle(f, p)$) returns *ON_BOUNDED_SIDE*. The set of cells (resp. facets in dimension 2) which are in conflict with p is connected, and it forms a hole.

```
template <class OutputIteratorBoundaryFacets, class OutputIteratorCells>
std::pair<OutputIteratorBoundaryFacets, OutputIteratorCells>
```

```
dt.find_conflicts( Point p,
                  Cell_handle c,
                  OutputIteratorBoundaryFacets bfit,
                  OutputIteratorCells cit)
```

Computes the conflict hole induced by p . The starting cell (resp. facet) c must be in conflict. Then this function returns respectively in the output iterators:

- *cit*: the cells (resp. facets) in conflict.
- *bfit*: the facets (resp. edges) on the boundary, that is, the facets (resp. edges) (t, i) where the cell (resp. facet) t is in conflict, but $t \rightarrow neighbor(i)$ is not.

This function can be used in conjunction with *insert_in_hole()* in order to decide the insertion of a point after seeing which elements of the triangulation are affected. Returns the pair composed of the resulting output iterators.

Precondition: $dt.dimension() \geq 2$, and c is in conflict with p .

```
template <class OutputIteratorBoundaryFacets, class OutputIteratorCells, class OutputIteratorInternalFacets>
```

```
Triple<OutputIteratorBoundaryFacets, OutputIteratorCells, OutputIteratorInternalFacets>
```

```
dt.find_conflicts( Point p,
                  Cell_handle c,
                  OutputIteratorBoundaryFacets bfit,
                  OutputIteratorCells cit,
                  OutputIteratorInternalFacets ifit)
```

Same as the other *find_conflicts()* function, except that it also computes the internal facets, i.e. the facets common to two cells which are in conflict with p . Then this function returns respectively in the output iterators:

- *cit*: the cells (resp. facets) in conflict.
- *bfit*: the facets (resp. edges) on the boundary, that is, the facets (resp. edges) (t, i) where the cell (resp. facet) t is in conflict, but $t \rightarrow neighbor(i)$ is not.
- *ifit*: the facets (resp. edges) inside the hole, that is, delimiting two cells (resp. facets) in conflict.

Returns the *Triple* composed of the resulting output iterators.

Precondition: $dt.dimension() \geq 2$, and c is in conflict with p .

```
template <class OutputIterator>
OutputIterator
```

```
dt.vertices_in_conflict( Point p, Cell_handle c, OutputIterator res)
```

Similar to *find_conflicts()*, but reports the vertices which are on the boundary of the conflict hole of p , in the output iterator *res*. Returns the resulting output iterator.

Precondition: $dt.dimension() \geq 2$, and c is in conflict with p .

A face (cell, facet or edge) is said to be a Gabriel face iff its smallest circumscribing sphere do not enclose any vertex of the triangulation. Any Gabriel face belongs to the Delaunay triangulation, but the reciprocal is not true. The following member functions test the Gabriel property of Delaunay faces.

```
bool          dt.is_Gabriel( Cell_handle c, int i)
bool          dt.is_Gabriel( Cell_handle c, int i, int j)
bool          dt.is_Gabriel( Facet f)
bool          dt.is_Gabriel( Edge e)
```

Voronoi diagram

CGAL offers several functionalities to display the Voronoi diagram of a set of points in 3D.

Note that the user should use a kernel with exact constructions in order to guarantee the computation of the Voronoi diagram (as opposed to computing the triangulation only, which requires only exact predicates).

```
Point          dt.dual( Cell_handle c)
```

Returns the circumcenter of the four vertices of c .
Precondition: $dt.dimension() = 3$ and c is not infinite.

```
Object          dt.dual( Facet f)
```

Returns the dual of facet f , which is
in dimension 3: either a segment, if the two cells incident to f are finite, or a ray, if one of them is infinite;
in dimension 2: a point.
Precondition: $dt.dimension() \geq 2$ and f is not infinite.

```
Object          dt.dual( Cell_handle c, int i)
```

same as the previous method for facet (c,i) .

```
Line           dt.dual_support( Cell_handle c, int i)
```

returns the line supporting the dual of the facet.
Precondition: $dt.dimension() \geq 2$ and f is not infinite.

```
template <class Stream>
Stream&         dt.draw_dual( Stream & os)
```

Sends the set of duals to all the facets of dt into os .

— debugging support —

Checking

bool *dt.is_valid(bool verbose = false)*

Checks the combinatorial validity of the triangulation and the validity of its geometric embedding (see Section 37.1). Also checks that all the circumscribing spheres (resp. circles in dimension 2) of cells (resp. facets in dimension 2) are empty.

When *verbose* is set to true, messages describing the first invalidity encountered are printed.

bool *dt.is_valid(Cell_handle c, bool verbose = false)*

Checks the combinatorial and geometric validity of the cell (see Section 37.1). Also checks that the circumscribing sphere (resp. circle in dimension 2) of cells (resp. facet in dimension 2) is empty.

When *verbose* is set to true, messages are printed to give a precise indication of the kind of invalidity encountered.

These methods are mainly a debugging help for the users of advanced features.

CGAL::Regular_triangulation_3

CGAL::Triangulation_hierarchy_3<Tr>

— deprecated —

Note : this class is deprecated since CGAL 3.6. Its functionality has been replaced by the use of the *Fast_location* tag as the *LocationPolicy* template parameter in *Delaunay_triangulation_3*.

Definition

The class *Triangulation_hierarchy_3* implements a triangulation augmented with a data structure which allows fast point location queries. As proved in [Dev02], this structure has an optimal behavior when it is built for Delaunay triangulations. It can however be used for other triangulations.

```
#include <CGAL/Triangulation_hierarchy_3.h>
```

Parameters

It is templated by a parameter which must be instantiated by one of the CGAL triangulation classes. *In the current implementation, only Delaunay_triangulation_3 is supported for Tr.*

Tr::Vertex has to be a model of the concept *TriangulationHierarchyVertexBase_3*.

Tr::Geom_traits has to be a model of the concept *DelaunayTriangulationTraits_3*.

Inherits From

Tr

Triangulation_hierarchy_3<Tr> offers exactly the same functionalities as *Tr*. Most of them (point location, insertion, removal...) are overloaded to improve their efficiency by using the hierarchic structure.

Note that, since the algorithms that are provided are randomized, the running time of constructing a triangulation with a hierarchy may be improved when shuffling the data points.

However, the I/O operations are not overloaded. So, writing a hierarchy into a file will lose the hierarchic structure and reading it from the file will result in an ordinary triangulation whose efficiency will be the same as *Tr*.

Implementation

The data structure is a hierarchy of triangulations. The triangulation at the lowest level is the original triangulation where operations and point location are to be performed. Then at each succeeding level, the data structure stores a triangulation of a small random sample of the vertices of the triangulation at the preceding level. Point location is done through a top-down nearest neighbor query. The nearest neighbor query is first performed naively in the top level triangulation. Then, at each following level, the nearest neighbor at that level is found through a linear walk performed from the nearest neighbor found at the preceding level. Because the number of vertices in each triangulation is only a small fraction of the number of vertices of the preceding triangulation the data structure remains small and achieves fast point location queries on real data.

└────────── deprecated ─────────┘

CGAL::Regular_triangulation_3<RegularTriangulationTraits_3, TriangulationDataStructure_3>

Definition

Let $S^{(w)}$ be a set of weighted points in \mathbb{R}^3 . Let $p^{(w)} = (p, w_p)$, $p \in \mathbb{R}^3$, $w_p \in \mathbb{R}$ and $z^{(w)} = (z, w_z)$, $z \in \mathbb{R}^3$, $w_z \in \mathbb{R}$ be two weighted points. A weighted point $p^{(w)} = (p, w_p)$ can also be seen as a sphere of center p and radius $\sqrt{w_p}$. The *power product* (or *power distance*) between $p^{(w)}$ and $z^{(w)}$ is defined as

$$\Pi(p^{(w)}, z^{(w)}) = \|p - z\|^2 - w_p - w_z$$

where $\|p - z\|$ is the Euclidean distance between p and z . $p^{(w)}$ and $z^{(w)}$ are said to be *orthogonal* if $\Pi(p^{(w)} - z^{(w)}) = 0$ (see Figure 37.2).

Four weighted points have a unique common orthogonal weighted point called the *power sphere*. A sphere $z^{(w)}$ is said to be *regular* if $\forall p^{(w)} \in S^{(w)}, \Pi(p^{(w)} - z^{(w)}) \geq 0$.

A triangulation of $S^{(w)}$ is *regular* if the power spheres of all simplices are regular.

```
#include <CGAL/Regular_triangulation_3.h>
```

Parameters

The first template argument must be a model of the *RegularTriangulationTraits_3* concept.

The second template argument must be a model of the *TriangulationDataStructure_3* concept. It has the default value *Triangulation_data_structure_3<Triangulation_vertex_base_3<RegularTriangulationTraits_3>, Regular_triangulation_cell_base_3<RegularTriangulationTraits_3>>*.

Inherits From

Triangulation_3<RegularTriangulationTraits_3, TriangulationDataStructure_3>

Types

```
typedef RegularTriangulationTraits_3::Bare_point      Bare_point;      The type for points  $p$  of
                                                    weighted points  $p^{(w)} = (p, w_p)$ 

typedef RegularTriangulationTraits_3::Weighted_point_3  Weighted_point;
```

Creation

```
Regular_triangulation_3<RegularTriangulationTraits_3, TriangulationDataStructure_3>      rt(
RegularTriangulationTraits_3 traits = RegularTriangulationTraits_3())
```

Creates an empty regular triangulation, possibly specifying a traits class *traits*.

Regular_triangulation_3<*RegularTriangulationTraits_3*,*TriangulationDataStructure_3*> *rt*(*Regular_triangulation_3* *rt1*)

Copy constructor.

```
template < class InputIterator >
Regular_triangulation_3<RegularTriangulationTraits_3, TriangulationDataStructure_3> rt( InputIterator first,
InputIterator last,
RegularTriangulationTraits_
3 traits = RegularTriangulationTraits_3())
```

Equivalent to constructing an empty triangulation with the optional traits class argument and calling *insert(first,last)*.

Operations

Insertion

The following methods, which already exist in triangulations, are overloaded to ensure the property that all power spheres are regular.

Vertex_handle *rt.insert*(*Weighted_point* *p*, *Cell_handle* *start* = *Cell_handle*())

Inserts weighted point *p* in the triangulation. The optional argument *start* is used as a starting place for the search.

If this insertion creates a vertex, this vertex is returned.

If *p* coincides with an existing vertex and has a greater weight, then the existing weighted point becomes hidden (see *RegularTriangulationCellBase_3*) and *p* replaces it as vertex of the triangulation.

If *p* coincides with an already existing vertex (both point and weights being equal), then this vertex is returned and the triangulation remains unchanged.

Otherwise if *p* does not appear as a vertex of the triangulation, then it is stored as a hidden point and this method returns the default constructed handle.

Vertex_handle *rt.insert*(*Weighted_point* *p*, *Vertex_handle* *hint*)

Same as above but uses *hint* as a starting place for the search.

Vertex_handle *rt.insert*(*Weighted_point* *p*, *Locate_type* *lt*, *Cell_handle* *loc*, *int* *li*, *int* *lj*)

Inserts weighted point *p* in the triangulation and returns the corresponding vertex. Similar to the above *insert()* function, but takes as additional parameter the return values of a previous location query. See description of *Triangulation_3::locate()*.

The following method allows one to insert several points.

```
template < class InputIterator >
```

std::ptrdiff_t *rt.insert(InputIterator first, InputIterator last)*

Inserts the weighted points in the range $[first, last)$. Note that this function is not guaranteed to insert the points following the order of *InputIterator*. It returns the difference of the number of vertices between after and before the insertions (it may be negative due to hidden points).

Precondition: The *value_type* of *first* and *last* is *Point*.

Removal

void *rt.remove(Vertex_handle v)*

Removes the vertex v from the triangulation.

Queries

Let us remark that

$$\Pi(p^{(w)} - z^{(w)}) > 0$$

is equivalent to

p lies outside the sphere with center z and radius $\sqrt{w_p^2 + w_z^2}$.

This remark helps provide an intuition about the following predicates.

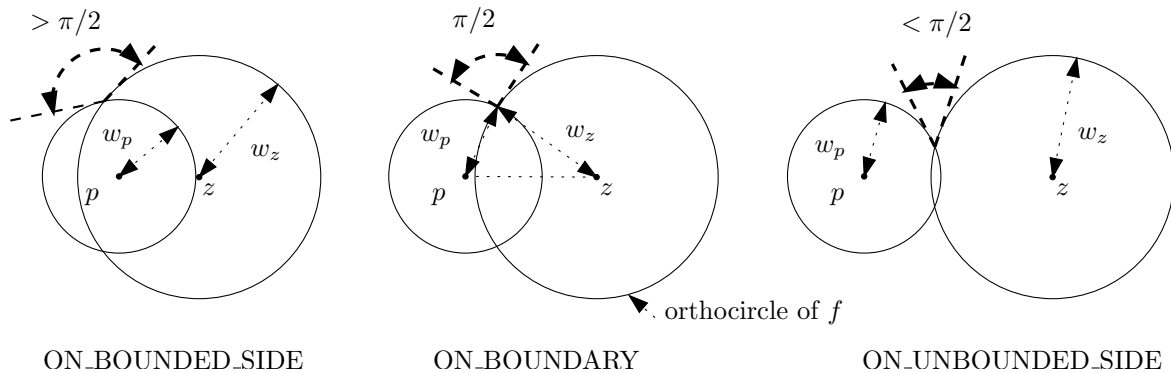

Figure 37.13: side_of_power_circle.

Bounded_side *rt.side_of_power_sphere(Cell_handle c, Weighted_point p)*

Returns the position of the weighted point p with respect to the power sphere of c . More precisely, it returns:

- *ON_BOUNDED_SIDE* if $\Pi(p^{(w)} - z(c)^{(w)}) < 0$ where $z(c)^{(w)}$ is the power sphere of c . For an infinite cell this means either that p lies strictly in the half space limited by its finite facet and not containing any other point of the triangulation, or that the angle between p and the power circle of the *finite* facet of c is greater than $\pi/2$.

- *ON_BOUNDARY* if p is orthogonal to the power sphere of c i.e. $\Pi(p^{(w)} - z(c)^{(w)}) = 0$. For an infinite cell this means that p is orthogonal to the power circle of its *finite* facet.

- *ON_UNBOUNDED_SIDE* if $\Pi(p^{(w)} - z(c)^{(w)}) > 0$ i.e. the angle between the weighted point p and the power sphere of c is less than $\pi/2$ or if these two spheres do not intersect. For an infinite cell this means that p does not satisfy either of the two previous conditions.

Precondition: rt.dimension() = 3.

Bounded_side *rt.side_of_power_circle(Facet f, Weighted_point p)*

Returns the position of the point p with respect to the power circle of f . More precisely, it returns:

- in dimension 3:

- For a finite facet,

ON_BOUNDARY if p is orthogonal to the power circle in the plane of the facet,

ON_UNBOUNDED_SIDE when their angle is less than $\pi/2$,

ON_BOUNDED_SIDE when it is greater than $\pi/2$ (see Figure 37.13).

- For an infinite facet, it considers the plane defined by the finite facet of the cell *f.first*, and does the same as in dimension 2 in this plane.

- in dimension 2:

- For a finite facet,

ON_BOUNDARY if p is orthogonal to the circle,

ON_UNBOUNDED_SIDE when the angle between p and the power circle of f is less than $\pi/2$, *ON_BOUNDED_SIDE* when it is greater than $\pi/2$.

- For an infinite facet,

ON_BOUNDED_SIDE for a point in the open half plane defined by f and not containing any other point of the triangulation,

ON_UNBOUNDED_SIDE in the other open half plane.

If the point p is collinear with the finite edge e of f , it returns:

ON_BOUNDED_SIDE if $\Pi(p^{(w)} - z(e)^{(w)}) < 0$, where $z(e)^{(w)}$ is the power segment of e in the line supporting e ,

ON_BOUNDARY if $\Pi(p^{(w)} - z(e)^{(w)}) = 0$,

ON_UNBOUNDED_SIDE if $\Pi(p^{(w)} - z(e)^{(w)}) > 0$.

Precondition: rt.dimension() ≥ 2.

Bounded_side *rt.side_of_power_circle(Cell_handle c, int i, Weighted_point p)*

Same as the previous method for facet i of cell c .

Bounded_side *rt.side_of_power_segment(Cell_handle c, Weighted_point p)*

In dimension 1, returns

ON_BOUNDED_SIDE if $\Pi(p^{(w)} - z(c)^{(w)}) < 0$, where $z(c)^{(w)}$ is the power segment of the edge represented by *c*,

ON_BOUNDARY if $\Pi(p^{(w)} - z(c)^{(w)}) = 0$,

ON_UNBOUNDED_SIDE if $\Pi(p^{(w)} - z(c)^{(w)}) > 0$.

Precondition: *rt.dimension()* = 1.

Vertex_handle

rt.nearest_power_vertex(Point p, Cell_handle c = Cell_handle())

Returns the vertex of the triangulation which is nearest to *p* with respect to the power distance. This means that the power of the query point *p* with respect to the weighted point in the returned vertex is smaller than the power of *p* with respect to the weighted point in any other vertex. Ties are broken arbitrarily. The default constructed handle is returned if the triangulation is empty. The optional argument *c* is a hint specifying where to start the search.

Precondition: *c* is a cell of *rt*.

Vertex_handle

rt.nearest_power_vertex_in_cell(Point p, Cell_handle c)

Returns the vertex of the cell *c* that is nearest to *p* with respect to the power distance.

A weighted point *p* is said to be in conflict with a cell *c* in dimension 3 (resp. with a facet *f* in dimension 2) if it has a negative power distance to the power sphere of *c* (resp. to the power circle of *f*). The set of cells (resp. facets in dimension 2) which are in conflict with *p* is connected.

template <class OutputIteratorBoundaryFacets, class OutputIteratorCells, class OutputIteratorInternalFacets>

Triple<OutputIteratorBoundaryFacets, OutputIteratorCells, OutputIteratorInternalFacets>

rt.find_conflicts(const Weighted_point p,
 Cell_handle c,
 OutputIteratorBoundaryFacets bfit,
 OutputIteratorCells cit,
 OutputIteratorInternalFacets ifit)

Compute the conflicts with *p*. The starting cell (resp. facet) *c* must be in conflict with *p*. Then this function returns respectively in the output iterators:

- *cit*: the cells (resp. facets) in conflict with *p*.
- *bfit*: the facets (resp. edges) on the boundary of the conflict zone, that is, the facets (resp. edges) (*t*, *i*) where the cell (resp. facet) *t* is in conflict, but *t*→*neighbor*(*i*) is not.
- *ifit*: the facets (resp. edges) inside the conflict zone, that facets incident to two cells (resp. facets) in conflict.

Returns the *Triple* composed of the resulting output iterators.

Precondition: *rt.dimension()* ≥ 2, and *c* is in conflict with *p*.

```
template <class OutputIterator>
OutputIterator
```

```
rt.vertices_in_conflict( Point p, Cell_handle c, OutputIterator res)
```

Similar to *find_conflicts()*, but reports the vertices which are on the boundary of the conflict hole of *p*, in the output iterator *res*. Returns the resulting output iterator.

Precondition: *rt.dimension()* ≥ 2 , and *c* is a cell containing *p*.

In the weighted setting, a face (cell, facet, edge or vertex) is said to be a Gabriel face iff the smallest sphere orthogonal to the weighted points associated to its vertices, has a positive power product with the weighted point of any other vertex of the triangulation. Any weighted Gabriel face belongs to the regular triangulation, but the reciprocal is not true. The following member functions test the Gabriel property of the faces of the regular triangulation.

```
bool          rt.is_Gabriel( Cell_handle c, int i)
bool          rt.is_Gabriel( Cell_handle c, int i, int j)
bool          rt.is_Gabriel( Facet f)
bool          rt.is_Gabriel( Edge e)
bool          rt.is_Gabriel( Vertex_handle v)
```

Power diagram

CGAL offers several functionalities to display the Power diagram of a set of points in 3D.

Note that the user should use a kernel with exact constructions in order to guarantee the computation of the Voronoi diagram (as opposed to computing the triangulation only, which requires only exact predicates).

```
Point          rt.dual( Cell_handle c)
```

Returns the weighted circumcenter of the four vertices of *c*.

Precondition: *rt.dimension()* = 3 and *c* is not infinite.

```
Object          rt.dual( Facet f)
```

Returns the dual of facet *f*, which is
in dimension 3: either a segment, if the two cells incident to *f* are finite,
or a ray, if one of them is infinite;
in dimension 2: a point.

Precondition: *rt.dimension()* ≥ 2 and *f* is not infinite.

```
Object          rt.dual( Cell_handle c, int i)
```

same as the previous method for facet *(c,i)*.

```
template <class Stream>
Stream&          rt.draw_dual( Stream & os)
```

Sends the set of duals to all the facets of *rt* into *os*.

— debugging support —

Checking

bool *rt.is_valid(bool verbose = false)*

Checks the combinatorial validity of the triangulation and the validity of its geometric embedding (see Section [37.1](#)). Also checks that all the power spheres (resp. power circles in dimension 2, power segments in dimension 1) of cells (resp. facets in dimension 2, edges in dimension 1) are regular. When *verbose* is set to true, messages describing the first invalidity encountered are printed.

This method is mainly a debugging help for the users of advanced features.

└────────── *debugging support* ─────────┘

TriangulationTraits_3

Definition

The concept `TriangulationTraits_3` is the first template parameter of the class `Triangulation_3`. It defines the geometric objects (points, segments, triangles and tetrahedra) forming the triangulation together with a few geometric predicates and constructions on these objects : lexicographical comparison, orientation in case of coplanar points and orientation in space.

Types

`TriangulationTraits_3::Point_3` The point type. It must be *DefaultConstructible*, *CopyConstructible* and *Assignable*.

`TriangulationTraits_3::Segment_3` The segment type.

`TriangulationTraits_3::Tetrahedron_3` The tetrahedron type.

`TriangulationTraits_3::Triangle_3` The triangle type.

`TriangulationTraits_3::Construct_segment_3`

A constructor object that must provide the function operator
`Segment_3 operator()(Point_3 p, Point_3 q)`,
which constructs a segment from two points.

`TriangulationTraits_3::Construct_triangle_3`

A constructor object that must provide the function operator
`Triangle_3 operator()(Point_3 p, Point_3 q, Point_3 r)`,
which constructs a triangle from three points.

`TriangulationTraits_3::Construct_tetrahedron_3`

A constructor object that must provide the function operator
`Tetrahedron_3 operator()(Point_3 p, Point_3 q, Point_3 r, Point_3 s)`,
which constructs a tetrahedron from four points.

`TriangulationTraits_3::Compare_xyz_3`

A predicate object that must provide the function operator
`Comparison_result operator()(Point p, Point q)`,
which returns *EQUAL* if the two points are equal. Otherwise it must return a consistent order for any two points chosen in a same line.

`TriangulationTraits_3::Coplanar_orientation_3`

A predicate object that must provide the function operator
`Orientation operator()(Point p, Point q, Point r)`,
which returns *COLLINEAR* if the points are collinear. Otherwise it must return a consistent orientation for any three points chosen in a same plane.

TriangulationTraits_3:: Orientation_3

A predicate object that must provide the function operator
Orientation operator()(Point p, Point q, Point r, Point s),
which returns POSITIVE, if *s* lies on the positive side of the oriented plane *h* defined
by *p*, *q*, and *r*, returns NEGATIVE if *s* lies on the negative side of *h*, and returns
COPLANAR if *s* lies on *h*.

Creation

<i>TriangulationTraits_3 traits;</i>	Default constructor.
<i>TriangulationTraits_3 traits(Triangulation_traits_3 tr);</i>	Copy constructor.

Operations

The following functions give access to the predicate and construction objects:

<i>Construct_tetrahedron_3</i>	<i>traits.construct_tetrahedron_3_object()</i>
<i>Construct_triangle_3</i>	<i>traits.construct_triangle_3_object()</i>
<i>Construct_segment_3</i>	<i>traits.construct_segment_3_object()</i>
<i>Compare_xyz_3</i>	<i>traits.compare_xyz_3_object()</i>
<i>Coplanar_orientation_3</i>	<i>traits.coplanar_orientation_3_object()</i>
<i>Orientation_3</i>	<i>traits.orientation_3_object()</i>

CGAL::Simple_cartesian
CGAL::Homogeneous
CGAL::Simple_homogeneous

DelaunayTriangulationTraits_3

Definition

The concept `DelaunayTriangulationTraits_3` is the first template parameter of the class `Delaunay_triangulation_3`. It defines the geometric objects (points, segments...) forming the triangulation together with a few geometric predicates and constructions on these objects.

Refines

TriangulationTraits_3

In addition to the requirements described for the traits class of *Triangulation_3*, the geometric traits class of a Delaunay triangulation must fulfill the following requirements:

Types

<i>DelaunayTriangulationTraits_3:: Line_3</i>	The line type.
<i>DelaunayTriangulationTraits_3:: Object_3</i>	The object type.
<i>DelaunayTriangulationTraits_3:: Ray_3</i>	The ray type.

DelaunayTriangulationTraits_3:: Coplanar_side_of_bounded_circle_3

A predicate object that must provide the function operator
Bounded_side operator()(Point p, Point q, Point r, Point s),
 which determines the bounded side of the circle defined by *p*, *q*, and *r* on which
s lies.

Precondition: *p*, *q*, *r*, and *s* are coplanar and *p*, *q*, and *r* are not collinear.

DelaunayTriangulationTraits_3:: Side_of_oriented_sphere_3

A predicate object that must provide the function operator
Oriented_side operator()(Point p, Point q, Point r, Point s, Point t),
 which determines on which side of the oriented sphere circumscribing *p*, *q*, *r*,
s the point *t* lies.

DelaunayTriangulationTraits_3:: Compare_distance_3

A predicate object that must provide the function operator
Comparison_result operator()(Point p, Point q, Point r),
 which compares the distance between *p* and *q* to the distance between *p* and *r*.
 It is only needed when using the *Fast_location* policy or the *nearest_vertex*
 function.

In addition, only when the dual operations are used, the traits class must provide the following constructor objects:

DelaunayTriangulationTraits_3:: Construct_circumcenter_3

A constructor object that must provide the function operator
Point_3 operator()(Point_3 p, Point_3 q, Point_3 r, Point_3 s),
which constructs the circumcenter of four points.

Precondition: *p, q, r* and *s* must be non coplanar.

It must also provide the function operator
Point_3 operator()(Point_3 p, Point_3 q, Point_3 r),
which constructs the circumcenter of three points.

Precondition: *p, q* and *r* must be non collinear.

DelaunayTriangulationTraits_3:: Construct_object_3

A constructor object that must provide the function operators
Object_3 operator()(Point_3 p),
Object_3 operator()(Segment_3 s) and
Object_3 operator()(Ray_3 r)
that construct an object respectively from a point, a segment and a ray.

DelaunayTriangulationTraits_3:: Construct_equidistant_line_3

A constructor object that must provide the function operator
Line_3 operator()(Point_3 p1, Point_3 p2, Point_3 p3),
which constructs the line which is at the same distance from the three points.
Precondition: *p1, p2* and *p3* must be non collinear.

DelaunayTriangulationTraits_3:: Construct_ray_3

A constructor object that must provide the function operator
Ray_3 operator()(Point_3 p, Line_3 l),
which constructs the ray starting at *p* with direction given by *l*.

Operations

The following functions give access to the predicate and construction objects:

<i>Coplanar_side_of_bounded_circle_3</i>	<i>traits.coplanar_side_of_bounded_circle_3_object()</i>
<i>Side_of_oriented_sphere_3</i>	<i>traits.side_of_oriented_sphere_3_object()</i>

When using the *Fast_location* policy or the *nearest_vertex* function, the traits must provide:

<i>Compare_distance_3</i>	<i>traits.compare_distance_3_object()</i>
---------------------------	---

The following functions must be provided only if the methods of *Delaunay_triangulation_3* returning elements of the Voronoi diagram are instantiated:

<i>Construct_circumcenter_3</i>	<i>traits.construct_circumcenter_3_object()</i>
<i>Construct_object_3</i>	<i>traits.construct_object_3_object()</i>
<i>Construct_perpendicular_line_3</i>	<i>traits.construct_perpendicular_line_object()</i>
<i>Construct_plane_3</i>	<i>traits.construct_plane_3_object()</i>
<i>Construct_ray_3</i>	<i>traits.construct_ray_3_object()</i>

Has Models

CGAL::Exact_predicates_inexact_constructions_kernel (recommended)

CGAL::Exact_predicates_exact_constructions_kernel (recommended for Voronoi)

CGAL::Filtered_kernel

CGAL::Cartesian

CGAL::Simple_cartesian

CGAL::Homogeneous

CGAL::Simple_homogeneous

RegularTriangulationTraits_3

Definition

The concept `RegularTriangulationTraits_3` is the first template parameter of the class *Regular_triangulation_3*. It defines the geometric objects (points, segments...) forming the triangulation together with a few geometric predicates and constructions on these objects.

Refines

TriangulationTraits_3

In addition to the requirements described for the traits class of *Triangulation_3*, the geometric traits class of *Regular_triangulation_3* must fulfill the following requirements.

Types

<i>RegularTriangulationTraits_3:: Line_3</i>	The line type.
<i>RegularTriangulationTraits_3:: Object_3</i>	The object type.
<i>RegularTriangulationTraits_3:: Plane_3</i>	The plane type.
<i>RegularTriangulationTraits_3:: Ray_3</i>	The ray type.

We use here the same notation as in Section 37.3. To simplify notation, p will often denote in the sequel either the point $p \in \mathbb{R}^3$ or the weighted point $p^{(w)} = (p, w_p)$.

<i>RegularTriangulationTraits_3:: Weighted_point_3</i>	The weighted point type.
--	--------------------------

RegularTriangulationTraits_3:: Power_test_3

A predicate object which must provide the following function operators:

Oriented_side operator()(*Weighted_point_3* *p*, *Weighted_point_3* *q*, *Weighted_point_3* *r*, *Weighted_point_3* *s*, *Weighted_point_3* *t*),

which performs the following:

Let $z(p, q, r, s)^{(w)}$ be the power sphere of the weighted points (p, q, r, s) . Returns

ON_ORIENTED_BOUNDARY if *t* is orthogonal to $z(p, q, r, s)^{(w)}$,

ON_NEGATIVE_SIDE if *t* lies outside the oriented sphere of center $z(p, q, r, s)$ and radius $\sqrt{w_{z(p,q,r,s)}^2 + w_t^2}$ (which is equivalent to $\Pi(t^{(w)}, z(p, q, r, s)^{(w)}) > 0$),

ON_POSITIVE_SIDE if *t* lies inside this oriented sphere.

Precondition: *p*, *q*, *r*, *s* are not coplanar. Note that with this definition, if all the points have a weight equal to 0, then $power_test_3(p, q, r, s, t) = side_of_oriented_sphere(p, q, r, s, t)$.

Oriented_side operator()(*Weighted_point_3* *p*, *Weighted_point_3* *q*, *Weighted_point_3* *r*, *Weighted_point_3* *t*),

which has an definition analogous to the previous method, for coplanar points, with the power circle $z(p, q, r)^{(w)}$.

Precondition: *p*, *q*, *r* are not collinear and *p*, *q*, *r*, *t* are coplanar. If all the points have a weight equal to 0, then $power_test_3(p, q, r, t) = side_of_oriented_circle(p, q, r, t)$.

Oriented_side operator()(*Weighted_point_3* *p*, *Weighted_point_3* *q*, *Weighted_point_3* *t*),

which is the same for collinear points, where $z(p, q)^{(w)}$ is the power segment of *p* and *q*.

Precondition: *p* and *q* have different Bare_points, and *p*, *q*, *t* are collinear. If all points have a weight equal to 0, then $power_test_3(p, q, t)$ gives the same answer as the kernel predicate $s(p, q).has_on(t)$ would give, where $s(p, q)$ denotes the segment with endpoints *p* and *q*.

Oriented_side operator()(*Weighted_point_3* *p*, *Weighted_point_3* *q*),

which is the same for equal points, that is when *p* and *q* have equal coordinates, then it returns the comparison of the weights (*ON_POSITIVE_SIDE* when *q* is heavier than *p*).

Precondition: *p* and *q* have equal Bare_points.

The following predicate is required if a call to *nearest_power_vertex* or *nearest_power_vertex_in_cell* is issued:

RegularTriangulationTraits_3:: Compare_power_distance_3

A predicate object that must provide the function operator

Comparison_result operator()(*Point_3* *p*, *Weighted_point_3* *q*, *Weighted_point_3* *r*),

which compares the power distance between *p* and *q* to the power distance between *p* and *r*.

In addition, only when the dual operations are used, the traits class must provide the following constructor objects:

RegularTriangulationTraits_3:: Construct_weighted_circumcenter_3

A constructor type. The operator() constructs the bare point which is the center of the smallest orthogonal sphere to the input weighted points.

Bare_point operator()(*Weighted_point_3* *p*, *Weighted_point_3* *q*, *Weighted_point_3* *r*, *Weighted_point_3* *s*);

RegularTriangulationTraits_3:: Construct_object_3

A constructor object that must provide the function operators
Object_3 operator()(Point_3 p),
Object_3 operator()(Segment_3 s) and
Object_3 operator()(Ray_3 r)
that construct an object respectively from a point, a segment and a ray.

RegularTriangulationTraits_3:: Construct_perpendicular_line_3

A constructor object that must provide the function operator
Line_3 operator()(Plane_3 pl, Point_3 p),
which constructs the line perpendicular to *pl* passing through *p*.

RegularTriangulationTraits_3:: Construct_plane_3

A constructor object that must provide the function operator
Plane_3 operator()(Point_3 p, Point_3 q, Point_3 r),
which constructs the plane passing through *p*, *q* and *r*.
Precondition: *p*, *q* and *r* are non collinear.

RegularTriangulationTraits_3:: Construct_ray_3

A constructor object that must provide the function operator
Ray_3 operator()(Point_3 p, Line_3 l),
which constructs the ray starting at *p* with direction given by *l*.

Operations

The following function gives access to the predicate object:

Power_test_3 *traits.power_test_3_object()*

The following functions must be provided only if the member functions of *Regular_triangulation_3* returning elements of the dual diagram are called:

Construct_weighted_circumcenter_3

traits.construct_weighted_circumcenter_3_object()

Construct_object_3 *traits.construct_object_3_object()*

Construct_perpendicular_line_3

traits.construct_perpendicular_line_object()

Construct_plane_3 *traits.construct_plane_3_object()*

Construct_ray_3 *traits.construct_ray_3_object()*

Has Models

CGAL::Regular_triangulation_euclidean_traits_3

CGAL::Regular_triangulation_euclidean_traits_3<K,Weight>

Definition

The class *Regular_triangulation_euclidean_traits_3<K,Weight>* is designed as a default traits class for the class *Regular_triangulation_3<RegularTriangulationTraits_3,TriangulationDataStructure_3>*. It provides *Weighted_point_3*, a class for weighted points, which derives from the three dimensional point class *K::Point_3*.

The first argument *K* must be a model of the *Kernel* concept.

The second argument *Weight* of the class *Regular_triangulation_euclidean_traits_3<K,Weight>* is in fact optional: if it is not provided, *K::RT* will be used.

The class is a model of the concept *RegularTriangulationTraits_3* but it also contains predicates and constructors on weighted points that are not required in the concept *RegularTriangulationTraits_3*.

Note that filtered predicates are automatically used if the boolean *Has_filtered_predicates* in the kernel provided as template parameter of that class is set to *true*.

```
#include <CGAL/Regular_triangulation_euclidean_traits_3.h>
```

Is Model for the Concepts

RegularTriangulationTraits_3

Inherits From

K

Types

<code>typedef K::Point_3</code>	<code>Bare_point;</code>	The type for point p of a weighted point $p^{(w)} = (p, w_p)$.
<code>typedef Weighted_point <Bare_point, Weight></code>	<code>Weighted_point_3;</code>	The type for weighted points.

Types for predicate functors

Regular_triangulation_euclidean_traits_3<K,Weight>:: Power_test_3

A predicate type for power test. Belongs to the *RegularTriangulationTraits_3* concept.

Regular_triangulation_euclidean_traits_3<K,Weight>:: Compare_power_distance_3

A predicate type to compare power distance. Belongs to the *RegularTriangulationTraits_3* concept.

Regular_triangulation_euclidean_traits_3<K,Weight>:: Compare_weighted_squared_radius_3

A predicate type. The operator() takes weighted point(s) as arguments, together with one weight. It compares the weight of the smallest sphere orthogonal to the weighted points with the input weight.

Comparison_result operator()(Weighted_point_3 p, Weighted_point_3 q, Weighted_point_3 r, Weighted_point_3 s, FT w) ;
Comparison_result operator()(Weighted_point_3 p, Weighted_point_3 q, Weighted_point_3 r, FT w) ;
Comparison_result operator()(Weighted_point_3 p, Weighted_point_3 q, FT w) ;
Comparison_result operator()(Weighted_point_3 p, FT w) ;

Regular_triangulation_euclidean_traits_3<K,Weight>:: In_smallest_orthogonal_sphere_3

A predicate type. The operator() takes weighted points as arguments and returns the sign of the power distance of the last one with respect to the smallest sphere orthogonal to the others.

Sign operator()(Weighted_point_3 p, Weighted_point_3 q, Weighted_point_3 r, Weighted_point_3 s, Weighted_point_3 t) ;
Sign operator()(Weighted_point_3 p, Weighted_point_3 q, Weighted_point_3 r, Weighted_point_3 s) ;
Sign operator()(Weighted_point_3 p, Weighted_point_3 q, Weighted_point_3 r) ;
Sign operator()(Weighted_point_3 p, Weighted_point_3 q) ;

Regular_triangulation_euclidean_traits_3<K,Weight>:: Side_of_bounded_orthogonal_sphere_3

A predicate type. The operator() is similar to the operator() of *In_smallest_orthogonal_sphere_3* except that the returned type is not a *Sign* but belongs to the enum *Bounded_side* (A *NEGATIVE*, *ZERO* and *POSITIVE*) corresponding respectively to *ON_BOUNDED_SIDE*, *ON_BOUNDARY* and *ON_UNBOUNDED_SIDE*)).

Bounded_side operator()(Weighted_point_3 p, Weighted_point_3 q, Weighted_point_3 r, Weighted_point_3 s, Weighted_point_3 t) ;
Bounded_side operator()(Weighted_point_3 p, Weighted_point_3 q, Weighted_point_3 r, Weighted_point_3 s) ;
Bounded_side operator()(Weighted_point_3 p, Weighted_point_3 q, Weighted_point_3 r) ;

Regular_triangulation_euclidean_traits_3<K,Weight>:: Does_simplex_intersect_dual_support_3

A predicate type. The operator() takes weighted points as arguments, considers the subspace of points with equal power distance with respect to its arguments and the intersection of this subspace with the affine hull of the bare points associated to the arguments. The operator() returns *ON_BOUNDED_SIDE*, *ON_BOUNDARY* or *ON_UNBOUNDED_SIDE* according to the position of this intersection with respect to the simplex formed by the bare points. This predicate is useful for flow computations.

Bounded_side operator()(Weighted_point_3 p, Weighted_point_3 q, Weighted_point_3 r, Weighted_point_3 s) ;
Bounded_side operator()(Weighted_point_3 p, Weighted_point_3 q, Weighted_point_3 r) ;
Bounded_side operator()(Weighted_point_3 p, Weighted_point_3 q) ;

Types for constructor functors

Regular_triangulation_euclidean_traits_3<K,Weight>:: Construct_weighted_circumcenter_3

A constructor type. The operator() constructs the bare point which is the center of the smallest orthogonal sphere to the input weighted points.

Bare_point operator() (*Weighted_point_3 p*, *Weighted_point_3 q*, *Weighted_point_3 r*, *Weighted_point_3 s*);

Bare_point operator() (*Weighted_point_3 p*, *Weighted_point_3 q*, *Weighted_point_3 r*);

Bare_point operator() (*Weighted_point_3 p*, *Weighted_point_3 q*);

Regular_triangulation_euclidean_traits_3<K,Weight>:: Compute_power_product_3

A functor type. The operator() computes the power distance between its arguments.

FT operator() (*Weighted_point_3 p*, *Weighted_point_3 q*);

Regular_triangulation_euclidean_traits_3<K,Weight>:: Compute_squared_radius_smallest_orthogonal_sphere_3

A functor type. The operator() computes the squared radius of the smallest sphere orthogonal to the argument(s).

FT operator() (*Weighted_point_3 p*, *Weighted_point_3 q*, *Weighted_point_3 r*, *Weighted_point_3 s*);

FT operator() (*Weighted_point_3 p*, *Weighted_point_3 q*, *Weighted_point_3 r*);

FT operator() (*Weighted_point_3 p*, *Weighted_point_3 q*);

FT operator() (*Weighted_point_3 p*);

Regular_triangulation_euclidean_traits_3<K,Weight>:: Compute_critical_squared_radius_3

A functor type. The operator() takes weighted points as arguments and computes the squared radius of the sphere centered in the last point and orthogonal to the other weighted points. The last argument is a weighted point but its weight does not matter. This construction is ad hoc for pumping slivers. For robustness issue, a predicate to compare critical squared radii for a given last point should be needed.

FT operator() (*Weighted_point_3 p*, *Weighted_point_3 q*, *Weighted_point_3 r*, *Weighted_point_3 s*, *Weighted_point_3 t*);

Operations

The following functions give access to the predicate and constructor functors.

Power_test_3

traits.power_test_3_object()

Compare_power_distance_3

traits.compare_power_distance_3_object()

Compare_weighted_squared_radius_3

traits.compare_weighted_squared_radius_3_object()

object() *traits.compute_squared_radius_smallest_orthogonal_sphere_3_*

Compute_critical_squared_radius_3 *traits.compute_critical_squared_radius_3_object()*

TriangulationCellBase_3

Definition

The cell base required by the basic triangulation does not need to store any geometric information, so only the requirements of the triangulation data structure apply.

However, for the Delaunay triangulation, the ability to store the circumcenter is provided (for optimization reasons), hence an additional requirement only in this case, and only when the dual functions are called.

Refines

TriangulationDSCellBase_3

DelaunayTriangulationTraits_3::Point_3

```
3() c.circumcenter( DelaunayTriangulationTraits_3 gt = DelaunayTriangulationTraits_3())
```

Returns the circumcenter.

TriangulationVertexBase_3

TriangulationVertexBase_3

Definition

The vertex base used by the geometric triangulation must store a point. So we list here the additional requirements compared to a vertex base usable for the triangulation data structure.

Refines

TriangulationDSVertexBase_3

Types

TriangulationVertexBase_3::Point

Must be the same as the point type *TriangulationTraits_3::Point_3* defined by the geometric traits class of the triangulation.

Creation

TriangulationVertexBase_3 *v*(*Point* *p*);

Constructs a vertex whose geometric embedding is point *p*.

TriangulationVertexBase_3 *v*(*Point* *p*, *Cell_handle* *c*);

Constructs a vertex embedding the point *p* and pointing to cell *c*.

Access Functions

Point *v.point()*

Returns the point.

Setting

void *v.set_point(Point* *p*)

Sets the point.

I/O

istream& *istream& is >> &v*

Inputs the non-combinatorial information given by the vertex: the point and other possible information.

ostream& *ostream& os << v*

Outputs the non-combinatorial information given by the vertex: the point and other possible information.

TriangulationCellBase_3

CGAL::Triangulation_simplex_3<Triangulation_3>

Definition

The class *Triangulation_simplex_3<Triangulation_3>* stores a simplex of any dimension defined by the *Triangulation_3* class. It also defines the operator less such that simplices can be stored in a *map* or a *set* of simplices. The simplex is invalidated by any change in the triangulation.

```
#include <CGAL/Triangulation_simplex_3.h>
```

Parameters

It is parameterized by the triangulation it derives the simplices from.

Types

```
typedef Triangulation_simplex_3<Triangulation_3>   Simplex;           The simplex class itself.
```

```
typedef Triangulation_3::Vertex_handle             Vertex_handle;
typedef Triangulation_3::Edge                     Edge;
typedef Triangulation_3::Facet                     Facet;
typedef Triangulation_3::Cell_handle               Cell_handle;
```

```
typedef Triangulation_3::Cell_circulator           Cell_circulator;
typedef Triangulation_3::Facet_circulator          Facet_circulator;
```

```
typedef Triangulation_3::Edge_iterator             Edge_iterator;
typedef Triangulation_3::Facet_iterator            Facet_iterator;
```

```
typedef Triangulation_3::Finite_vertices_iterator Finite_vertices_iterator;
typedef Triangulation_3::Finite_edges_iterator    Finite_edges_iterator;
typedef Triangulation_3::Finite_facets_iterator   Finite_facets_iterator;
typedef Triangulation_3::Finite_cells_iterator    Finite_cells_iterator;
```

Creation

```
Triangulation_simplex_3<Triangulation_3> simplex;    Initializes the simplex to an invalid simplex.
```

```
Triangulation_simplex_3<Triangulation_3> simplex( Vertex_handle vh);
Triangulation_simplex_3<Triangulation_3> simplex( Edge e);
Triangulation_simplex_3<Triangulation_3> simplex( Facet f);
Triangulation_simplex_3<Triangulation_3> simplex( Cell_handle ch);
```

```
Triangulation_simplex_3<Triangulation_3> simplex( Cell_circulator ccir);
Triangulation_simplex_3<Triangulation_3> simplex( Facet_circulator fcir);
```

```

Triangulation_simplex_3<Triangulation_3> simplex( Edge_iterator eit);
Triangulation_simplex_3<Triangulation_3> simplex( Facet_iterator fit);

```

Operations

<i>int</i>	<i>simplex.dimension()</i>	returns the dimension of the simplex.
<i>Vertex_handle</i>	<i>Vertex_handle (simplex)</i>	Returns the <i>Vertex_handle</i> stored in the simplex. <i>Precondition:</i> <i>dimension() == 0</i>
<i>Edge</i>	<i>Edge (simplex)</i>	Returns the <i>Edge</i> stored in the simplex. <i>Precondition:</i> <i>dimension() == 1</i>
<i>Facet</i>	<i>Facet (simplex)</i>	Returns the <i>Facet</i> stored in the simplex. <i>Precondition:</i> <i>dimension() == 2</i>
<i>Cell_handle</i>	<i>Cell_handle (simplex)</i>	Returns the <i>Cell_handle</i> stored in the simplex. <i>Precondition:</i> <i>dimension() == 3</i>
<i>Cell_handle</i>	<i>simplex.incident_cell()</i>	Returns a cell incident to the simplex.
<i>bool</i>	<i>simplex == s1</i>	Test whether two simplices are equal.
<i>bool</i>	<i>simplex < s1</i>	Defines a ordering on the simplices. This ordering depends on the memory layout and is independent of the geometry. Therefore, the ordering is not intrinsic

— deprecated —

RegularTriangulationCellBase_3

Definition

The regular triangulation of a set of weighted points does not necessarily have one vertex for each of the input points. Some of the input weighted points have no cell in the dual power diagrams and therefore do not correspond to a vertex of the regular triangulation. Those weighted points are said to be *hidden* points. A point which is hidden at a given time may appear later as a vertex of the regular triangulation upon removal of some other weighted point. Therefore, hidden points have to be stored somewhere. The regular triangulation stores those hidden points in its cells.

A hidden point can appear as vertex of the triangulation only when the three dimensional cell where its point component is located (the cell which hides it) is removed. Therefore we decided to store in each cell of a regular triangulation the list of hidden points that are located in the face. Thus points hidden by a face are easily reinserted in the triangulation when the face is removed.

The base cell of a regular triangulation has to be a model of the concept `RegularTriangulationCellBase_3`, which refines the concept *TriangulationCellBase_3* by adding in the cell a container to store hidden points.

Refines

TriangulationCellBase_3

Types

<i>RegularTriangulationCellBase_3:: Point</i>	Must be the same as the point type <i>TriangulationTraits_3::Point_3</i> defined by the geometric traits class of the triangulation.
---	--

Types

<i>RegularTriangulationCellBase_3:: Point_iterator</i>	Iterator of value type <code>Point</code>
--	---

Access Functions

<i>Point_iterator</i>	<i>rcb.hidden_points_begin()</i>	Returns an iterator pointing to the first hidden point.
-----------------------	----------------------------------	---

<i>Point_iterator</i>	<i>rcb.hidden_points_end()</i>	Returns a past-the-end iterator.
-----------------------	--------------------------------	----------------------------------

Setting

void *rcb.hide_point(Point p)*

Adds p to the set of hidden points of the cell.

CGAL::Triangulation_cell_base_3<TriangulationTraits_3, TriangulationDSCellBase_3>

Definition

The class *Triangulation_cell_base_3* is a model of the concept *TriangulationCellBase_3*, the base cell of a 3D-triangulation.

This class can be used directly or can serve as a base to derive other classes with some additional attributes (a color for example) tuned for a specific application.

```
#include <CGAL/Triangulation_cell_base_3.h>
```

Parameters

The first template argument is the geometric traits class *TriangulationTraits_3*. It is actually not used by this class.

The second template argument is a combinatorial cell base class from which *Triangulation_cell_base_3* derives. It has the default value *Triangulation_ds_cell_base_3*<>.

Note that this model does not store the circumcenter, but computes it every time the circumcenter function is called. See *CGAL::Triangulation_cell_base_with_circumcenter_3* for a way to cache the circumcenter computation.

WeightedPoint

Definition

The concept `WeightedPoint` is needed by *Regular_triangulation_euclidean_traits_3*. It must fulfill the following requirements:

Types

<i>WeightedPoint::Point</i>	The point type
<i>WeightedPoint::Weight</i>	The weight type
<i>typedef Point::RT RT;</i>	The ring type

Creation

WeightedPoint wp(Point p=Point(), Weight w = Weight(0));

Access Functions

<i>Point</i>	<i>point()</i>
<i>Weight</i>	<i>weight()</i>

Has Models

Weighted_point.

CGAL::Regular_triangulation_filtered_traits_3<FK>

— deprecated —

Note : this class is deprecated since CGAL 3.6. The class *CGAL::Regular_triangulation_euclidean_traits_3* should be used instead. Filtered predicates are automatically used if the boolean *Has_filtered_predicates* in the kernel provided as template parameter of that class is set to *true*.

Definition

The class *Regular_triangulation_filtered_traits_3<FK>* is designed as a traits class for the class *Regular_triangulation_3<RegularTriangulationTraits_3,TriangulationDataStructure_3>*. Its difference with *Regular_triangulation_euclidean_traits_3* is that it provides filtered predicates which are meant to be fast and exact.

The first argument *FK* must be a model of the *Kernel* concept, and it is also restricted to be a instance of the *Filtered_kernel* template.

```
#include <CGAL/Regular_triangulation_filtered_traits_3.h>

A geometric triangulation has two aspects: the combinatorial structure, which gives the incidence and adjacency relations between faces, and the geometric information related to the position of vertices.

CGAL provides 3D geometric triangulations in which these two aspects are clearly separated. As described in Chapter 37, a geometric triangulation of a set of points in \mathbb{R}^d , $d \leq 3$ is a partition of the whole space \mathbb{R}^d into cells having $d + 1$ vertices. Some of them are infinite, they are obtained by linking an additional vertex at infinity to each facet of the convex hull of the points (see Section 37.1). The underlying combinatorial graph of such a triangulation without boundary of \mathbb{R}^d can be seen as a triangulation of the topological sphere S^d in \mathbb{R}^{d+1} .

This chapter deals with 3D-triangulation data structures, meant to maintain the combinatorial information for 3D-geometric triangulations. The reader interested in geometric triangulations of \mathbb{R}^3 is advised to read Chapter 37.

38.1 Representation

In CGAL, a 3D triangulation data structure is a container of cells (3-faces) and vertices (0-faces).

Following the standard vocabulary of simplicial complexes, an i -face f_i and a j -face f_j ($0 \leq j < i \leq 3$) are said to be *incident* in the triangulation if f_j is a (sub)face of f_i , and two i -faces ($0 \leq i \leq 3$) are said to be *adjacent* if they share a common incident (sub)face.

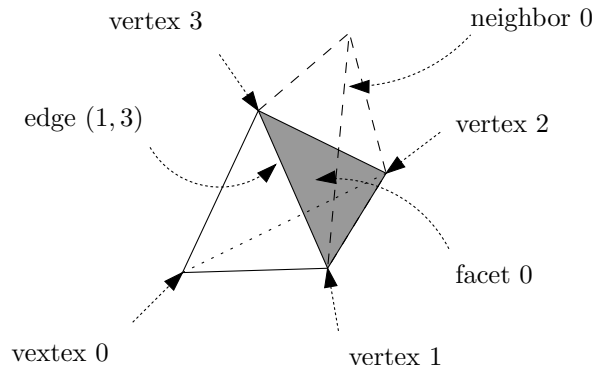

Figure 38.1: Representation.

Each cell gives access to its four incident vertices and to its four adjacent cells. Each vertex gives direct access to one of its incident cells, which is sufficient to retrieve all the incident cells when needed.

The four vertices of a cell are indexed with 0, 1, 2 and 3. The neighbors of a cell are also indexed with 0, 1, 2, 3 in such a way that the neighbor indexed by i is opposite to the vertex with the same index (see Figure 38.1).

Edges (1-faces) and facets (2-faces) are not explicitly represented: a facet is given by a cell and an index (the facet i of a cell c is the facet of c that is opposite to the vertex of index i) and an edge is given by a cell and two indices (the edge (i,j) of a cell c is the edge whose endpoints are the vertices of indices i and j of c).

Degenerate Dimensions As CGAL explicitly deals with all degenerate cases, a 3D-triangulation data structure in CGAL can handle the cases when the dimension of the triangulation is lower than 3.

Thus, a 3D-triangulation data structure can store a triangulation of a topological sphere S^d of \mathbb{R}^{d+1} , for any $d \in \{-1, 0, 1, 2, 3\}$.

Let us give, for each dimension, the example corresponding to the triangulation data structure having a minimal number of vertices, i.e. a simplex. These examples are illustrated by presenting their usual geometric embedding.

- *dimension 3.* The triangulation data structure consists of the boundary of a 4-dimensional simplex, which has 5 vertices. A geometric embedding consists in choosing one of these vertices to be infinite, thus four of the five 3-cells become infinite: the geometric triangulation has one finite tetrahedron remaining, each of its facets being incident to an infinite cell. See Figure 38.2.
- *dimension 2.* We have 4 vertices forming one 3-dimensional simplex, i.e. the boundary of a tetrahedron. The geometric embedding in the plane results from choosing one of these vertices to be infinite, then the geometric triangulation has one finite triangle whose edges are incident to the infinite triangles. See Figure 38.3.
- *dimension 1.* A 2-dimensional simplex (a triangle) has 3 vertices. The geometric embedding is an edge whose vertices are linked to an infinite point. See Figure 38.4.

The last three cases are defined uniquely:

- *dimension 0.* A 0-dimensional triangulation is combinatorially equivalent to the boundary of a 1-dimensional simplex (an edge), which consists of 2 vertices. One of them becomes infinite in the geometric embedding, and there is only one finite vertex remaining. The two vertices are adjacent.

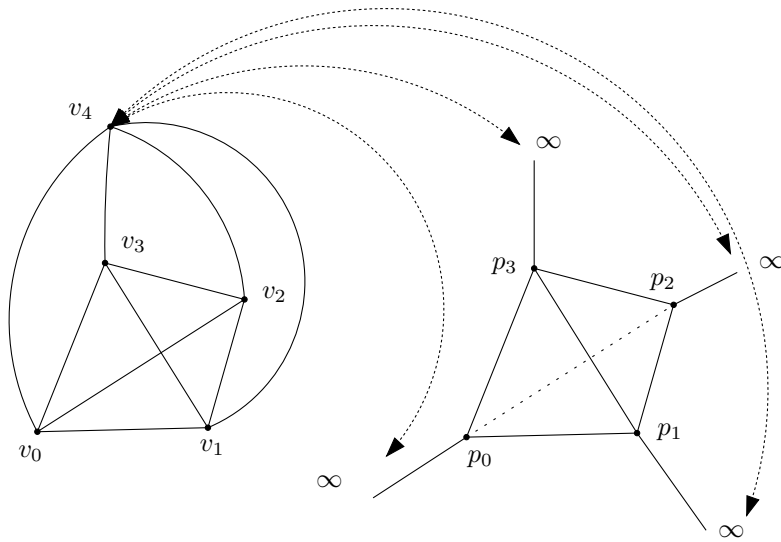

Figure 38.2: 4D simplex and a 3D geometric embedding.

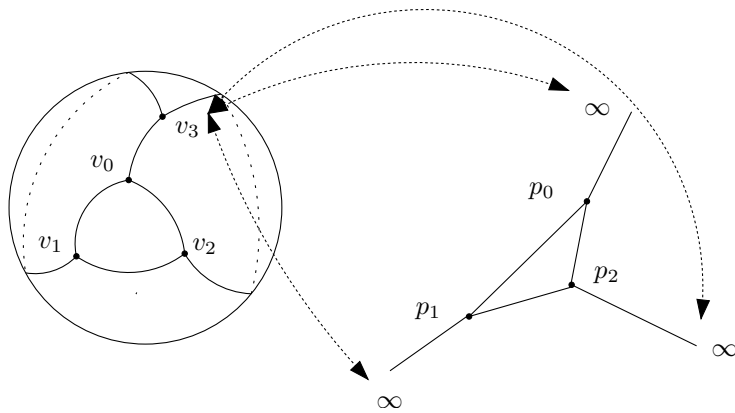

Figure 38.3: 3D simplex and a 2D geometric embedding.

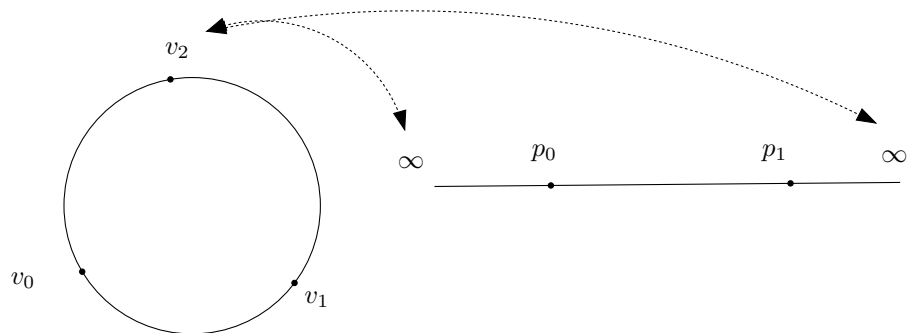

Figure 38.4: 2D simplex and a 1D geometric embedding.

- *dimension -1*. This dimension is a convention to represent a 0-dimensional simplex, that is a sole vertex, which will be geometrically embedded as an “empty” triangulation, having only one infinite vertex.
- *dimension -2*. This is also a convention. The triangulation data structure has no vertex. There is no associated geometric triangulation.

Note that the notion of infinite vertex has no meaning for the triangulation data structure. The infinite vertex of the geometric embedding is a vertex that cannot be distinguished from the other vertices in the combinatorial triangulation.

The same cell class is used in all cases: triangular faces in 2D can be considered as degenerate cells, having only three vertices (resp. neighbors) numbered (0, 1, 2); edges in 1D have only two vertices (resp. neighbors) numbered 0 and 1.

The implicit representation of facets (resp. edges) still holds for degenerate (< 3) dimensions : in dimension 2, each cell has only one facet of index 3, and 3 edges (0, 1), (1, 2) and (2, 0); in dimension 1, each cell has one edge (0, 1).

Validity A 3D combinatorial triangulation is said to be *locally valid* iff the following is true:

(a) When a cell c has a neighbor pointer to another cell c' , then reciprocally this cell c' has a neighbor pointer to c , and c and c' have three vertices in common. These cells are called adjacent.

(b) The cells have a coherent orientation: if two cells c_1 and c_2 are adjacent and share a facet with vertices u, v, w , then the vertices of c_1 are numbered ($v_0^1 = u, v_1^1 = v, v_2^1 = w, v_3^1$), and the vertices of c_2 are numbered ($v_0^2 = v, v_1^2 = u, v_2^2 = w, v_3^2$), up to positive permutations of (0, 1, 2, 3). In other words, if we embed the triangulation in \mathbb{R}^3 , then the fourth vertices v_3^1 and v_3^2 of c_1 and c_2 see the common facet in opposite orientations. See Figure 38.5.

The set \mathfrak{S}_4 of permutations of (0, 1, 2, 3) has cardinality 24, and the set of positive permutations A_4 has cardinality 12. Thus, for a given orientation, there are up to 12 different orderings of the four vertices of a cell. Note that cyclic permutations are negative and so do not preserve the orientation of a cell.

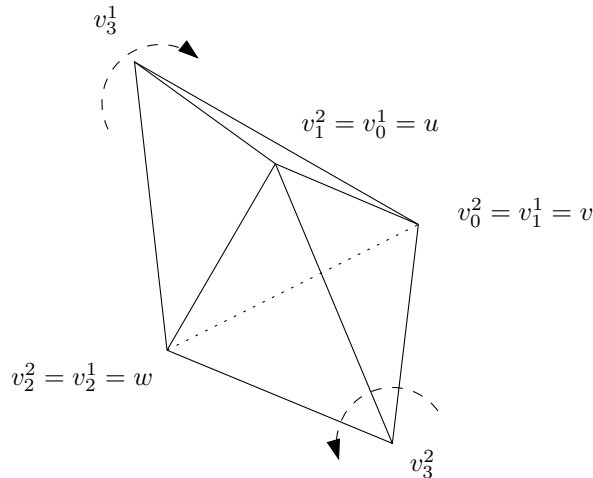

Figure 38.5: Coherent orientations of two cells (3-dimensional case).

The `is_valid()` method provided by `Triangulation_data_structure_3` checks the local validity of a given triangulation data structure.

38.2 Software Design

The 3D-triangulation data structure class of CGAL, *Triangulation_data_structure_3*, is designed to be used as a combinatorial layer upon which a geometric layer can be built [Ket98]. This geometric layer is typically one of the 3D-triangulation classes of CGAL: *Triangulation_3*, *Delaunay_triangulation_3* and *Regular_triangulation_3*. This relation is described in more details in Chapter 37, where the Section 37.4 explains other important parts of the design related to the geometry.

We focus here on the design of the triangulation data structure (TDS) itself, which the Figure 38.6 illustrates.

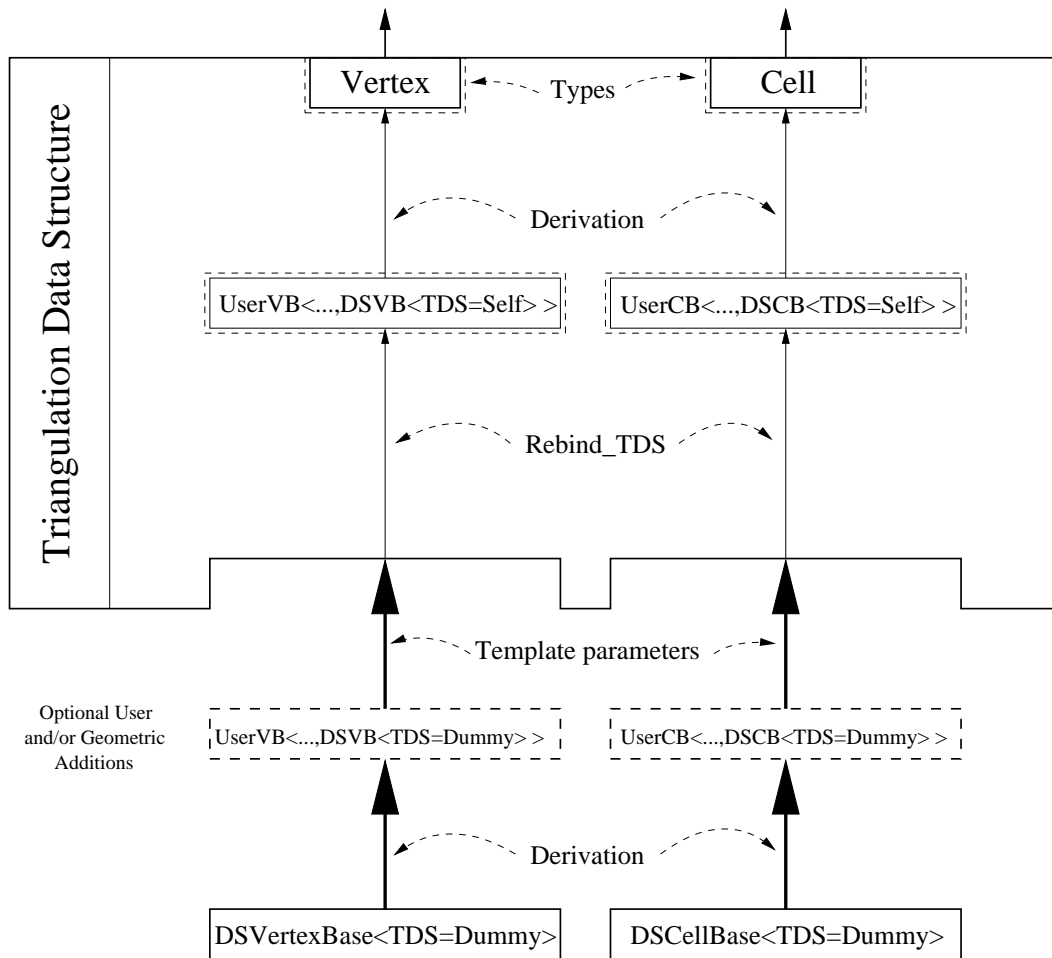

Figure 38.6: Triangulation Data Structure software design.

38.2.1 Flexibility of the Design

In order for the user to be able to add his own data in the vertices and cells, the design of the TDS is split into two layers:

- In the bottom layer, the (vertex and cell) base classes store elementary incidence and adjacency (and possibly geometric or other) information. These classes are parameterized by the TDS which provides

the handle types. (They can also be parameterized by a geometric traits class or anything else.) A vertex stores a *Cell_handle*, and a cell stores four *Vertex_handles* and four *Cell_handles*.

- The middle layer is the TDS, which is purely combinatorial. It provides operations such as insertion of a new vertex in a given cell, on a 1 or 2-face. It also allows one, if the dimension of the triangulation is smaller than 3, to insert a vertex so that the dimension of the triangulation is increased by one. The TDS is responsible for the combinatorial integrity of the eventual geometric triangulation built on top of it (the upper layer, see Chapter 37).

The user has several ways to add his own data in the vertex and cell base classes used by the TDS. He can either:

- use the classes *Triangulation_vertex_base_with_info* and *Triangulation_cell_base_with_info*, which allow to add one data member of a user provided type, and give access to it.
- derive his own classes from the default base classes *Triangulation_ds_vertex_base*, and *Triangulation_ds_cell_base* (or the geometric versions typically used by the geometric layer, *Triangulation_vertex_base*, and *Triangulation_cell_base*).
- write his own base classes following the requirements given by the concepts *TriangulationCellBase_3* and *TriangulationVertexBase_3* (described in page 2512 and page 2513).

38.2.2 Cyclic Dependency

Since adjacency relations are stored in the vertices and cells, it means that the vertex and cell base classes have to be able to store handles (an entity akin to pointers) to their neighbors in the TDS. This in turns means that the vertex and cell base classes have to know the types of these handles, which are provided by the TDS. So in a sense, the base classes are parameterized by the TDS, and the TDS is parameterized by the vertex and cell base classes ! This is a cycle which cannot be resolved easily.

The solution that we have chosen is similar to the mechanism used by the standard class *std::allocator*: the vertex and cell base classes are initially given a fake or dummy TDS template parameter, whose unique purpose is to provide the types that can be used by the vertex and cell base classes (such as handles). Then, inside the TDS itself, these base classes are *rebound* to the real TDS type, that is we obtain the same vertex and cell base classes, but parameterized with the real TDS instead of the dummy one. Rebinding is performed by a nested template class of the vertex and cell base classes (see code below), which provides a type which is the rebound vertex or cell base class¹.

Here is how it works, schematically:

```
template < class Vb, class Cb >
class TDS
{
    typedef TDS<Vb, Cb>      Self;

    // Rebind the vertex and cell base to the actual TDS (Self).
    typedef typename Vb::template Rebind_TDS<Self>::Other  VertexBase;
    typedef typename Cb::template Rebind_TDS<Self>::Other  CellBase;

    // ... further internal machinery leads to the final public types:
public:
    typedef ...  Vertex;
    typedef ...  Cell;
```

¹It is logically equivalent to a mechanism that does not exist yet in the C++ language: *template typedef* or *template aliasing*

```

typedef ... Vertex_handle;
typedef ... Cell_handle;
};

template < class TDS = ... > // The default is some internal type faking
    a TDS
class Triangulation_ds_vertex_base_3
{
public:
    template < class TDS2 >
    struct Rebind_TDS {
        typedef Triangulation_ds_vertex_base_3<TDS2>    Other;
    };
    ...
};

```

When derivation is used for the vertex or cell base classes, which is the case at the geometric level with *Triangulation_vertex_base_3*, then it gets slightly more involved because its base class has to be rebound as well:

```

template < class GT, class Vb = Triangulation_ds_vertex_base_3<> >
class Triangulation_vertex_base_3 : public Vb
{
public:
    template < class TDS2 >
    struct Rebind_TDS {
        typedef typename Vb::template Rebind_TDS<TDS2>::Other    Vb2;
        typedef Triangulation_vertex_base_3<GT, Vb2>            Other;
    };
    ...
};

```

38.3 Examples

38.3.1 Incremental Construction

The following example shows how to construct a 3D triangulation data structure by inserting vertices.

```

#include <CGAL/Triangulation_data_structure_3.h>
#include <iostream>
#include <fstream>
#include <cassert>
#include <vector>

typedef CGAL::Triangulation_data_structure_3<>    Tds;

typedef Tds::size_type                            size_type;
typedef Tds::Cell_handle                          Cell_handle;
typedef Tds::Vertex_handle                        Vertex_handle;

int main()

```

```

{
    Tds T;

    assert( T.number_of_vertices() == 0 );
    assert( T.dimension() == -2 );
    assert( T.is_valid() );

    std::vector<Vertex_handle> PV(7);

    PV[0] = T.insert_increase_dimension();
    assert( T.number_of_vertices() == 1 );
    assert( T.dimension() == -1 );
    assert( T.is_valid() );

    // each of the following insertions of vertices increases the dimension
    for ( int i=1; i<5; i++ ) {
        PV[i] = T.insert_increase_dimension(PV[0]);
        assert( T.number_of_vertices() == (size_type) i+1 );
        assert( T.dimension() == i-1 );
        assert( T.is_valid() );
    }
    assert( T.number_of_cells() == 5 );

    // we now have a simplex in dimension 4

    // cell incident to PV[0]
    Cell_handle c = PV[0]->cell();
    int ind;
    bool check = c->has_vertex( PV[0], ind );
    assert( check );
    // PV[0] is the vertex of index ind in c

    // insertion of a new vertex in the facet opposite to PV[0]
    PV[5] = T.insert_in_facet(c, ind);

    assert( T.number_of_vertices() == 6 );
    assert( T.dimension() == 3 );
    assert( T.is_valid() );

    // insertion of a new vertex in c
    PV[6] = T.insert_in_cell(c);

    assert( T.number_of_vertices() == 7 );
    assert( T.dimension() == 3 );
    assert( T.is_valid() );

    std::ofstream oFileT("output_tds",std::ios::out);
    // writing file output_tds;
    oFileT << T;

    return 0;
}

```

38.3.2 Cross-Linking Between a 2D and a 3D Data Structures

This example program illustrates how to setup a 2D and a 3D triangulation data structures whose vertices respectively store vertex handles of the other one.

```
#include <CGAL/Triangulation_data_structure_2.h>
#include <CGAL/Triangulation_data_structure_3.h>
#include <cassert>

// declare the 2D vertex base type, parametrized by some 3D TDS.
template < typename T3, typename Vb =
    CGAL::Triangulation_ds_vertex_base_2<> >
class My_vertex_2;

// declare the 3D vertex base type, parametrized by some 2D TDS.
template < typename T2, typename Vb =
    CGAL::Triangulation_ds_vertex_base_3<> >
class My_vertex_3;

// Then, we have to break the dependency cycle.

// we need to refer to a dummy 3D TDS.
typedef
    CGAL::Triangulation_ds_vertex_base_3<>::Triangulation_data_structure
    Dummy_tds_3;
// the 2D TDS, initially plugging a dummy 3D TDS in the vertex type
// (to break the dependency cycle).
typedef CGAL::Triangulation_data_structure_2<My_vertex_2<Dummy_tds_3> >
    TDS_2;
// the 3D TDS, here we can plug the 2D TDS directly.
typedef CGAL::Triangulation_data_structure_3<My_vertex_3<TDS_2> >
    TDS_3;

template < typename T3, typename Vb >
class My_vertex_2
: public Vb
{
public:
    typedef typename Vb::Face_handle    Face_handle;

    template <typename TDS2>
    struct Rebind_TDS {
        typedef typename Vb::template Rebind_TDS<TDS2>::Other    Vb2;
        // we also have to break the cycle here by hardcoding TDS_3 instead
        // of T3.
        typedef My_vertex_2<TDS_3, Vb2>                                Other;
    };

    My_vertex_2() {}
};
```

```

My_vertex_2(Face_handle f) : Vb(f) {}

// we store a vertex handle of the 3D TDS.
typename T3::Vertex_handle v3;
};

template < typename T2, typename Vb >
class My_vertex_3
: public Vb
{
public:
    typedef typename Vb::Cell_handle    Cell_handle;

    template <typename TDS2>
    struct Rebind_TDS {
        typedef typename Vb::template Rebind_TDS<TDS2>::Other    Vb2;
        typedef My_vertex_3<T2, Vb2>                               Other;
    };

    My_vertex_3() {}

    My_vertex_3(Cell_handle c) : Vb(c) {}

    // we store a vertex handle of the 2D TDS.
    typename T2::Vertex_handle v2;
};

int main() {
    TDS_2 t2;
    TDS_3 t3;

    TDS_2::Vertex_handle v2 = t2.insert_dim_up();
    TDS_3::Vertex_handle v3 = t3.insert_increase_dimension();

    v2->v3 = v3;
    v3->v2 = v2;

    assert(t2.is_valid());
    assert(t3.is_valid());
    return 0;
}

```

38.4 Design and Implementation History

Monique Teillaud introduced the triangulation of the topological sphere S^d in \mathbb{R}^{d+1} to manage the underlying graph of geometric triangulations and handle degenerate dimensions [Tei99].

Sylvain Pion improved the software in several ways, in particular regarding the memory management.

3D Triangulation Data Structure Reference Manual

Sylvain Pion and Monique Teillaud

The triangulation data structure is able to represent a triangulation of a topological sphere S^d of \mathbb{R}^{d+1} , for $d \in \{-1, 0, 1, 2, 3\}$. (See [38.1](#).)

The vertex class of a 3D-triangulation data structure must define a number of types and operations. The requirements that are of geometric nature are required only when the triangulation data structure is used as a layer for the geometric triangulation classes. (See [Section 38.2](#).)

The cell class of a triangulation data structure stores four handles to its four vertices and four handles to its four neighbors. The vertices are indexed 0, 1, 2, and 3 in a consistent order. The neighbor indexed i lies opposite to vertex i .

In degenerate dimensions, cells are used to store faces of maximal dimension: in dimension 2, each cell represents only one facet of index 3, and 3 edges (0,1), (1,2) and (2,0); in dimension 1, each cell represents one edge (0,1). (See [Section 38.1](#).)

TriangulationDataStructure_3

Definition

3D-triangulation data structures are meant to maintain the combinatorial information for 3D-geometric triangulations.

In CGAL, a triangulation data structure is a container of cells (3-faces) and vertices (0-faces). Following the standard vocabulary of simplicial complexes, an i -face f_i and a j -face f_j ($0 \leq j < i \leq 3$) are said to be *incident* in the triangulation if f_j is a (sub)face of f_i , and two i -faces ($0 \leq i \leq 3$) are said to be *adjacent* if they share a common incident (sub)face.

Each cell gives access to its four incident vertices and to its four adjacent cells. Each vertex gives direct access to one of its incident cells, which is sufficient to retrieve all the incident cells when needed.

The four vertices of a cell are indexed with 0, 1, 2 and 3. The neighbors of a cell are also indexed with 0, 1, 2, 3 in such a way that the neighbor indexed by i is opposite to the vertex with the same index (see Figure 38.1).

Edges (1-faces) and facets (2-faces) are not explicitly represented: a facet is given by a cell and an index (the facet i of a cell c is the facet of c that is opposite to the vertex of index i) and an edge is given by a cell and two indices (the edge (i,j) of a cell c is the edge whose endpoints are the vertices of indices i and j of c).

As CGAL explicitly deals with all degenerate cases, a 3D-triangulation data structure in CGAL can handle the cases when the dimension of the triangulation is lower than 3 (see Section 38.1).

Thus, a 3D-triangulation data structure can store a triangulation of a topological sphere S^d of \mathbb{R}^{d+1} , for any $d \in \{-1, 0, 1, 2, 3\}$.

The second template parameter of the basic triangulation class (see Chapter 37, page 2466) *Triangulation_3* is a triangulation data structure class. (See Chapter 38.)

To ensure all the **flexibility** of the class *Triangulation_3*, a model of a triangulation data structure must be templated by the base vertex and the base cell classes (see 38.1): *TriangulationDataStructure_3* < *TriangulationVertexBase_3*, *TriangulationCellBase_3* >. The optional functionalities related to geometry are compulsory for this use as a template parameter of *Triangulation_3*.

A class that satisfies the requirements for a triangulation data structure class must provide the following types and operations.

Types

TriangulationDataStructure_3::Vertex

Vertex type

TriangulationDataStructure_3::Cell

Cell type

TriangulationDataStructure_3::size_type

Size type (unsigned integral type)

TriangulationDataStructure_3::difference_type

Difference type (signed integral type)

Vertices and cells are usually manipulated via *handles*, which support the two dereference operators *operator** and *operator->*.

TriangulationDataStructure_3:: Vertex_handle
TriangulationDataStructure_3:: Cell_handle

Requirements for *Vertex* and *Cell* are described in *TriangulationDataStructure_3::Vertex* and *TriangulationDataStructure_3::Cell* (page 2559 and page 2557).

————— *advanced* —————

TriangulationDataStructure_3:: template <typename Vb2> struct Rebind_vertex

This nested template class allows to get the type of a triangulation data structure that only changes the vertex type. It has to define a type *Other* which is a *rebound* triangulation data structure, that is, the one whose *TriangulationDSVertexBase_3* will be *Vb2*.

TriangulationDataStructure_3:: template <typename Cb2> struct Rebind_cell

This nested template class allows to get the type of a triangulation data structure that only changes the cell type. It has to define a type *Other* which is a *rebound* triangulation data structure, that is, the one whose *TriangulationDSCellBase_3* will be *Cb2*.

————— *advanced* —————

<i>typedef Triple<Cell_handle, int, int></i>	<i>Edge;</i>	(<i>c,i,j</i>) is the edge of cell <i>c</i> whose vertices indices are <i>i</i> and <i>j</i> . (See Section 38.1.)
<i>typedef std::pair<Cell_handle, int></i>	<i>Facet;</i>	(<i>c,i</i>) is the facet of <i>c</i> opposite to the vertex of index <i>i</i> . (See Section 38.1.)

The following iterators allow one to visit all the vertices, edges, facets and cells of the triangulation data structure. They are all bidirectional, non-mutable iterators.

TriangulationDataStructure_3:: Cell_iterator
TriangulationDataStructure_3:: Facet_iterator
TriangulationDataStructure_3:: Edge_iterator
TriangulationDataStructure_3:: Vertex_iterator

The following circulators allow us to visit all the cells and facets incident to a given edge. They are bidirectional and non-mutable.

TriangulationDataStructure_3:: Facet_circulator
TriangulationDataStructure_3:: Cell_circulator

Iterators and circulators are convertible to the corresponding handles, thus the user can pass them directly as arguments to the functions.

Creation

<i>TriangulationDataStructure_3 tds;</i>	Default constructor.
--	----------------------

<i>TriangulationDataStructure_3</i>	<i>tds</i> (<i>tds1</i>);	Copy constructor. All vertices and cells are duplicated.
<i>TriangulationDataStructure_3</i> &	<i>tds</i> = <i>tds1</i>	Assignment operator. All vertices and cells are duplicated, and the former data structure of <i>tds</i> is deleted.
<i>Vertex_handle</i>	<i>tds</i> .copy_tds(<i>tds1</i> , <i>Vertex_handle</i> <i>v</i> = <i>Vertex_handle</i> ())	<i>tds1</i> is copied into <i>tds</i> . If <i>v</i> != <i>Vertex_handle</i> (), the vertex of <i>tds</i> corresponding to <i>v</i> is returned, otherwise <i>Vertex_handle</i> () is returned. <i>Precondition</i> : The optional argument <i>v</i> is a vertex of <i>tds1</i> .
<i>void</i>	<i>tds</i> .swap(& <i>tds1</i>)	Swaps <i>tds</i> and <i>tds1</i> . There is no copy of cells and vertices, thus this method runs in constant time. This method should be preferred to <i>tds</i> = <i>tds1</i> or <i>tds</i> (<i>tds1</i>) when <i>tds1</i> is deleted after that.
<i>void</i>	<i>tds</i> .clear()	Deletes all cells and vertices. <i>tds</i> is reset as a triangulation data structure constructed by the default constructor.

Operations

Access Functions

<i>int</i>	<i>tds</i> .dimension()	The dimension of the triangulated topological sphere.
<i>size_type</i>	<i>tds</i> .number_of_vertices()	The number of vertices. Note that the triangulation data structure has one more vertex than an associated geometric triangulation, if there is one, since the infinite vertex is a standard vertex and is thus also counted.
<i>size_type</i>	<i>tds</i> .number_of_cells()	The number of cells. Returns 0 if <i>tds</i> .dimension()< 3.

Non constant-time access functions

<i>size_type</i>	<i>tds</i> .number_of_facets()	The number of facets. Returns 0 if <i>tds</i> .dimension()< 2.
<i>size_type</i>	<i>tds</i> .number_of_edges()	The number of edges. Returns 0 if <i>tds</i> .dimension()< 1.

————— advanced —————

Setting

<i>void</i>	<i>tds</i> .set_dimension(<i>int</i> <i>n</i>)	Sets the dimension to <i>n</i> .
-------------	--	----------------------------------

————— advanced —————

Queries

<i>bool</i>	<i>tds</i> .is_vertex(<i>Vertex_handle</i> <i>v</i>)	Tests whether <i>v</i> is a vertex of <i>tds</i> .
<i>bool</i>	<i>tds</i> .is_edge(<i>Cell_handle</i> <i>c</i> , <i>int</i> <i>i</i> , <i>int</i> <i>j</i>)	Tests whether (<i>c</i> , <i>i</i> , <i>j</i>) is an edge of <i>tds</i> . Answers <i>false</i> when <i>dimension</i> () < 1 . <i>Precondition</i> : <i>i</i> , <i>j</i> ∈ {0,1,2,3}

bool *tds.is_edge(Vertex_handle u, Vertex_handle v, Cell_handle & c, int & i, int & j)*

Tests whether (u,v) is an edge of *tds*. If the edge is found, it computes a cell *c* having this edge and the indices *i* and *j* of the vertices *u* and *v*, in this order.

bool *tds.is_edge(Vertex_handle u, Vertex_handle v)*

Tests whether (u,v) is an edge of *tds*.

bool *tds.is_facet(Cell_handle c, int i)*

Tests whether (c,i) is a facet of *tds*. Answers *false* when *dimension()* < 2 .

Precondition: $i \in \{0, 1, 2, 3\}$

bool *tds.is_facet(Vertex_handle u,
 Vertex_handle v,
 Vertex_handle w,
 Cell_handle & c,
 int & i,
 int & j,
 int & k)*

Tests whether (u,v,w) is a facet of *tds*. If the facet is found, it computes a cell *c* having this facet and the indices *i, j* and *k* of the vertices *u, v* and *w*, in this order.

bool *tds.is_cell(Cell_handle c)*

Tests whether *c* is a cell of *tds*. Answers *false* when *dimension()* < 3 .

bool *tds.is_cell(Vertex_handle u,
 Vertex_handle v,
 Vertex_handle w,
 Vertex_handle t,
 Cell_handle & c,
 int & i,
 int & j,
 int & k,
 int & l)*

Tests whether (u,v,w,t) is a cell of *tds*. If the cell *c* is found, it computes the indices *i, j, k* and *l* of the vertices *u, v, w* and *t* in *c*, in this order.

There is a method *has_vertex* in the cell class. The analogous methods for facets are defined here.

bool *tds.has_vertex(Facet f, Vertex_handle v, int & j)*

If *v* is a vertex of *f*, then *j* is the index of *v* in the cell *f.first*, and the method returns *true*.

Precondition: tds.dimension()==3

bool *tds.has_vertex(Cell_handle c, int i, Vertex_handle v, int & j)*

Same for facet (c,i) . Computes the index *j* of *v* in *c*.

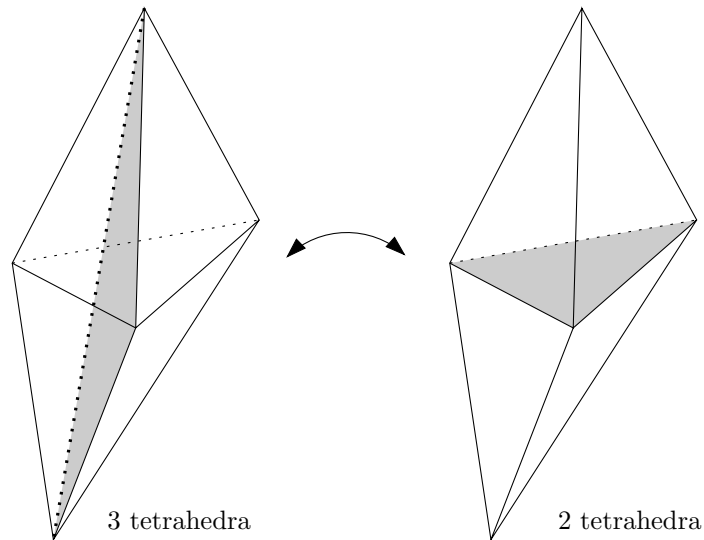

Figure 38.7: Flips.

```
bool    tds.has_vertex( Facet f, Vertex_handle v)
bool    tds.has_vertex( Cell_handle c, int i, Vertex_handle v)
```

Same as the first two methods, but these two methods do not return the index of the vertex.

The following three methods test whether two facets have the same vertices.

```
bool    tds.are_equal( Facet f, Facet g)
bool    tds.are_equal( Cell_handle c, int i, Cell_handle n, int j)
bool    tds.are_equal( Facet f, Cell_handle n, int j)
```

For these three methods:
Precondition: `tds.dimension()==3`.

Flips

Two kinds of flips exist for a three-dimensional triangulation. They are reciprocal. To be flipped, an edge must be incident to three tetrahedra. During the flip, these three tetrahedra disappear and two tetrahedra appear. Figure 38.7(left) shows the edge that is flipped as bold dashed, and one of its three incident facets is shaded. On the right, the facet shared by the two new tetrahedra is shaded.

The following methods guarantee the validity of the resulting 3D combinatorial triangulation. Moreover the flip operations do not invalidate the vertex handles, and only invalidate the cell handles of the affected cells.

Flips for a 2d triangulation are not implemented yet

```
bool    tds.flip( Edge e)
bool    tds.flip( Cell_handle c, int i, int j)
```

Before flipping, these methods check that edge $e=(c,i,j)$ is flip-pable (which is quite expensive). They return *false* or *true* according to this test.

<i>void</i>	<i>tds.flip_flippable(Edge e)</i>	
<i>void</i>	<i>tds.flip_flippable(Cell_handle c, int i, int j)</i>	Should be preferred to the previous methods when the edge is known to be flippable. <i>Precondition:</i> The edge is flippable.
<i>bool</i>	<i>tds.flip(Facet f)</i>	
<i>bool</i>	<i>tds.flip(Cell_handle c, int i)</i>	Before flipping, these methods check that facet $f=(c,i)$ is flippable (which is quite expensive). They return <i>false</i> or <i>true</i> according to this test.
<i>void</i>	<i>tds.flip_flippable(Facet f)</i>	
<i>void</i>	<i>tds.flip_flippable(Cell_handle c, int i)</i>	Should be preferred to the previous methods when the facet is known to be flippable. <i>Precondition:</i> The facet is flippable.

Insertions

The following modifier member functions guarantee the combinatorial validity of the resulting triangulation.

<i>Vertex_handle</i>	<i>tds.insert_in_cell(Cell_handle c)</i>	Creates a new vertex, inserts it in cell c and returns its handle. The cell c is split into four new cells, each of these cells being formed by the new vertex and a facet of c . <i>Precondition:</i> $tds.dimension() = 3$ and c is a cell of tds .
<i>Vertex_handle</i>	<i>tds.insert_in_facet(Facet f)</i>	Creates a new vertex, inserts it in facet f and returns its handle. In dimension 3, the two incident cells are split into 3 new cells; in dimension 2, the facet is split into 3 facets. <i>Precondition:</i> $tds.dimension() \geq 2$ and f is a facet of tds .
<i>Vertex_handle</i>	<i>tds.insert_in_facet(Cell_handle c, int i)</i>	Creates a new vertex, inserts it in facet i of c and returns its handle. <i>Precondition:</i> $tds.dimension() \geq 2$, $i \in \{0,1,2,3\}$ in dimension 3, $i = 3$ in dimension 2 and (c,i) is a facet of tds .
<i>Vertex_handle</i>	<i>tds.insert_in_edge(Edge e)</i>	Creates a new vertex, inserts it in edge e and returns its handle. In dimension 3, all the incident cells are split into 2 new cells; in dimension 2, the 2 incident facets are split into 2 new facets; in dimension 1, the edge is split into 2 new edges. <i>Precondition:</i> $tds.dimension() \geq 1$ and e is an edge of tds .

Vertex_handle *tds.insert_in_edge(Cell_handle c, int i, int j)*

Creates a new vertex, inserts it in edge (i, j) of c and returns its handle.

Precondition: $tds.dimension() \geq 1$. $i \neq j$, $i, j \in \{0, 1, 2, 3\}$ in dimension 3, $i, j \in \{0, 1, 2\}$ in dimension 2, $i, j \in \{0, 1\}$ in dimension 1 and (c, i, j) is an edge of tds .

Vertex_handle *tds.insert_increase_dimension(Vertex_handle star = Vertex_handle())*

Transforms a triangulation of the sphere S^d of \mathbb{R}^{d+1} into the triangulation of the sphere S^{d+1} of \mathbb{R}^{d+2} by adding a new vertex v : v is linked to all the vertices to triangulate one of the two half-spheres of dimension $(d+1)$. Vertex $star$ is used to triangulate the second half-sphere (when there is an associated geometric triangulation, $star$ is in fact the vertex associated with its infinite vertex). See Figure 38.8.

The numbering of the cells is such that, if f was a face of maximal dimension in the initial triangulation, then (f, v) (in this order) is the corresponding face in the new triangulation. This method can be used to insert the first two vertices in an empty triangulation.

A handle to v is returned.

Precondition: $tds.dimension() = d < 3$. When $tds.number_of_vertices() > 0$, $star \neq Vertex_handle()$ and $star$ is a vertex of tds .

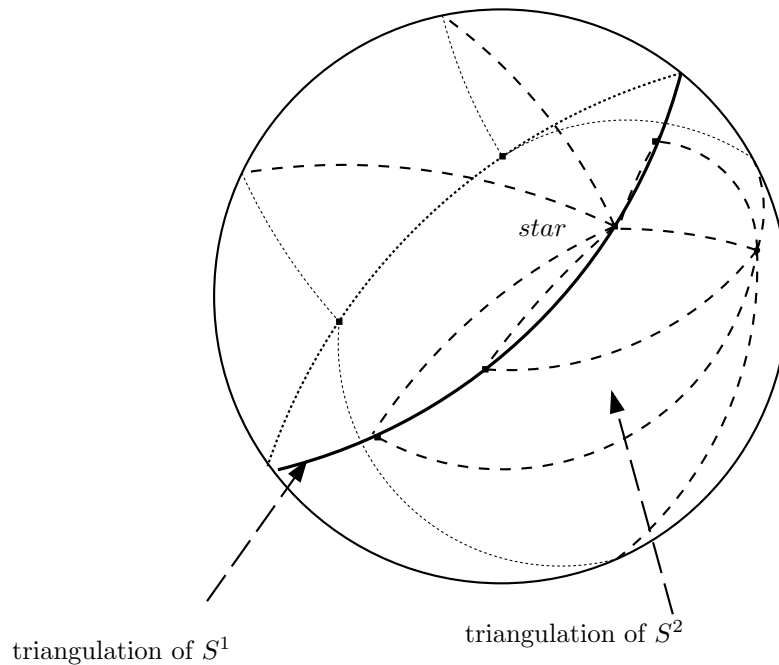

Figure 38.8: *insert_increase_dimension* (1-dimensional case).

template <class CellIt>

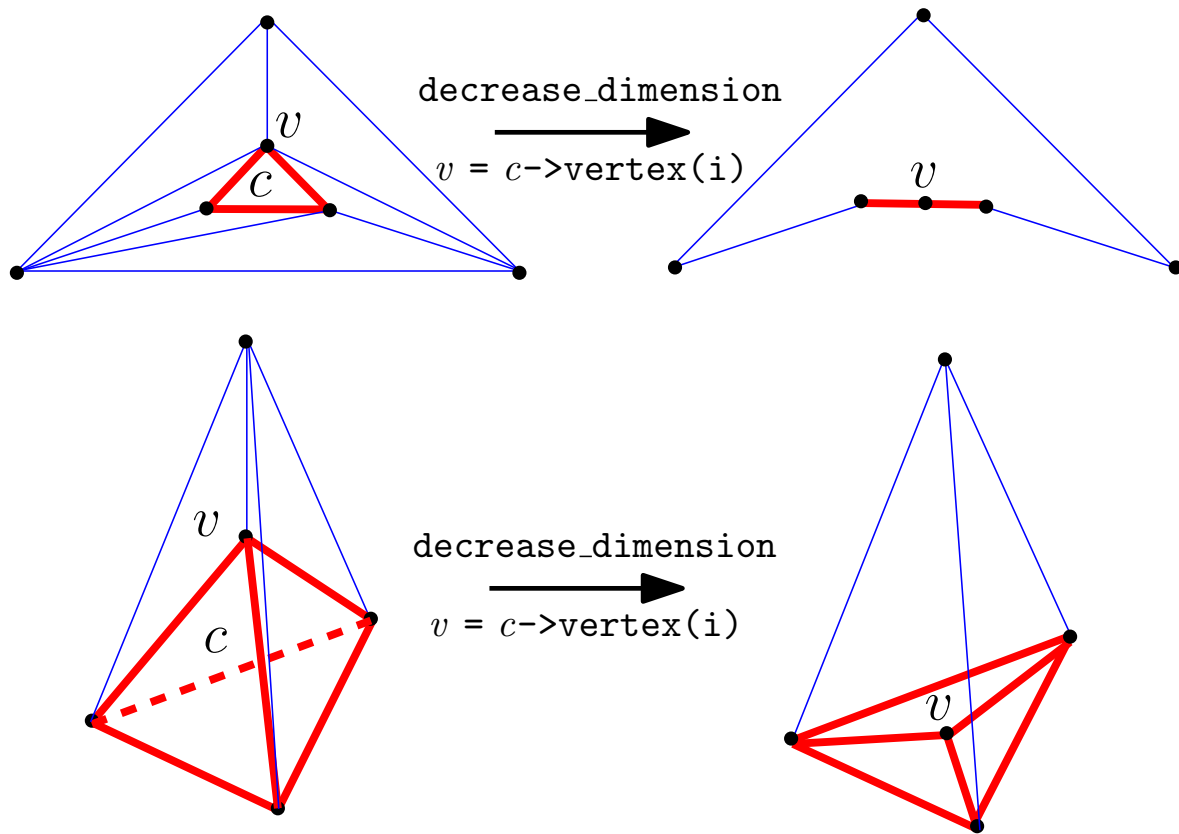

Figure 38.9: From an S^d data structure to an S^{d-1} data structure (top: $d == 2$, bottom: $d == 3$).

Dimension Manipulation

The following operation, `decrease_dimension`, is necessary when the displacement of a vertex decreases the dimension of the triangulation.

```
void          tds.decrease_dimension( Cell_handle c, int i)
```

The link of a vertex v is formed by the facets disjoint from v that are included in the cells incident to v . When the link of $v = c \rightarrow \text{vertex}(i)$ contains all the other vertices, `decrease_dimension` crushes the triangulation of the sphere S^d of \mathbb{R}^{d+1} onto the triangulation of the sphere S^{d-1} of \mathbb{R}^d formed by the link of v augmented with the vertex v itself, for $d=2,3$; this one is placed on the facet (c, i) (see Fig. 38.9).

Precondition: The dimension must be 2 or 3. The degree of v must be equal to the total number of vertices of the triangulation data structure minus 1.

— advanced —

Other modifiers

The following modifiers can affect the validity of the triangulation data structure.

<i>void</i>	<i>tds.reorient()</i>	Changes the orientation of all cells of the triangulation data structure. <i>Precondition:</i> <i>tds.dimension()</i> ≥ 1 .
<i>Vertex_handle</i>	<i>tds.create_vertex(Vertex v = Vertex())</i>	Adds a copy of the vertex <i>v</i> to the triangulation data structure.
<i>Vertex_handle</i>	<i>tds.create_vertex(Vertex_handle v)</i>	Creates a vertex which is a copy of the one pointed to by <i>v</i> and adds it to the triangulation data structure.
<i>Cell_handle</i>	<i>tds.create_cell(Cell c = Cell())</i>	Adds a copy of the cell <i>c</i> to the triangulation data structure.
<i>Cell_handle</i>	<i>tds.create_cell(Cell_handle c)</i>	Creates a cell which is a copy of the one pointed to by <i>c</i> and adds it to the triangulation data structure.
<i>Cell_handle</i>	<i>tds.create_cell(Vertex_handle v0, Vertex_handle v1, Vertex_handle v2, Vertex_handle v3)</i>	Creates a cell and adds it into the triangulation data structure. Initializes the vertices of the cell, its neighbor handles being initialized with the default constructed handle.
<i>Cell_handle</i>	<i>tds.create_cell(Vertex_handle v0, Vertex_handle v1, Vertex_handle v2, Vertex_handle v3, Cell_handle n0, Cell_handle n1, Cell_handle n2, Cell_handle n3)</i>	Creates a cell, initializes its vertices and neighbors, and adds it into the triangulation data structure.
<i>void</i>	<i>tds.delete_vertex(Vertex_handle v)</i>	Removes the vertex from the triangulation data structure. <i>Precondition:</i> The vertex is a vertex of <i>tds</i> .
<i>void</i>	<i>tds.delete_cell(Cell_handle c)</i>	Removes the cell from the triangulation data structure. <i>Precondition:</i> The cell is a cell of <i>tds</i> .

```
template <class VertexIt>
void          tds.delete_vertices( VertexIt first, VertexIt last)
```

Calls *delete_vertex* over an iterator range of value type *Vertex_handle*.

```
template <class CellIt>
void          tds.delete_cells( CellIt first, CellIt last)
```

Calls *delete_cell* over an iterator range of value type *Cell_handle*.

└────────── *advanced* ─────────┘

Traversing the triangulation

```
Cell_iterator  tds.cells_begin()      Returns cells_end() when tds.dimension() < 3.
Cell_iterator  tds.cells_end()
Cell_iterator  tds.raw_cells_begin()
```

Low-level access to the cells, does not return *cells_end()* when *tds.dimension()* < 3.

```
Cell_iterator  tds.raw_cells_end()
Facet_iterator tds.facets_begin()     Returns facets_end() when tds.dimension() < 2.
Facet_iterator tds.facets_end()
Edge_iterator  tds.edges_begin()     Returns edges_end() when tds.dimension() < 1.
Edge_iterator  tds.edges_end()
Vertex_iterator tds.vertices_begin()
Vertex_iterator tds.vertices_end()
```

Cell and facet circulators

```
Cell_circulator tds.incident_cells( Edge e)           Starts at an arbitrary cell incident to e.
                                                         Precondition: tds.dimension() = 3
Cell_circulator tds.incident_cells( Cell_handle c, int i, int j) As above for edge (i,j) of c.
Cell_circulator tds.incident_cells( Edge e, Cell_handle start) Starts at cell start.
                                                         Precondition: tds.dimension() = 3 and
                                                         start is incident to e.
Cell_circulator tds.incident_cells( Cell_handle c, int i, int j, Cell_handle start)
                                                         As above for edge (i,j) of c.
```

The following circulators on facets are defined only in dimension 3, though facets are defined also in dimension 2: there are only two facets sharing an edge in dimension 2.

```
Facet_circulator tds.incident_facets( Edge e)         Starts at an arbitrary facet incident to e.
                                                         Precondition: tds.dimension() = 3
Facet_circulator tds.incident_facets( Cell_handle c, int i, int j) As above for edge (i,j) of c.
Facet_circulator tds.incident_facets( Edge e, Facet start) Starts at facet start.
                                                         Precondition: start is incident to e.
Facet_circulator tds.incident_facets( Edge e, Cell_handle start, int f)
                                                         Starts at facet of index f in start.
```

Facet_circulator *tds.incident_facets(Cell_handle c, int i, int j, Facet start)*

As above for edge (i,j) of c .

Facet_circulator *tds.incident_facets(Cell_handle c, int i, int j, Cell_handle start, int f)*

As above for edge (i,j) of c and facet $(start,f)$.

Traversal of the incident cells, facets and edges, and the adjacent vertices of a given vertex

template <class OutputIterator>

OutputIterator *tds.incident_cells(Vertex_handle v, OutputIterator cells)*

Copies the *Cell_handles* of all cells incident to v to the output iterator *cells*. Returns the resulting output iterator.

Precondition: *tds.dimension()* = 3, $v \neq \text{Vertex_handle}()$, *tds.is_vertex(v)*.

template <class OutputIterator>

OutputIterator *tds.incident_facets(Vertex_handle v, OutputIterator facets)*

Copies the *Facets* incident to v to the output iterator *facets*. Returns the resulting output iterator.

Precondition: *tds.dimension()* > 1, $v \neq \text{Vertex_handle}()$, *tds.is_vertex(v)*.

template <class OutputIterator>

OutputIterator *tds.incident_edges(Vertex_handle v, OutputIterator edges)*

Copies all *Edges* incident to v to the output iterator *edges*. Returns the resulting output iterator.

Precondition: *tds.dimension()* > 0, $v \neq \text{Vertex_handle}()$, *tds.is_vertex(v)*.

template <class OutputIterator>

OutputIterator *tds.adjacent_vertices(Vertex_handle v, OutputIterator vertices)*

Copies the *Vertex_handles* of all vertices adjacent to v to the output iterator *vertices*. If *tds.dimension()* < 0, then do nothing. Returns the resulting output iterator.

Precondition: $v \neq \text{Vertex_handle}()$, *tds.is_vertex(v)*.

size_type *tds.degree(Vertex_handle v)*

Returns the degree of a vertex, that is, the number of incident vertices.

Precondition: $v \neq \text{Vertex_handle}()$, *tds.is_vertex(v)*.

Traversal between adjacent cells

<i>int</i>	<i>tds.mirror_index(Cell_handle c, int i)</i>	Returns the index of <i>c</i> in its i^{th} neighbor. <i>Precondition:</i> $i \in \{0, 1, 2, 3\}$.
<i>Vertex_handle</i>	<i>tds.mirror_vertex(Cell_handle c, int i)</i>	Returns the vertex of the i^{th} neighbor of <i>c</i> that is opposite to <i>c</i> . <i>Precondition:</i> $i \in \{0, 1, 2, 3\}$.
<i>Facet</i>	<i>tds.mirror_facet(Facet f)</i>	Returns the same facet viewed from the other adjacent cell.

debugging support

Checking

<i>bool</i>	<i>tds.is_valid(bool verbose = false)</i>	Checks the combinatorial validity of the triangulation by checking the local validity of all its cells and vertices (see functions below). (See Section 38.1.) Moreover, the Euler relation is tested. When <i>verbose</i> is set to <i>true</i> , messages are printed to give a precise indication on the kind of invalidity encountered.
<i>bool</i>	<i>tds.is_valid(Vertex_handle v, bool verbose = false)</i>	Checks the local validity of the adjacency relations of the triangulation. It also calls the <i>is_valid</i> member function of the vertex. When <i>verbose</i> is set to <i>true</i> , messages are printed to give a precise indication on the kind of invalidity encountered.
<i>bool</i>	<i>tds.is_valid(Cell_handle c, bool verbose = false)</i>	Checks the local validity of the adjacency relations of the triangulation. It also calls the <i>is_valid</i> member function of the cell. When <i>verbose</i> is set to <i>true</i> , messages are printed to give a precise indication on the kind of invalidity encountered.

debugging support

I/O

<i>istream&</i>	<i>istream& is >> & tds</i>	Reads a combinatorial triangulation from <i>is</i> and assigns it to <i>tds</i>
<i>ostream&</i>	<i>ostream& os << tds</i>	Writes <i>tds</i> into the stream <i>os</i>

The information stored in the *iostream* is: the dimension, the number of vertices, the number of cells, the indices of the vertices of each cell, then the indices of the neighbors of each cell, where the index corresponds to the preceding list of cells. When dimension < 3 , the same information is stored for faces of maximal dimension instead of cells.

Has Models

CGAL::Triangulation_data_structure_3

See Also

TriangulationDataStructure_3::Vertex

TriangulationDataStructure_3::Cell

TriangulationDataStructure_3::Cell

Definition

The concept Cell stores four *Vertex_handles* to its four vertices and four *Cell_handles* to its four neighbors. The vertices are indexed 0, 1, 2, and 3 in consistent order. The neighbor indexed i lies opposite to vertex i .

In degenerate dimensions, cells are used to store faces of maximal dimension: in dimension 2, each cell represents only one facet of index 3, and 3 edges (0,1), (1,2) and (2,0); in dimension 1, each cell represents one edge (0,1). (See also Section [38.1](#).)

Types

The class Cell defines the following types.

```
typedef TriangulationDataStructure_3      Triangulation_data_structure;
typedef TriangulationDataStructure_3::Vertex_handle  Vertex_handle;
typedef TriangulationDataStructure_3::Cell_handle   Cell_handle;
```

Creation

In order to obtain new cells or destruct unused cells, the user must call the *create_cell()* and *delete_cell()* methods of the triangulation data structure.

Operations

Access Functions

<i>Vertex_handle</i>	<i>c.vertex(int i)</i>	Returns the vertex i of c . <i>Precondition:</i> $i \in \{0, 1, 2, 3\}$.
<i>int</i>	<i>c.index(Vertex_handle v)</i>	Returns the index of vertex v in c . <i>Precondition:</i> v is a vertex of c .
<i>bool</i>	<i>c.has_vertex(Vertex_handle v)</i>	Returns <i>true</i> if v is a vertex of c .
<i>bool</i>	<i>c.has_vertex(Vertex_handle v, int & i)</i>	Returns <i>true</i> if v is a vertex of c , and computes its index i in c .
<i>Cell_handle</i>	<i>c.neighbor(int i)</i>	Returns the neighbor i of c . <i>Precondition:</i> $i \in \{0, 1, 2, 3\}$.
<i>int</i>	<i>c.index(Cell_handle n)</i>	Returns the index corresponding to neighboring cell n . <i>Precondition:</i> n is a neighbor of c .
<i>bool</i>	<i>c.has_neighbor(Cell_handle n)</i>	Returns <i>true</i> if n is a neighbor of c .
<i>bool</i>	<i>c.has_neighbor(Cell_handle n, int & i)</i>	Returns <i>true</i> if n is a neighbor of c , and computes its index i in c .

Setting

<i>void</i>	<i>c.set_vertex(int i, Vertex_handle v)</i>	Sets vertex <i>i</i> to <i>v</i> . <i>Precondition:</i> $i \in \{0, 1, 2, 3\}$.
<i>void</i>	<i>c.set_vertices(Vertex_handle v0, Vertex_handle v1, Vertex_handle v2, Vertex_handle v3)</i>	

Sets the vertex pointers.

<i>void</i>	<i>c.set_neighbor(int i, Cell_handle n)</i>	Sets neighbor <i>i</i> to <i>n</i> . Precondition: $i \in \{0, 1, 2, 3\}$.
<i>void</i>	<i>c.set_neighbors(Cell_handle n0, Cell_handle n1, Cell_handle n2, Cell_handle n3)</i>	

Sets the neighbors pointers.

— *debugging support* —

Checking

```
bool c.is_valid( bool verbose = false, int level = 0)
```

User defined local validity checking function.

debugging support

TriangulationDataStructure_3::Vertex.

TriangulationDataStructure_3::Vertex

Definition

The concept Vertex represents the vertex class of a 3D-triangulation data structure. It must define the types and operations listed in this section. Some of these requirements are of geometric nature, they are *optional* when using the triangulation data structure class alone. They become compulsory when the triangulation data structure is used as a layer for the geometric triangulation class. (See Section 38.2.)

Types

Vertex:: Point *Optional for the triangulation data structure alone.*

The class Vertex defines types that are the same as some of the types defined by the triangulation data structure class *TriangulationDataStructure_3*.

```
typedef TriangulationDataStructure_3      Triangulation_data_structure;
typedef TriangulationDataStructure_3::Vertex_handle  Vertex_handle;
typedef TriangulationDataStructure_3::Cell_handle    Cell_handle;
```

Creation

In order to obtain new vertices or destruct unused vertices, the user must call the *create_vertex()* and *delete_vertex()* methods of the triangulation data structure.

Operations

Access Functions

<i>Cell_handle</i>	<i>v.cell()</i>	Returns a cell of the triangulation having <i>v</i> as vertex.
<i>Point</i>	<i>v.point()</i>	Returns the point stored in the vertex. <i>Optional for the triangulation data structure alone.</i>

Setting

<i>void</i>	<i>v.set_cell(Cell_handle c)</i>	Sets the incident cell to <i>c</i> .
<i>void</i>	<i>v.set_point(Point p)</i>	Sets the point to <i>p</i> . <i>Optional for the triangulation data structure alone.</i>

debugging support

Checking

bool *v.is_valid(bool verbose = false)*

Checks the validity of the vertex. Must check that its incident cell has this vertex. The validity of the base vertex is also checked.

When *verbose* is set to *true*, messages are printed to give a precise indication on the kind of invalidity encountered.

TriangulationDataStructure_3::Cell.

TriangulationDSCellBase_3

Definition

At the base level (see Sections 37.4 and 38.2), a cell stores handles to its four vertices and to its four neighbor cells. The vertices and neighbors are indexed 0, 1, 2 and 3. Neighbor i lies opposite to vertex i .

Since the Triangulation data structure is the class which defines the handle types, the cell base class has to be somehow parameterized by the Triangulation data structure. But since it is itself parameterized by the cell and vertex base classes, there is a cycle in the definition of these classes. In order to break the cycle, the base classes for vertex and cell which are given as arguments for the Triangulation data structure use *void* as Triangulation data structure parameter, and the Triangulation data structure then uses a *rebind*-like mechanism (similar to the one specified in *std::allocator*) in order to put itself as parameter to the vertex and cell classes. The *rebound* base classes so obtained are the classes which are used as base classes for the final vertex and cell classes. More information can be found in Section 38.2.

Types

The concept TriangulationDSCellBase_3 has to provide the following types.

TriangulationDSCellBase_3::template <typename TDS2> struct Rebind_TDS

This nested template class has to define a type *Other* which is the *rebound* cell, that is, the one whose *Triangulation_data_structure* will be the actually used one. The *Other* type will be the real base class of *Triangulation_data_structure_3::Cell*.

<i>typedef TriangulationDataStructure_3</i>	<i>Triangulation_data_structure;</i>
<i>typedef TriangulationDataStructure_3::Vertex_handle</i>	<i>Vertex_handle;</i>
<i>typedef TriangulationDataStructure_3::Cell_handle</i>	<i>Cell_handle;</i>
<i>typedef TriangulationDataStructure_3::Cell_data</i>	<i>TDS_data;</i>

Creation

<i>TriangulationDSCellBase_3 c;</i>	Default constructor
<i>TriangulationDSCellBase_3 c(Vertex_handle v0, Vertex_handle v1, Vertex_handle v2, Vertex_handle v3);</i>	

Initializes the vertices with $v0$, $v1$, $v2$, $v3$. Neighbors are initialized to the default constructed handle.

*TriangulationDSCellBase_3 c(Vertex_handle v0,
Vertex_handle v1,
Vertex_handle v2,
Vertex_handle v3,
Cell_handle n0,
Cell_handle n1,
Cell_handle n2,*

Cell_handle n3)

Initializes the vertices with $v0$, $v1$, $v2$, $v3$ and the neighbors with $n0$, $n1$, $n2$, $n3$.

Access Functions

<i>Vertex_handle</i>	<i>c.vertex(int i)</i>	Returns the vertex i of c . <i>Precondition:</i> $i \in \{0, 1, 2, 3\}$.
<i>int</i>	<i>c.index(Vertex_handle v)</i>	Returns the index of v . <i>Precondition:</i> v is a vertex of c
<i>bool</i>	<i>c.has_vertex(Vertex_handle v)</i>	True iff v is a vertex of c .
<i>bool</i>	<i>c.has_vertex(Vertex_handle v, int & i)</i>	Returns <i>true</i> if v is a vertex of c , and computes its index i in c .
<i>Cell_handle</i>	<i>c.neighbor(int i)</i>	Returns the neighbor i of c . <i>Precondition:</i> $i \in \{0, 1, 2, 3\}$.
<i>int</i>	<i>c.index(Cell_handle n)</i>	Returns the index of cell n in c . <i>Precondition:</i> n is a neighbor of c .
<i>bool</i>	<i>c.has_neighbor(Cell_handle n)</i>	Returns <i>true</i> if n is a neighbor of c .
<i>bool</i>	<i>c.has_neighbor(Cell_handle n, int & i)</i>	Returns <i>true</i> if n is a neighbor of c , and computes its index i in c .

Setting

<i>void</i>	<i>c.set_vertex(int i, Vertex_handle v)</i>	Sets vertex i to v . <i>Precondition:</i> $i \in \{0, 1, 2, 3\}$.
<i>void</i>	<i>c.set_vertices()</i>	Sets the vertices to the default constructed handle.
<i>void</i>	<i>c.set_vertices(Vertex_handle v0, Vertex_handle v1, Vertex_handle v2, Vertex_handle v3)</i>	Sets the vertices.
<i>void</i>	<i>c.set_neighbor(int i, Cell_handle n)</i>	Sets neighbor i to n . <i>Precondition:</i> $i \in \{0, 1, 2, 3\}$.
<i>void</i>	<i>c.set_neighbors()</i>	Sets the neighbors to the default constructed handle.
<i>void</i>	<i>c.set_neighbors(Cell_handle n0, Cell_handle n1, Cell_handle n2, Cell_handle n3)</i>	Sets the neighbors.

— debugging support —

Checking

bool *c.is_valid(bool verbose = false, int level = 0)*

Performs any desired geometric test on a cell.
When *verbose* is set to *true*, messages are printed to give a precise indication of the kind of invalidity encountered. *level* increases the level of testing.

TriangulationDSVertexBase_3

Definition

At the bottom level of 3D-triangulations (see Sections 37.4 and 38.2), a vertex provides access to one of its incident cells through a handle.

Note that when you use the triangulation data structure as parameter of a geometric triangulation, the vertex base class has additional geometric requirements : it has to match the *TriangulationVertexBase_3* concept.

Since the Triangulation data structure is the class which defines the handle types, the vertex base class has to be somehow parameterized by the Triangulation data structure. But since it is itself parameterized by the cell and vertex base classes, there is a cycle in the definition of these classes. In order to break the cycle, the base classes for vertex and cell which are given as arguments for the Triangulation data structure use *void* as Triangulation data structure parameter, and the Triangulation data structure then uses a *rebind*-like mechanism (similar to the one specified in *std::allocator*) in order to put itself as parameter to the vertex and cell classes. The *rebound* base classes so obtained are the classes which are used as base classes for the final vertex and cell classes. More information can be found in Section 38.2.

Types

The class *TriangulationDSVertexBase_3* has to define the following types.

TriangulationDSVertexBase_3::template <typename TDS2> struct Rebind_TDS

This nested template class has to define a type *Other* which is the *rebound* vertex, that is, the one whose *Triangulation_data_structure* will be the actually used one. The *Other* type will be the real base class of *Triangulation_data_structure_3::Vertex*.

<i>typedef TriangulationDataStructure_3</i>	<i>Triangulation_data_structure;</i>
<i>typedef TriangulationDataStructure_3::Vertex_handle</i>	<i>Vertex_handle;</i>
<i>typedef TriangulationDataStructure_3::Cell_handle</i>	<i>Cell_handle;</i>

Creation

<i>TriangulationDSVertexBase_3 v;</i>	Default constructor.
<i>TriangulationDSVertexBase_3 v(Cell_handle c);</i>	Constructs a vertex pointing to cell <i>c</i> .

Operations

Access Functions

CGAL::Triangulation_data_structure_3<TriangulationDSVertexBase_3, TriangulationDSCellBase_3>

Definition

The class *Triangulation_data_structure_3* stores a 3D-triangulation data structure and provides the optional geometric functionalities to be used as a parameter for a 3D-geometric triangulation (see Chapter 37).

The vertices and cells are stored in two nested containers, which are implemented using *CGAL::Compact_container*. The class may offer some flexibility for the choice of container in the future, in the form of additional template parameters.

```
#include <CGAL/Triangulation_data_structure_3.h>
```

Parameters

It is parameterized by base classes for vertices and cells which have to match the requirements for the concepts *TriangulationDSCellBase_3* and *TriangulationDSVertexBase_3* respectively (see page 2561 and page 2564).

They have the default values *Triangulation_ds_vertex_base_3<>* and *Triangulation_ds_cell_base_3<>* respectively.

Definition

The class *Triangulation_utils_3* defines operations on the indices of vertices and neighbors within a cell.

```
#include <CGAL/Triangulation_utils_3.h>
```

Operations

```
unsigned int    next_around_edge( unsigned int i, unsigned int j)
```

In dimension 3, index of the neighbor n that is next to the current cell, when turning positively around an oriented edge whose endpoints are indexed i and j . According to the usual numbering of vertices and neighbors in a given cell, it is also the index of the vertex opposite to this neighbor n . (see Figure 38.10).

Precondition: $(i < 4) \ \&\& \ (j < 4) \ \&\& \ (i \neq j)$.

```
unsigned int    ccw( unsigned int i)
```

Has a meaning only in dimension 2.

Computes the index of the vertex that is next to the vertex numbered i in counterclockwise direction. (see Figure 38.10).

Precondition: $i < 3$.

```
unsigned int    cw( unsigned int i)
```

Same for clockwise.

The periodic 3D-triangulation class of CGAL is designed to represent the triangulations of a set of points in the three-dimensional flat torus. The triangulation forms a partition of the space it is computed in. It is a simplicial complex, i.e. it contains all incident j -simplices ($j < k$) of any k -simplex and two k -simplices either do not intersect or share a common j -face, $j < k$. The occurring simplices of dimension up to three are called *vertex*, *edge*, *facet*, and *cell*, respectively.

39.1 The Flat Torus

The 3D Periodic Triangulation package computes triangulations in the space \mathbb{T}_c^3 , which is defined as follows: Let $c \in \mathbb{R} \setminus \{0\}$ and G be the group $(c \cdot \mathbb{Z}^3, +)$, where $c \cdot \mathbb{Z}$ denotes the set containing all integer multiples of c . The flat torus is the quotient space: $\mathbb{T}_c^3 := \mathbb{R}^3 / G$. The parameter c defines the period.

The elements of \mathbb{T}_c^3 are the equivalence classes of sets of points in \mathbb{R}^3 . We call these points *representatives* of an element of \mathbb{T}_c^3 . The implementation works not directly on elements of \mathbb{T}_c^3 but on some representatives in \mathbb{R}^3 . So there need to be distinguished representatives to work on. Given α , β , and γ , the cube $[\alpha, \alpha + c) \times [\beta, \beta + c) \times [\gamma, \gamma + c)$ contains exactly one representative of each element in \mathbb{T}_c^3 . We call it *original domain*. From now on, when we talk about *points*, we generally mean representatives of elements of \mathbb{T}_c^3 that lie inside the original domain. Note that any input point is required to be an element of the half-open cube representing the original domain as defined above.

There are simplices containing points inside the original domain but also points outside it. The points outside the original domain are periodic copies of points inside the original domain. So, to specify a simplex we need points together with some additional information that determines the respective periodic copy of each point. The set of representatives of an element of \mathbb{T}_c^3 is a cubic point grid. We address each representative by a three-dimensional integer vector (o_x, o_y, o_z) , called *offset*. It represents the number of periods a representative in the original domain must be translated in x -, y -, and z -direction. The vector $(0, 0, 0)$ corresponds to the representative in the original domain. To specify a k -simplex we need $k + 1$ point-offset pairs (cf. Fig. 39.1).

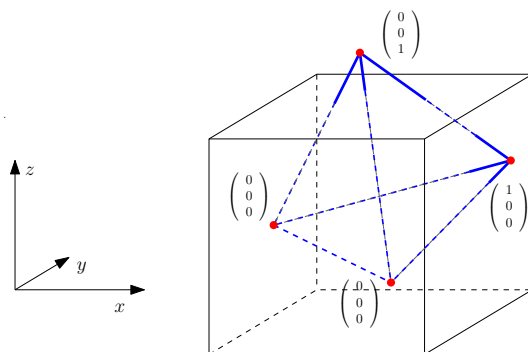

Figure 39.1: Offsets in a cell.

39.2 Representation

A triangulation is a collection of vertices and cells that are linked together through incidence and adjacency relations. Each cell gives access to its four incident vertices, their corresponding offsets, and to its four adjacent cells. Each vertex gives access to one of its incident cells.

The four vertices of a cell are indexed with 0, 1, 2 and 3 in positive orientation. The orientation of a simplex in

\mathbb{T}_c^3 is defined as the orientation of the corresponding simplex in \mathbb{R}^3 given by representatives determined by the respective offsets (see Figure 39.2).

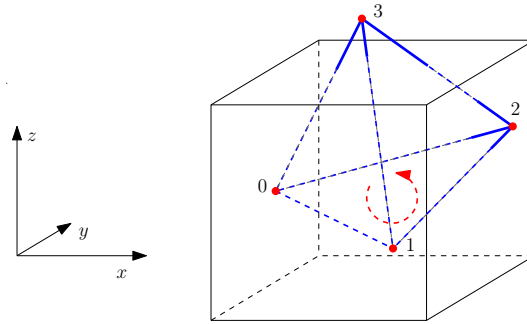

Figure 39.2: Orientation of a cell.

As in the underlying combinatorial triangulation (see Chapter 38), the neighbors of a cell are indexed with 0, 1, 2, 3 in such a way that the neighbor indexed by i is opposite to the vertex with the same index. Also edges (1-faces) and facets (2-faces) are not explicitly represented: a facet is given by a cell and an index (the facet i of a cell c is the facet of c that is opposite to the vertex with index i) and an edge is given by a cell and two indices (the edge (i, j) of a cell c is the edge whose endpoints are the vertices of c with indices i and j). See Figure 38.1.

Some point sets do not admit a triangulation in \mathbb{T}_c^3 . In this case we use 27 periodic copies of the point set arranged in a cube of edge length $3c$. Any point set constructed in this way has a triangulation in \mathbb{R}^3/G' with $G' = (3c \cdot \mathbb{Z}, +)$ [CT09]. So we compute the triangulation in this space, which is a *27-sheeted covering space* of \mathbb{T}_c^3 (see Figure 39.3).

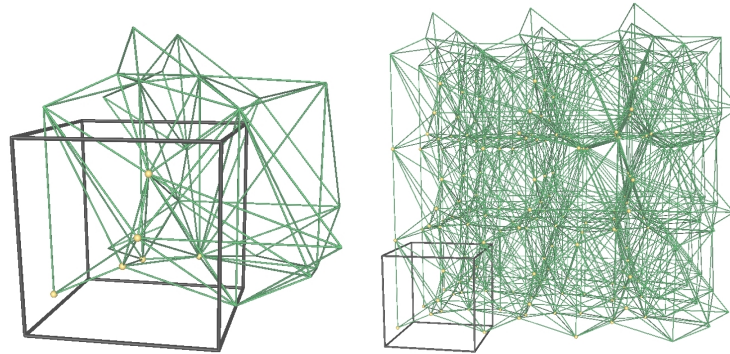

Figure 39.3: The same periodic triangulation in the 1-sheeted covering space and the 27-sheeted covering space.

The machinery that manages the copies is largely hidden from the user. However there are some effects that cannot be ignored. For example if the point set does not permit a triangulation in \mathbb{T}_c^3 then the combinatorial iterators (*Cell_iterator*, *Facet_iterator*, *Edge_iterator*, and *Vertex_iterator*) return all simplices that are internally stored, which correspond to 27 periodic copies of each geometric primitive (Tetrahedron, Triangle, Segment, and Point). This is necessary to ensure consistency in the adjacency relations. In case it is desired to have only one periodic copy of each primitive, we provide *geometric* iterators. They return geometric primitives of the triangulation without relations between them. Another effect is that when the algorithm switches from the 27-sheeted covering space to the 1-sheeted covering space, the *Vertex_handles* and *Cell_handles* referencing deleted items become invalid.

In the data structure each vertex stores the input point it corresponds to. If we are computing in the 27-sheeted

covering space, each vertex stores the representative *inside* the original domain it corresponds to. So, the 27 vertices corresponding to the same element of \mathbb{T}_c^3 all store the same representative in \mathbb{R}^3 , and not different periodic copies.

Validity A periodic triangulation is said to be *locally valid* iff

- (a)-(b) Its underlying combinatorial graph, the triangulation data structure, is *locally valid* (see Section 38.1 of Chapter 38)
- (c) Any cell has its vertices ordered according to positive orientation. See Figure 39.2.

39.3 Delaunay Triangulation

The class *Periodic_3_Delaunay_triangulation_3* implements Delaunay triangulations of point sets in \mathbb{T}_c^3 .

Delaunay triangulations have the *empty sphere property*, that is, the circumscribing sphere of each cell does not contain any other vertex of the triangulation in its interior. These triangulations are uniquely defined except in degenerate cases where five points are co-spherical. Note however that the CGAL implementation computes a unique triangulation even in these cases [DT03].

This implementation is fully dynamic: it supports both insertions of points and vertex removal.

39.4 Triangulation Hierarchy

The class *Periodic_3_triangulation_hierarchy_3* is the adaptation of the hierarchical structure described in chapter 37 to the periodic case.

39.5 Software Design

We have chosen the prefix “Periodic_3” to emphasize that the triangulation is periodic in all three directions of space. There are also “cylindrical” periodicities where the triangulation is periodic only in one or two directions of space.

The two main classes *Periodic_3_Delaunay_triangulation_3* and *Periodic_3_triangulation_3* provide high-level geometric functionality and are responsible for the geometric validity. *Periodic_3_Delaunay_triangulation_3* contains all the functionality that is special to Delaunay triangulations, such as point insertion and vertex removal, the side-of-sphere test, finding the conflicting region of a given point, dual functions etc. *Periodic_3_triangulation_3* contains all the functionality that is common to triangulations in general, such as location of a point in the triangulation [DPT02], access functions, geometric queries like the orientation test etc.

They are built as layers on top of a triangulation data structure, which stores their combinatorial structure. This separation between the geometry and the combinatorics is reflected in the software design by the fact that the triangulation classes take two template parameters:

- the **geometric traits** class, which provides the type of points to use as well as the elementary operations on them (predicates and constructions). Furthermore it contains the offset type. The concept for this parameter is described in more detail in Section 39.5.1 and as the concept *Periodic_3DelaunayTriangulationTraits_3* in the reference manual on page 2609.

- the **triangulation data structure** class, which stores the combinatorial structure, described in Section 39.5.2 and in more detail in Chapter 38. The triangulation data structure needs models of the concepts *Periodic_3TriangulationDSCellBase_3* and *Periodic_3TriangulationDSVertexBase_3* as template parameters.

39.5.1 The Geometric Traits Parameter

The first template parameter of the Delaunay triangulation class *Periodic_3DelaunayTriangulation_3*<*Periodic_3DelaunayTriangulationTraits_3*, *TriangulationDataStructure_3*> is the geometric traits class, described by the concept *Periodic_3DelaunayTriangulationTraits_3*. It is different to the *DelaunayTriangulationTraits_3* (see chapter 37.4.1) in that it implements all objects, predicates and constructions with using offsets.

The class *Periodic_3TriangulationTraits_3*<*Traits*, *Periodic_3Offset_3*> provides the required functionality. It expects two template parameters: A model of the concept *DelaunayTriangulationTraits_3* and a model of the concept *Periodic_3Offset_3*.

The kernels *Cartesian*, *Homogeneous*, *Simple_cartesian*, *Simple_homogeneous* and *Filtered_kernel* can all be used as models for *Traits*. *Periodic_3TriangulationTraits_3* provides exact predicates and exact constructions if *Traits* does. It provides exact predicates but not exact constructions if *Filtered_kernel*<*CK*> with *CK* an inexact kernel is used as its first template parameter. Using *Exact_predicates_inexact_constructions_kernel* (page ??) as *Traits* provides fast and exact predicates and not exact constructions, using *Exact_predicates_exact_constructions_kernel* (page ??) provides fast and exact predicates and exact constructions. The latter is recommended if the dual constructions and constructions of points, segments, triangles, and tetrahedra are used.

The second parameter *Periodic_3Offset_3* defaults to *Periodic_3_offset_3*.

39.5.2 The Triangulation Data Structure Parameter

The second template parameter of the main classes *Periodic_3Triangulation_3* and *Periodic_3DelaunayTriangulation_3* is a triangulation data structure class. This class can be seen as a container for the cells and vertices maintaining incidence and adjacency relations (see Chapter 38). A model of this triangulation data structure is *Triangulation_data_structure_3*, and it is described by the *TriangulationDataStructure_3* concept. This model is itself parameterized by a vertex base class and a cell base class, which gives the possibility to customize the vertices and cells used by the triangulation data structure, and hence by the geometric triangulation using it. To represent periodic triangulations the cell base and vertex base classes need to meet the concepts *Periodic_3TriangulationDSCellBase_3* and *Periodic_3TriangulationDSVertexBase_3*.

A default value for the triangulation data structure parameter is provided in all the triangulation classes, so it does not need to be specified by the user unless he wants to use a different triangulation data structure or a different vertex or cell base class.

39.5.3 Flexibility of the Design

Periodic_3Triangulation_3 uses the *TriangulationDataStructure_3* in essentially the same way as *Triangulation_3*. That is why the flexibility described in 37.4 is applicable in exactly the same way. Also the classes *Triangulation_vertex_base_with_info_3* and *Triangulation_cell_base_with_info_3* can be reused directly, see also Example 39.6.2.

39.6 Examples

39.6.1 Basic Example

This example shows the incremental construction of a 3D Delaunay triangulation, the location of a point and how to perform elementary operations on indices in a cell. It uses the default parameter of the *Periodic_3_Delaunay_triangulation_3* class for the triangulation data structure.

```
#include <CGAL/Exact_predicates_inexact_constructions_kernel.h>

39.6.2 Changing the Vertex Base

The following two examples show how the user can plug his own vertex base in a triangulation. Changing the cell base is similar.

Adding a Color

If the user does not need to add a type in a vertex that depends on the *TriangulationDataStructure_3* (e.g. a *Vertex_handle* or *Cell_handle*), then he can use the *Triangulation_vertex_base_with_info_3* class to add his own information easily in the vertices. The example below shows how to add a *CGAL::Color* this way.

```

#include <CGAL/Exact_predicates_inexact_constructions_kernel.h>
#include <CGAL/Periodic_3_triangulation_filtered_traits_3.h>
#include <CGAL/Periodic_3_Delaunay_triangulation_3.h>

```

```

#include <CGAL/Triangulation_vertex_base_with_info_3.h>
#include <CGAL/IO/Color.h>

typedef CGAL::Exact_predicates_inexact_constructions_kernel K;
typedef CGAL::Periodic_3_triangulation_filtered_traits_3<K> GT;

typedef CGAL::Periodic_3_triangulation_ds_vertex_base_3<> VbDS;
typedef CGAL::Triangulation_vertex_base_3<GT, VbDS> Vb;

typedef CGAL::Periodic_3_triangulation_ds_cell_base_3<> CbDS;
typedef CGAL::Triangulation_cell_base_3<GT, CbDS> Cb;

typedef CGAL::Triangulation_vertex_base_with_info_3<CGAL::Color, GT, Vb>
    VbInfo;
typedef CGAL::Triangulation_data_structure_3<VbInfo, Cb> TDS;
typedef CGAL::Periodic_3_Delaunay_triangulation_3<GT, TDS> PDT;

typedef PDT::Point Point;

int main()
{
    PDT T;

    T.insert(Point(0,0,0));
    T.insert(Point(.1,0,0));
    T.insert(Point(0,.1,0));
    T.insert(Point(0,0,.1));
    T.insert(Point(.2,.2,.2));
    T.insert(Point(.9,0,.1));

    // Set the color of finite vertices of degree 6 to red.
    PDT::Vertex_iterator vit;
    for (vit = T.vertices_begin(); vit != T.vertices_end(); ++vit)
        if (T.degree(vit) == 6)
            vit->info() = CGAL::RED;

    return 0;
}

```

File: examples/Periodic_3_triangulation_3/colored_vertices.cpp

Adding Handles

If the user needs to add a type in a vertex that depends on the *TriangulationDataStructure_3* (e.g. a *Vertex_handle* or *Cell_handle*), then he has to derive his own vertex base class, as the following example shows.

```

#include <CGAL/Exact_predicates_inexact_constructions_kernel.h>
#include <CGAL/Periodic_3_triangulation_filtered_traits_3.h>
#include <CGAL/Periodic_3_Delaunay_triangulation_3.h>
#include <CGAL/Periodic_3_triangulation_ds_vertex_base_3.h>
#include <CGAL/Triangulation_vertex_base_3.h>

```

```

template < class GT, class VbDS,
           class Vb = CGAL::Triangulation_vertex_base_3<GT,VbDS> >
class My_vertex_base
: public Vb
{
public:
    typedef typename Vb::Vertex_handle  Vertex_handle;
    typedef typename Vb::Cell_handle     Cell_handle;
    typedef typename Vb::Point           Point;

    template < class TDS2 >
    struct Rebind_TDS {
        typedef typename Vb::template Rebind_TDS<TDS2>::Other  Vb2;
        typedef My_vertex_base<GT, Vb2>                        Other;
    };

    My_vertex_base() {}

    My_vertex_base(const Point& p)
        : Vb(p) {}

    My_vertex_base(const Point& p, Cell_handle c)
        : Vb(p, c) {}

    Vertex_handle  vh;
    Cell_handle    ch;
};

typedef CGAL::Exact_predicates_inexact_constructions_kernel K;
typedef CGAL::Periodic_3_triangulation_filtered_traits_3<K> GT;

typedef CGAL::Periodic_3_triangulation_ds_vertex_base_3<> VbDS;
typedef CGAL::Periodic_3_triangulation_ds_cell_base_3<> CbDS;
typedef CGAL::Triangulation_cell_base_3<GT,CbDS> Cb;

typedef CGAL::Triangulation_data_structure_3<My_vertex_base<GT,VbDS>, Cb>
    TDS;
typedef CGAL::Periodic_3_Delaunay_triangulation_3<GT,TDS> PDT;

typedef PDT::Vertex_handle  Vertex_handle;
typedef PDT::Point          Point;

int main()
{
    PDT T;

    Vertex_handle v0 = T.insert(Point(0,0,0));
    Vertex_handle v1 = T.insert(Point(.1,0,0));
    Vertex_handle v2 = T.insert(Point(0,.1,0));
    Vertex_handle v3 = T.insert(Point(0,0,.1));
    Vertex_handle v4 = T.insert(Point(.2,.2,.2));
    Vertex_handle v5 = T.insert(Point(.9,0,.1));

```

```

    // Now we can link the vertices as we like.
    v0->vh = v1;
    v1->vh = v2;
    v2->vh = v3;
    v3->vh = v4;
    v4->vh = v5;
    v5->vh = v0;

    return 0;
}

```

File: examples/Periodic_3_triangulation_3/periodic_adding_handles.cpp

39.6.3 The 27-sheeted Covering Space

The user can check at any time whether a triangulation would be a simplicial complex in \mathbb{T}_c^3 and force a conversion if so. However this should be done very carefully in order to be sure that the internal structure always remains a simplicial complex and thus a triangulation.

In this example we construct a triangulation that can be converted to the 1-sheeted covering space. However, we can insert new points such that the point set does not have a Delaunay triangulation in the 1-sheeted covering space anymore, so the triangulation is not *extensible*.

```

#include <CGAL/Exact_predicates_inexact_constructions_kernel.h>
#include <CGAL/Periodic_3_triangulation_traits_3.h>
#include <CGAL/Periodic_3_Delaunay_triangulation_3.h>

#include <iostream>
#include <vector>

typedef CGAL::Exact_predicates_inexact_constructions_kernel K;
typedef CGAL::Periodic_3_triangulation_traits_3<K> GT;

typedef CGAL::Periodic_3_Delaunay_triangulation_3<GT> PDT;

typedef PDT::Point Point;
typedef PDT::Covering_sheets Covering_sheets;

int main()
{
    PDT T;

    // Input point grid (27 points)
    for (double x=0. ; x < .9 ; x += 0.33) {
        for (double y=0. ; y < .9 ; y += 0.33) {
            for (double z=0. ; z < .9 ; z += 0.33) {
                T.insert(Point(x,y,z));
            }
        }
    }

    Covering_sheets cs = T.number_of_sheets();
    std::cout<<"Current covering: "<<cs[0]<<' '<<cs[1]<<'
    '<<cs[2]<<std::endl;
}

```

```

if ( T.is_triangulation_in_1_sheet() ) {
    // = true
    bool is_extensible = T.is_extensible_triangulation_in_1_sheet_h1()
        || T.is_extensible_triangulation_in_1_sheet_h2();
    // = false
    T.convert_to_1_sheeted_covering();
    cs = T.number_of_sheets();
    std::cout<<"Current covering: "<<cs[0]<<' ' <<cs[1]<<'
'<<cs[2]<<std::endl;
    if ( is_extensible )
        // = false
        std::cout<<"It is safe to change the triangulation
here."<<std::endl;
    else
        std::cout<<"It is NOT safe to change the triangulation
here!"<<std::endl;

    T.convert_to_27_sheeted_covering();
    cs = T.number_of_sheets();
    std::cout<<"Current covering: "<<cs[0]<<' ' <<cs[1]<<'
'<<cs[2]<<std::endl;
}

std::cout<<"It is (again) safe to modify the
triangulation."<<std::endl;

return 0;
}

```

File: examples/Periodic_3_triangulation_3/covering.cpp

39.6.4 Large Point Set

For large point sets there are two optimizations available. Firstly, there is spatial sorting that sorts the input points according to a Hilbert curve, see chapter 63.2 on page ???. The second one inserts 36 appropriately chosen dummy points to avoid the use of a 27-sheeted covering space in the beginning. The 36 dummy points are deleted in the end. If the point set turns out to not have a Delaunay triangulation in the 1-sheeted covering space, the triangulation is converted to the 27-sheeted covering space during the removal of the 36 dummy points. This might take even longer than computing the triangulation without using this optimization. In general, uniformly distributed random point sets of more than 1000 points have a Delaunay triangulation in the 1-sheeted covering space.

It is recommended to run this example only when compiled in release mode because of the relatively large number of points.

```

#include <CGAL/Exact_predicates_inexact_constructions_kernel.h>
#include <CGAL/Periodic_3_triangulation_traits_3.h>
#include <CGAL/Periodic_3_Delaunay_triangulation_3.h>

#include <CGAL/Random.h>
#include <CGAL/point_generators_3.h>
#include <CGAL/Timer.h>

```

```

#include <iostream>
#include <vector>

typedef CGAL::Exact_predicates_inexact_constructions_kernel K;
typedef CGAL::Periodic_3_triangulation_traits_3<K> GT;

typedef CGAL::Periodic_3_Delaunay_triangulation_3<GT> PDT;

typedef PDT::Point          Point;

int main()
{
    CGAL::Timer t;
    typedef CGAL::Creator_uniform_3<double, Point> Creator;
    CGAL::Random random(7);
    CGAL::Random_points_in_cube_3<Point, Creator> in_cube(.5, random);

    int n = 10000;
    std::vector<Point> pts;

    PDT PT1, PT2, PT3;

    // Generating n random points
    for (int i=0 ; i < n ; i++) {
        Point p = *in_cube;
        in_cube++;
        pts.push_back(Point(p.x()+.5,p.y()+.5,p.z()+.5));
    }

    // Standard insertion
    t.start();
    for (int i=0 ; i < n ; i++) {
        PT1.insert(pts[i]);
    }
    t.stop();
    std::cout<<"  Time: "<<t.time()<<" sec. (Standard
        insertion)"<<std::endl;
    t.reset();

    // Iterator range insertion using spatial sorting but no dummy points
    t.start();
    PT2.insert(pts.begin(), pts.end()); // third parameter defaults to
        false
    t.stop();
    std::cout<<"  Time: "<<t.time()<<" sec. (with spatial
        sorting)"<<std::endl;
    t.reset();

    // Iterator range insertion using spatial sorting and dummy point
        heuristic
    t.start();
    PT3.insert(pts.begin(), pts.end(), true);
    t.stop();

```

```

std::cout<<"   Time: "<<t.time()<<" sec. (Dummy point
    heuristic)"<<std::endl;

return 0;
}

```

File: examples/Periodic_3_triangulation_3/large_point_set.cpp

39.6.5 Geometric Access

There might be applications that need the geometric primitives of a triangulation as an input but do not require a simplicial complex. For these cases we provide the geometric iterators that return only the geometric primitives fulfilling some properties. In the following example we use the *Periodic_triangle_iterator* with the option *UNIQUE_COVER_DOMAIN*. This means that only those triangles are returned that have a non-empty intersection with the original domain of the 1-sheeted covering space, see Figure 39.4 (Page 2597). The *Periodic_triangle* is actually a three-dimensional array of point-offset pairs. We check for all three entries of the periodic triangle whether the offset is (0,0,0) using the method *is_null*. If so, we convert the periodic triangle to a *PK::Triangle_3*, which requires *exact constructions* to be exact.

```

#include <CGAL/Exact_predicates_inexact_constructions_kernel.h>
#include <CGAL/Periodic_3_triangulation_traits_3.h>
#include <CGAL/Periodic_3_Delaunay_triangulation_3.h>

typedef CGAL::Exact_predicates_inexact_constructions_kernel K;
typedef CGAL::Periodic_3_triangulation_traits_3<K>          PK;
typedef CGAL::Periodic_3_Delaunay_triangulation_3<PK>       P3DT3;

typedef PK::Point_3      Point;
typedef PK::Triangle_3   Triangle;

typedef P3DT3::Periodic_triangle      Periodic_triangle;
typedef P3DT3::Periodic_triangle_iterator Periodic_triangle_iterator;
typedef P3DT3::Iterator_type          Iterator_type;

int main() {
    P3DT3 T;

    T.insert(Point(0,0,0));
    T.insert(Point(0,0,0.5));
    T.insert(Point(0,0.5,0.5));
    T.insert(Point(0.5,0,0.5));

    Periodic_triangle pt;
    Triangle t_bd;

    // Extracting the triangles that have a non-empty intersection with
    // the original domain of the 1-sheeted covering space
    for (Periodic_triangle_iterator ptit =
        T.periodic_triangles_begin(P3DT3::UNIQUE_COVER_DOMAIN);
        ptit != T.periodic_triangles_end(P3DT3::UNIQUE_COVER_DOMAIN);
        ++ptit) {
        pt = *ptit;
    }
}

```

```

    if (! (pt[0].second.is_null() && pt[1].second.is_null() &&
pt[2].second.is_null()) ) {
        // Convert the current Periodic_triangle to a Triangle if it is
        // not strictly contained inside the original domain.
        // Note that this requires EXACT constructions to be exact!
        t_bd = T.construct_triangle(pt);
    }
}
}

```

File: examples/Periodic_3_triangulation_3/geometric_access.cpp

39.6.6 Periodic Alpha Shapes

It is possible to use *Periodic_3_Delaunay_triangulation_3* as underlying triangulation for computing alpha shapes (cf. Chapter 41). For an example see Section 41.4.4.

39.7 Design and Implementation History

In 2006, Nico Kruithof started to work with Monique Teillaud on the 3D Periodic Triangulations package.

In 2007, Manuel Caroli continued work on the algorithms [CT09] and on the package with Monique Teillaud.

The package follows the design of the 3D Triangulations package (see Chapter 37).

3D Periodic Triangulations

Reference Manual

Manuel Caroli and Monique Teillaud

The main classes of the 3D Periodic Triangulation package are *Periodic_3_triangulation_3* and *Periodic_3_Delaunay_triangulation_3*. They contain functionality to access triangulations and to run queries on them. *Periodic_3_Delaunay_triangulation_3* can construct and modify Delaunay triangulations. It takes the geometric traits as well as the triangulation data structure as template parameters.

The geometric traits class must be a model of the concept *Periodic_3DelaunayTriangulationTraits_3*. It contains all predicates and constructions that are needed by the functions in the triangulation classes.

The package uses *Triangulation_data_structure_3* to represent the triangulation. The cells and vertices need to be models of the concepts *Periodic_3TriangulationDSCellBase_3* and *Periodic_3TriangulationDSVertexBase_3*, respectively. A triangulation is stored as a collection of vertices and cells that are linked together through incidence and adjacency relations. Each cell gives access to its four incident vertices and to its four adjacent cells. Each vertex gives access to one of its incident cells.

The four vertices of a cell are indexed with 0, 1, 2 and 3 in positive orientation, the positive orientation being defined by the orientation of the underlying space \mathbb{T}_c^3 . The neighbors of a cell are also indexed with 0, 1, 2, 3 in such a way that the neighbor indexed by i is opposite to the vertex with the same index. See Figure 39.2.

In order to be able to specify the tetrahedra that contain vertices both inside and outside the original domain we store an additional offset information in each vertex of a cell. These offsets are models of the concept *Periodic_3Offset_3*.

CGAL::Periodic_3_triangulation_3<PT,TDS>

Definition

The class *Periodic_triangulation_3* represents a 3-dimensional triangulation of a point set in \mathbb{T}_c^3 .

```
#include <CGAL/Periodic_3_triangulation_3.h>
```

Parameters

The first template argument *PT* must be a model of the *Periodic_3DelaunayTriangulationTraits_3* concept.

The second template argument *TDS* must be a model of the *TriangulationDataStructure_3* concept with some additional functionality in cells and vertices. Its default value is *Triangulation_data_structure_3<Triangulation_vertex_base_3<PT,Periodic_3_triangulation_ds_vertex_base_3<>>,Triangulation_cell_base_3<PT,Periodic_3_triangulation_ds_cell_base_3<>>>>*.

Types

The class *Triangulation_3* defines the following types:

<code>typedef PT</code>	<code>Geometric_traits;</code>	
<code>typedef TDS</code>	<code>Triangulation_data_structure;</code>	
<code>typedef Geometric_traits::Periodic_3_offset_3</code>	<code>Offset;</code>	
<code>typedef Geometric_traits::Iso_cuboid_3</code>	<code>Iso_cuboid;</code>	A type representing an axis-aligned cuboid. It must be a model of <i>PT::Iso_cuboid_3</i> . Used to represent the original domain.
<code>typedef array<int,3></code>	<code>Covering_sheets;</code>	Integer triple to store the number of sheets in each direction of space.
<code>typedef Geometric_traits::Point_3</code>	<code>Point;</code>	
<code>typedef Geometric_traits::Segment_3</code>	<code>Segment;</code>	
<code>typedef Geometric_traits::Triangle_3</code>	<code>Triangle;</code>	
<code>typedef Geometric_traits::Tetrahedron_3</code>	<code>Tetrahedron;</code>	
<code>typedef std::pair< Point, Offset ></code>	<code>Periodic_point;</code>	Represents a point-offset pair. The point in the pair lies in the original domain.
<code>typedef array< Periodic_point, 2></code>	<code>Periodic_segment;</code>	
<code>typedef array< Periodic_point, 3></code>	<code>Periodic_triangle;</code>	
<code>typedef array< Periodic_point, 4></code>	<code>Periodic_tetrahedron;</code>	

Only vertices (0-faces) and cells (3-faces) are stored. Edges (1-faces) and facets (2-faces) are not explicitly represented and thus there are no corresponding classes (see Section 39.2).

```
typedef Triangulation_data_structure::Vertex Vertex;
typedef Triangulation_data_structure::Cell Cell;
typedef Triangulation_data_structure::Edge Edge;
```

typedef Triangulation_data_structure::Facet Facet;

The vertices and faces of the triangulations are accessed through *handles*, *iterators* and *circulators*. A handle is a type which supports the two dereference operators *operator** and *operator->*. The Handle concept is documented in the support library. Iterators and circulators are bidirectional and non-mutable. The edges and facets of the triangulation can also be visited through iterators and circulators which are bidirectional and non-mutable.

Iterators and circulators are convertible to the corresponding handles, thus the user can pass them directly as arguments to the functions.

<i>typedef Triangulation_data_structure::Vertex_handle</i>	<i>Vertex_handle;</i>	handle to a vertex
<i>typedef Triangulation_data_structure::Cell_handle</i>	<i>Cell_handle;</i>	handle to a cell
<i>typedef Triangulation_data_structure::size_type</i>	<i>size_type;</i>	Size type (an unsigned integral type)
<i>typedef Triangulation_data_structure::difference_type</i>	<i>difference_type;</i>	Difference type (a signed integral type)
<i>typedef Triangulation_data_structure::Cell_iterator</i>	<i>Cell_iterator;</i>	iterator over cells
<i>typedef Triangulation_data_structure::Facet_iterator</i>	<i>Facet_iterator;</i>	iterator over facets
<i>typedef Triangulation_data_structure::Edge_iterator</i>	<i>Edge_iterator;</i>	iterator over edges
<i>typedef Triangulation_data_structure::Vertex_iterator</i>	<i>Vertex_iterator;</i>	iterator over vertices
<i>Periodic_3_triangulation_3<PT,TDS>:: Unique_vertex_iterator</i>		iterator over the vertices whose corresponding points lie in the original domain, i.e. for each set of periodic copies the <i>Unique_vertex_iterator</i> iterates over exactly one representative.
<i>typedef Triangulation_data_structure::Cell_circulator</i>	<i>Cell_circulator;</i>	circulator over all cells incident to a given edge
<i>typedef Triangulation_data_structure::Facet_circulator</i>	<i>Facet_circulator;</i>	circulator over all facets incident to a given edge

Geometric iterators:

<i>Periodic_3_triangulation_3<PT,TDS>:: Periodic_tetrahedron_iterator</i>	iterator over the tetrahedra corresponding to cells of the triangulation.
<i>Periodic_3_triangulation_3<PT,TDS>:: Periodic_triangle_iterator</i>	iterator over the triangles corresponding to facets of the triangulation.
<i>Periodic_3_triangulation_3<PT,TDS>:: Periodic_segment_iterator</i>	iterator over the segments corresponding to edges of the triangulation.
<i>Periodic_3_triangulation_3<PT,TDS>:: Periodic_point_iterator</i>	iterator over the points corresponding to vertices of the triangulation.

Enums:

The triangulation class also defines the following enum types:

To specify which case occurs when locating a point in the triangulation.

enum Locate_type { VERTEX=0, EDGE, FACET, CELL, EMPTY};

To specify the behavior of geometric iterators.

enum Iterator_type { STORED=0, UNIQUE, STORED_COVER_DOMAIN, UNIQUE_COVER_DOMAIN};

Creation

Periodic_3_triangulation_3<PT,TDS> *t*(*Iso_cuboid domain* = *Iso_cuboid*(0,0,0,1,1,1),
Geometric_traits traits = *Geometric_traits*())

Introduces an empty triangulation *t* with *domain* as original domain.

Precondition: *domain* is a cube.

Periodic_3_triangulation_3<PT,TDS> *t*(*Periodic_3_triangulation_3 tr*);

Copy constructor. All vertices and faces are duplicated.

Assignment

Periodic_3_triangulation_3 & *t* = *Periodic_3_triangulation_3 tr*

The triangulation *tr* is duplicated, and modifying the copy after the duplication does not modify the original. The previous triangulation held by *t* is deleted.

void *t.swap*(*Periodic_3_triangulation_3* & *tr*)

The triangulations *tr* and *t* are swapped. *t.swap(tr)* should be preferred to *t = tr* or to *t(tr)* if *tr* is deleted after that. Indeed, there is no copy of cells and vertices, thus this method runs in constant time.

void *t.clear*() Deletes all vertices and all cells of *t*.

template < *class PT*, *class TDS1*, *class TDS2* >
bool *operator==*(*Periodic_3_triangulation_3*<PT, TDS1> *t1*,
Periodic_3_triangulation_3<PT, TDS2> *t2*)

Equality operator. Returns true iff there exist a bijection between the vertices of *t1* and those of *t2* and a bijection between the cells of *t1* and those of *t2*, which preserve the geometry of the triangulation, that is, the points of each corresponding pair of vertices are equal, and the tetrahedra corresponding to each pair of cells are equal (up to a permutation of their vertices).

template < *class PT*, *class TDS1*, *class TDS2* >

```
bool operator!=( Periodic_3_triangulation_3<PT, TDS1> t1,
                Periodic_3_triangulation_3<PT, TDS2> t2)
```

The opposite of *operator==*.

Access Functions

<i>Geometric_traits</i>	<i>t.geom_traits()</i>	Returns a const reference to the geometric traits object.
-------------------------	------------------------	---

<i>Triangulation_data_structure</i>	<i>t.tds()</i>	Returns a const reference to the triangulation data structure.
-------------------------------------	----------------	--

<i>Iso_cuboid</i>	<i>t.domain()</i>	Returns the original domain.
-------------------	-------------------	------------------------------

_____ *advanced* _____

<i>Covering_sheets</i>	<i>t.number_of_sheets()</i>	Returns the number of sheets of the covering space the triangulation is currently computed in.
------------------------	-----------------------------	--

Non const access

```
void t.set_domain( const Iso_cuboid dom)
```

Changes the domain. Note that this function calls *clear()*, i.e., it erases the existing triangulation.

The responsibility of keeping a valid triangulation belongs to the user when using advanced operations allowing a direct manipulation of the *tds*. This method is mainly a help for users implementing their own triangulation algorithms.

<i>Triangulation_data_structure</i> &	<i>t.tds()</i>	Returns a reference to the triangulation data structure.
---------------------------------------	----------------	--

Non-constant-time queries and conversions

<code>bool t.is_extensible_triangulation_in_1_sheet_h1()</code>	<p>The current triangulation remains a triangulation in the 1-sheeted covering space even after adding points if this method returns <i>true</i>. This test relies on a heuristic, i.e. if it answers <i>false</i> nothing is known. This test runs in constant-time when not computing in the 1-sheeted covering space. (This test uses the length of the longest edge in the triangulation as a criterion [CT09].)</p>
---	--

<code>bool t.is_extensible_triangulation_in_1_sheet_h2()</code>	The same as <code>is_extensible_triangulation_in_1_sheet_h1()</code> but with a more precise heuristic, i.e. it might answer <i>true</i> in cases in which <code>is_extensible_triangulation_in_1_sheet_h1()</code> would not. However, it is much less time efficient when not computing in the 1-sheeted covering space. (This test uses the diameter of the largest empty ball in the input point set as a criterion [CT09].)
---	--

<i>bool</i> <i>t.is_triangulation_in_1_sheet()</i>	Returns <i>true</i> if the current triangulation would still be a triangulation in the 1-sheeted covering space, returns <i>false</i> otherwise.
--	--

It is not recommended to interfere with the built-in covering management. Especially a premature conversion to the 1-sheeted covering space might lead to problems when modifying the triangulation later.

<i>void</i> <i>t.convert_to_1_sheeted_covering()</i>	Converts the current triangulation into the same periodic triangulation in the 1-sheeted covering space.
--	--

<i>void</i> <i>t.convert_to_27_sheeted_covering()</i>	Converts the current triangulation into the same periodic triangulation in the 27-sheeted covering space.
---	---

└────────── advanced ─────────┘

<i>size_type</i> <i>t.number_of_vertices()</i>	Returns the number of vertices. Counts all vertices that are representatives of the same point in \mathbb{T}_c^3 as one vertex.
--	---

<i>size_type</i> <i>t.number_of_cells()</i>	Returns the number of cells. Counts all cells that are representatives of the same tetrahedron in \mathbb{T}_c^3 as one cell.
---	---

└────────── advanced ─────────┘

<i>size_type</i> <i>t.number_of_stored_vertices()</i>	Returns the number of vertices in the data structure. This is the same as the number of sheets times <i>number_of_vertices()</i> .
---	--

<i>size_type</i> <i>t.number_of_stored_cells()</i>	Returns the number of cells in the data structure. This is the same as the number of sheets times <i>number_of_cells()</i> .
--	--

└────────── advanced ─────────┘

Non-constant-time access functions

<i>size_type</i> <i>t.number_of_edges()</i>	Returns the number of edges. Counts all edges that are representatives of the same segment in \mathbb{T}_c^3 as one edge.
---	---

<i>size_type</i> <i>t.number_of_facets()</i>	Returns the number of facets. Counts all facets that are representatives of the same triangle in \mathbb{T}_c^3 as one facet.
--	---

└────────── advanced ─────────┘

<i>size_type</i> <i>t.number_of_stored_edges()</i>	Returns the number of edges in the data structure. This is the same as the number of sheets times <i>number_of_edges()</i> .
--	--

<i>size_type</i> <i>t.number_of_stored_facets()</i>	Returns the number of facets in the data structure. This is the same as the number of sheets times <i>number_of_facets()</i> .
---	--

└────────── advanced ─────────┘

Geometric access functions

<i>Periodic_point</i> <i>t.periodic_point(const Vertex_handle v)</i>	
---	--

Returns the periodic point given by vertex *v*. If *t* is represented in the 1-sheeted covering space, the offset is always zero. Otherwise *v* can correspond to a periodic copy outside *domain* of an input point.

<i>Periodic_point</i>	<i>t.periodic_point(const Cell_handle c, int i)</i>	<p>If <i>t</i> is represented in the 1-sheeted covering space, this function returns the periodic point given by the <i>i</i>-th vertex of cell <i>c</i>, that is the point in the original domain and the offset of the vertex in <i>c</i>. If <i>t</i> is represented in the 27-sheeted covering space, this offset is possibly added to another offset determining the periodic copy.</p> <p><i>Precondition:</i> $i \in \{0, 1, 2, 3\}$</p>
<i>Periodic_segment</i>	<i>t.periodic_segment(const Cell_handle c, int i, int j)</i>	<p>Returns the periodic segment formed by the two point-offset pairs corresponding to the two vertices of edge (c, i, j).</p> <p><i>Precondition:</i> $i, j \in \{0, 1, 2, 3\}, i \neq j$</p>
<i>Periodic_segment</i>	<i>t.periodic_segment(Edge e)</i>	<p>Same as the previous method for edge <i>e</i>.</p>
<i>Periodic_triangle</i>	<i>t.periodic_triangle(const Cell_handle c, int i)</i>	<p>Returns the periodic triangle formed by the three point-offset pairs corresponding to the three vertices of facet (c, i). The triangle is oriented so that its normal points to the inside of cell <i>c</i>.</p> <p><i>Precondition:</i> $i \in \{0, 1, 2, 3\}$</p>
<i>Periodic_triangle</i>	<i>t.periodic_triangle(Facet f)</i>	<p>Same as the previous method for facet <i>f</i>.</p>
<i>Periodic_tetrahedron</i>	<i>t.periodic_tetrahedron(const Cell_handle c)</i>	<p>Returns the periodic tetrahedron formed by the four point-offset pairs corresponding to the four vertices of <i>c</i>.</p>

Note that a traits class providing exact constructions should be used in order to guarantee the following operations to be exact (as opposed to computing the triangulation only, which requires only exact predicates).

<i>Point</i>	<i>t.point(Periodic_point p)</i>	<p>Converts the <i>Periodic_point</i> <i>s</i> (point-offset pair) to the corresponding <i>Point</i> in \mathbb{R}^3.</p>
<i>Segment</i>	<i>t.segment(Periodic_segment s)</i>	<p>Converts the <i>Periodic_segment</i> <i>s</i> to a <i>Segment</i>.</p>
<i>Triangle</i>	<i>t.triangle(Periodic_triangle t)</i>	<p>Converts the <i>Periodic_triangle</i> <i>t</i> to a <i>Triangle</i>.</p>
<i>Tetrahedron</i>	<i>t.tetrahedron(Periodic_tetrahedron t)</i>	<p>Converts the <i>Periodic_tetrahedron</i> <i>t</i> to a <i>Tetrahedron</i>.</p>

Queries

bool t.is_vertex(Point p, Vertex_handle & v)

Tests whether p is a vertex of t by locating p in the triangulation. If p is found, the associated vertex v is given.

bool t.is_vertex(Vertex_handle v)

Tests whether v is a vertex of t .

bool t.is_edge(Vertex_handle u, Vertex_handle v, Cell_handle & c, int & i, int & j)

Tests whether (u,v) is an edge of t . If the edge is found, it gives a cell c having this edge and the indices i and j of the vertices u and v in c , in this order.

Precondition: u and v are vertices of t .

bool t.is_edge(Vertex_handle u, Offset offu, Vertex_handle v, Offset offv, Cell_handle & c, int & i, int & j)

Tests whether $((u,offu),(v,offv))$ is an edge of t . If the edge is found, it gives a cell c having this edge and the indices i and j of the vertices u and v in c , in this order.

Precondition: u and v are vertices of t .

bool t.is_facet(Vertex_handle u, Vertex_handle v, Vertex_handle w, Cell_handle & c, int & i, int & j, int & k)

Tests whether (u,v,w) is a facet of t . If the facet is found, it computes a cell c having this facet and the indices i, j and k of the vertices u, v and w in c , in this order.

Precondition: u, v and w are vertices of t .

*bool t.is_facet(Vertex_handle u,
Offset offu,
Vertex_handle v,
Offset offv,
Vertex_handle w,
Offset offw,
Cell_handle & c,
int & i,
int & j,
int & k)*

Tests whether $((u,offu),(v,offv),(w,offw))$ is a facet of t . If the facet is found, it computes a cell c having this facet and the indices i, j and k of the vertices u, v and w in c , in this order.

Precondition: u, v and w are vertices of t .

bool t.is_cell(Cell_handle c)

Tests whether c is a cell of t .

*bool t.is_cell(Vertex_handle u,
Vertex_handle v,
Vertex_handle w,
Vertex_handle x,
Cell_handle & c,
int & i,
int & j,
int & k,*

int & l)

Tests whether (u,v,w,x) is a cell of t . If the cell c is found, the method computes the indices i, j, k and l of the vertices u, v, w and x in c , in this order.

Precondition: u, v, w and x are vertices of t .

bool t.is_cell(Vertex_handle u, Vertex_handle v, Vertex_handle w, Vertex_handle x, Cell_handle & c)

Tests whether (u,v,w,x) is a cell of t and computes this cell c .

Precondition: u, v, w and x are vertices of t .

*bool t.is_cell(Vertex_handle u,
Offset offu,
Vertex_handle v,
Offset offv,
Vertex_handle w,
Offset offw,
Vertex_handle x,
Offset offx,
Cell_handle & c,
int & i,
int & j,
int & k,
int & l)*

Tests whether $((u,offu),(v,offv),(w,offw),(x,offx))$ is a cell of t . If the cell c is found, the method computes the indices i, j, k and l of the vertices u, v, w and x in c , in this order.

Precondition: u, v, w and x are vertices of t .

*bool t.is_cell(Vertex_handle u,
Offset offu,
Vertex_handle v,
Offset offv,
Vertex_handle w,
Offset offw,
Vertex_handle x,
Offset offx,
Cell_handle & c)*

Tests whether $((u,offu),(v,offv),(w,offw),(x,offx))$ is a cell of t and computes this cell c .

Precondition: u, v, w and x are vertices of t .

There is a method *has_vertex* in the cell class. The analogous methods for facets are defined here.

bool t.has_vertex(Facet f, Vertex_handle v, int & j)

If v is a vertex of f , then j is the index of v in the cell $f.first$, and the method returns *true*.

bool t.has_vertex(Cell_handle c, int i, Vertex_handle v, int & j)

Same for facet (c,i) . Computes the index j of v in c .

bool t.has_vertex(Facet f, Vertex_handle v)

bool t.has_vertex(Cell_handle c, int i, Vertex_handle v)

Same as the first two methods, but these two methods do not return the index of the vertex.

The following three methods test whether two facets have the same vertices.

bool t.are_equal(Cell_handle c, int i, Cell_handle n, int j)

bool t.are_equal(Facet f, Facet g)

bool t.are_equal(Facet f, Cell_handle n, int j)

Point location

The class *Periodic_3_triangulation_3*<*PT*,*TDS*> provides three functions to locate a given point with respect to a triangulation. It provides also functions to test if a given point is inside a face or not. Note that the class *Periodic_3_Delaunay_triangulation_3* also provides a *nearest_vertex()* function.

Cell_handle t.locate(Point query, Cell_handle start = Cell_handle())

Returns the cell that contains the query in its interior. If *query* lies on a facet, an edge or on a vertex, one of the cells having *query* on its boundary is returned.

The optional argument *start* is used as a starting place for the search.

Precondition: query lies in the original domain *domain*.

Cell_handle t.locate(Point query, Locate_type & lt, int & li, int & lj, Cell_handle start = Cell_handle())

The *k*-face that contains *query* in its interior is returned, by means of the cell returned together with *lt*, which is set to the locate type of the query (*VERTEX*, *EDGE*, *FACET*, *CELL*) and two indices *li* and *lj* that specify the *k*-face of the cell containing *query*.

If the *k*-face is a cell, *li* and *lj* have no meaning; if it is a facet (resp. vertex), *li* gives the index of the facet (resp. vertex) and *lj* has no meaning; if it is an edge, *li* and *lj* give the indices of its vertices.

If there is no vertex in the triangulation yet, *lt* is set to *EMPTY* and *locate* returns the default constructed handle.

The optional argument *start* is used as a starting place for the search.

Precondition: query lies in the original domain *domain*.

Bounded_side t.side_of_cell(Point p, Cell_handle c, Locate_type & lt, int & li, int & lj)

Returns a value indicating on which side of the oriented boundary of *c* the point *p* lies. More precisely, it returns:

- *ON_BOUNDED_SIDE* if *p* is inside the cell.

- *ON_BOUNDARY* if *p* on the boundary of the cell. Then *lt* together with *li* and *lj* give the precise location on the boundary. (See the descriptions of the *locate* methods.)

- *ON_UNBOUNDED_SIDE* if *p* lies outside the cell.

Precondition: query lies in the original domain *domain*.

Traversal of the Triangulation

The periodic triangulation class provides several iterators and circulators that allow one to traverse it.

Cell, Face, Edge and Vertex Iterators

The following iterators allow the user to visit cells, facets, edges and vertices of the stored triangulation, i.e. in case of computing in a multiply sheeted covering space all stored periodic copies of each item are returned. These iterators are non-mutable, bidirectional and their value types are respectively *Cell*, *Facet*, *Edge* and *Vertex*. They are all invalidated by any change in the triangulation.

<i>Vertex_iterator</i>	<i>t.vertices_begin()</i>	Starts at an arbitrary vertex. Iterates over all vertices. Returns <i>vertices_end()</i> if <i>t.number_of_vertices() = 0</i> .
<i>Vertex_iterator</i>	<i>t.vertices_end()</i>	Past-the-end iterator
<i>Edge_iterator</i>	<i>t.edges_begin()</i>	Starts at an arbitrary edge. Iterates over all edges. Returns <i>edges_end()</i> if <i>t.number_of_vertices() = 0</i> .
<i>Edge_iterator</i>	<i>t.edges_end()</i>	Past-the-end iterator
<i>Facet_iterator</i>	<i>t.facets_begin()</i>	Starts at an arbitrary facet. Iterates over all facets. Returns <i>facets_end()</i> if <i>t.number_of_vertices() = 0</i> .
<i>Facet_iterator</i>	<i>t.facets_end()</i>	Past-the-end iterator
<i>Cell_iterator</i>	<i>t.cells_begin()</i>	Starts at an arbitrary cell. Iterates over all cells. Returns <i>cells_end()</i> if <i>t.number_of_vertices() = 0</i> .
<i>Cell_iterator</i>	<i>t.cells_end()</i>	Past-the-end iterator
<i>Unique_vertex_iterator</i>	<i>t.unique_vertices_begin()</i>	Starts at an arbitrary vertex. Iterates over all vertices whose corresponding points lie in the original domain, i.e. for each set of periodic copies the <i>Unique_vertex_iterator</i> iterates over exactly one representative. Returns <i>unique_vertices_end()</i> if <i>t.number_of_vertices() = 0</i> .
<i>Unique_vertex_iterator</i>	<i>t.unique_vertices_end()</i>	Past-the-end iterator

Geometric iterators

The following iterators allow the user to obtain geometric primitives corresponding to cells, facets, edges, and vertices of the triangulation. These iterators are non-mutable, bidirectional and their value types are respectively *Periodic_point*, *Periodic_segment*, *Periodic_triangle*, and *Periodic_tetrahedron*. They are all invalidated by any change in the triangulation. If the periodic triangulation is not computed in the 1-sheeted covering space, these iterators can be used to retain only the geometric primitives in the original domain. This can be controlled using the enum *Iterator_type*, see page [2622](#).

Periodic_point_iterator *t.periodic_points_begin(Iterator_type it = STORED)*

Iterates over the points of the triangulation. Its behavior is defined by the *Iterator_type* *it* as described on page [2622](#).

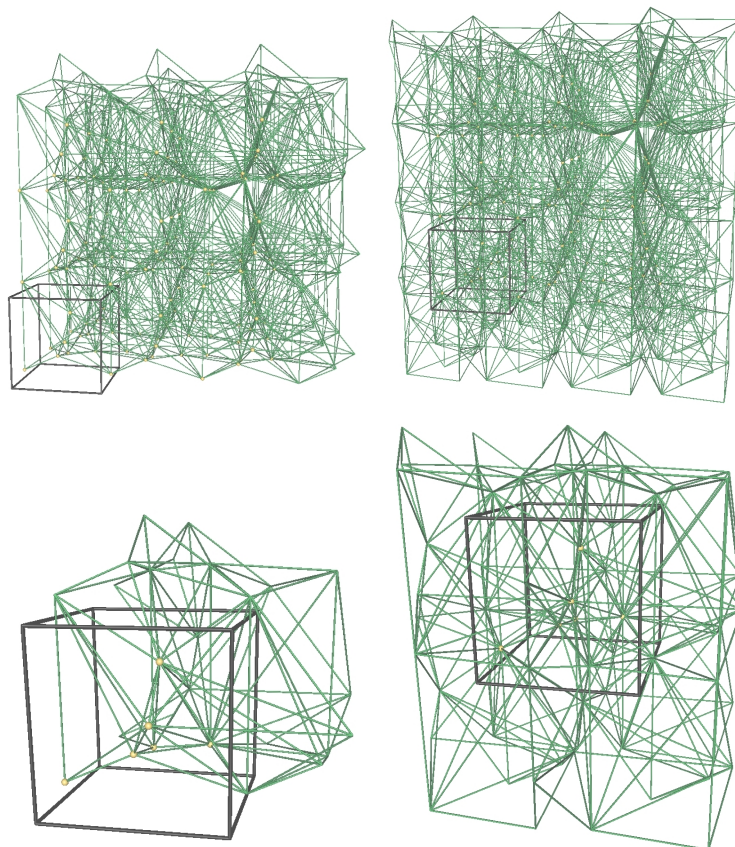

Figure 39.4: The four different modes of the geometric iterators: `STORED`, `STORED_COVER_DOMAIN`, `UNIQUE`, `UNIQUE_COVER_DOMAIN`. Note that in case of computing in the 1-sheeted covering space, `STORED` and `UNIQUE` give the same result.

<i>Periodic_point_iterator</i>	<i>t.periodic_points_end(Iterator_type it = STORED)</i>	Past-the-end iterator. Note that to match another <i>Periodic_point_iterator</i> both must have the same <i>Iterator_type it</i> .
<i>Periodic_segment_iterator</i>	<i>t.periodic_segments_begin(Iterator_type it = STORED)</i>	Iterates over the segments of the triangulation. Its behavior is defined by the <i>Iterator_type it</i> as described on page 2622.
<i>Periodic_segment_iterator</i>	<i>t.periodic_segments_end(Iterator_type it = STORED)</i>	Past-the-end iterator. Note that to match another <i>Periodic_segment_iterator</i> both must have the same <i>Iterator_type it</i> .
<i>Periodic_triangle_iterator</i>	<i>t.periodic_triangles_begin(Iterator_type it = STORED)</i>	Iterates over the triangles of the triangulation. Its behavior is defined by the <i>Iterator_type it</i> as described on page 2622.
<i>Periodic_triangle_iterator</i>	<i>t.periodic_triangles_end(Iterator_type it = STORED)</i>	Past-the-end iterator. Note that to match another <i>Periodic_triangle_iterator</i> both must have the same <i>Iterator_type it</i> .
<i>Periodic_tetrahedron_iterator</i>	<i>t.periodic_tetrahedra_begin(Iterator_type it = STORED)</i>	Iterates over the tetrahedra of the triangulation. Its behavior is defined by the <i>Iterator_type it</i> as described on page 2622.
<i>Periodic_tetrahedron_iterator</i>	<i>t.periodic_tetrahedra_end(Iterator_type it = STORED)</i>	Past-the-end iterator. Note that to match another <i>Periodic_tetrahedron_iterator</i> both must have the same <i>Iterator_type it</i> .

Cell and Facet Circulators

The following circulators respectively visit all cells or all facets incident to a given edge. They are non-mutable and bidirectional. They are invalidated by any modification of one of the cells traversed.

<i>Cell_circulator</i>	<i>t.incident_cells(Edge e)</i>	Starts at an arbitrary cell incident to <i>e</i> .
<i>Cell_circulator</i>	<i>t.incident_cells(Cell_handle c, int i, int j)</i>	As above for edge <i>(i,j)</i> of <i>c</i> .
<i>Cell_circulator</i>	<i>t.incident_cells(Edge e, Cell_handle start)</i>	Starts at cell <i>start</i> . <i>Precondition: start</i> is incident to <i>e</i> .
<i>Cell_circulator</i>	<i>t.incident_cells(Cell_handle c, int i, int j, Cell_handle start)</i>	As above for edge <i>(i,j)</i> of <i>c</i> .
<i>Facet_circulator</i>	<i>t.incident_facets(Edge e)</i>	Starts at an arbitrary facet incident to <i>e</i> .
<i>Facet_circulator</i>	<i>t.incident_facets(Cell_handle c, int i, int j)</i>	As above for edge <i>(i,j)</i> of <i>c</i> .
<i>Facet_circulator</i>	<i>t.incident_facets(Edge e, Facet start)</i>	Starts at facet <i>start</i> . <i>Precondition: start</i> is incident to <i>e</i> .

Facet_circulator *t.incident_facets(Edge e, Cell_handle start, int f)*

Starts at facet of index *f* in *start*.

Facet_circulator *t.incident_facets(Cell_handle c, int i, int j, Facet start)*

As above for edge (*i,j*) of *c*.

Facet_circulator *t.incident_facets(Cell_handle c, int i, int j, Cell_handle start, int f)*

As above for edge (*i,j*) of *c* and facet (*start,f*).

Traversal of the incident cells and facets, and the adjacent vertices of a given vertex

template <class OutputIterator>

OutputIterator *t.incident_cells(Vertex_handle v, OutputIterator cells)*

Copies the *Cell_handles* of all cells incident to *v* to the output iterator *cells*. Returns the resulting output iterator.

Precondition: *v* \neq *Vertex_handle()*, *t.is_vertex(v)*.

template <class OutputIterator>

OutputIterator *t.incident_facets(Vertex_handle v, OutputIterator facets)*

Copies the *Facets* incident to *v* to the output iterator *facets*. Returns the resulting output iterator.

Precondition: *v* \neq *Vertex_handle()*, *t.is_vertex(v)*.

template <class OutputIterator>

OutputIterator *t.incident_edges(Vertex_handle v, OutputIterator edges)*

Copies the *Edges* incident to *v* to the output iterator *edges*. Returns the resulting output iterator.

Precondition: *v* \neq *Vertex_handle()*, *t.is_vertex(v)*.

template <class OutputIterator>

OutputIterator *t.adjacent_vertices(Vertex_handle v, OutputIterator vertices)*

Copies the *Vertex_handles* of all vertices adjacent to *v* to the output iterator *vertices*. Returns the resulting output iterator.

Precondition: *v* \neq *Vertex_handle()*, *t.is_vertex(v)*.

size_type *t.degree(Vertex_handle v)*

Returns the degree of a vertex, that is, the number of adjacent vertices.

Precondition: *v* \neq *Vertex_handle()*, *t.is_vertex(v)*.

Traversal between adjacent cells

<i>int</i>	<i>t.mirror_index(Cell_handle c, int i)</i>	Returns the index of <i>c</i> in its i^{th} neighbor. <i>Precondition:</i> $i \in \{0, 1, 2, 3\}$.
<i>Vertex_handle</i>	<i>t.mirror_vertex(Cell_handle c, int i)</i>	Returns the vertex of the i^{th} neighbor of <i>c</i> that is opposite to <i>c</i> . <i>Precondition:</i> $i \in \{0, 1, 2, 3\}$.
<i>Facet</i>	<i>t.mirror_facet(Facet f)</i>	Returns the same facet viewed from the other adjacent cell.

advanced

Checking

The responsibility of keeping a valid triangulation belongs to the user when using advanced operations allowing a direct manipulation of cells and vertices. We provide the user with the following methods to help debugging.

bool *t.is_valid(bool verbose = false)*

Checks the combinatorial validity of the triangulation. Checks also the validity of its geometric embedding (see Section 39.2).
When *verbose* is set to true, messages describing the first invalidity encountered are printed.

bool *t.is_valid(Cell_handle c, bool verbose = false)*

Checks the combinatorial validity of the cell by calling the *is_valid* method of the *Triangulation_data_structure* cell class. Also checks the geometric validity of *c*, if *c* is finite. (See Section 39.2.)
When *verbose* is set to true, messages are printed to give a precise indication of the kind of invalidity encountered.

advanced

I/O

istream& *istream& is >> Periodic_3_triangulation_3 &t* Reads a triangulation from *is* and stores it in *t*.
Precondition: *is* has the below described format.

ostream& *ostream& os << Periodic_3_triangulation_3 t* Writes the triangulation *t* into *os*.

The information in the *iostream* is:

- the original domain
- the number of sheets of the covering space as in *number_of_sheets()*
- the number of vertices
- the non-combinatorial information of vertices (point resp. point-offset pairs, etc.)

- the number of cells
- the indices of the vertices of each cell
- the indices of the neighbors of each cell, where the index corresponds to the preceding list of cells
- the offsets corresponding to the vertices of the cells
- the non-combinatorial information of each cell

Periodic_3_Delaunay_triangulation_3

CGAL::Periodic_3_Delaunay_triangulation_3<PT,TDS>

Definition

The class *Periodic_3_Delaunay_triangulation_3* represents a Delaunay triangulation in three-dimensional periodic space.

```
#include <CGAL/Periodic_3_Delaunay_triangulation_3.h>
```

Parameters

The first template argument *PT* must be a model of the *Periodic_3DelaunayTriangulationTraits_3* concept.

The second template argument *TDS* must be a model of the *TriangulationDataStructure_3* concept with some additional functionality in cells and vertices. Its default value is *Triangulation_data_structure_3<Triangulation_vertex_base_3<PT,Periodic_3_triangulation_ds_vertex_base_3<>>,Triangulation_cell_base_3<PT,Periodic_3_triangulation_ds_cell_base_3<>>>>*.

Inherits From

Periodic_3_triangulation_3<Periodic_3DelaunayTriangulationTraits_3,TriangulationDataStructure_3>

Creation

```
Periodic_3_Delaunay_triangulation_3<PT,TDS> dt( Iso_cuboid domain = Iso_cuboid(0,0,0,1,1,1),
                                                Geom_traits traits = Geom_traits())
```

Creates an empty periodic Delaunay triangulation *dt*, with *domain* as original domain and possibly specifying a traits class *traits*.

Precondition: *domain* is a cube.

```
Periodic_3_Delaunay_triangulation_3<PT,TDS> dt( Periodic_3_Delaunay_triangulation_3 dt1);
```

Copy constructor.

```
template < class InputIterator >
```

```
Periodic_3_Delaunay_triangulation_3<PT,TDS> dt( InputIterator first,
                                                InputIterator last,
                                                Iso_cuboid domain = Iso_cuboid(0,0,0,1,1,1),
                                                Geom_traits traits = Geom_traits())
```

Equivalent to constructing an empty triangulation with the optional domain and traits class arguments and calling *insert(first,last)*.

Precondition: The *value_type* of *first* and *last* are *Points* lying inside *domain* and *domain* is a cube.

Operations

Insertion

The following methods insert points in the triangulation ensuring the empty sphere property of Delaunay triangulations. The inserted points need to lie in the original domain (see Section 39.1 of the user manual).

In the degenerate case when there are co-spherical points, the Delaunay triangulation is known not to be uniquely defined. In this case, CGAL chooses a particular Delaunay triangulation using a symbolic perturbation scheme [DT03].

Note that insertion of a new point can cause a switch from computing in the 27-sheeted covering space to computing in the 1-sheeted covering space, which invalidates some *Vertex_handles* and *Cell_handles*.

Vertex_handle *dt.insert(Point p, Cell_handle start = Cell_handle())*

Inserts point *p* in the triangulation and returns the corresponding vertex. The optional argument *start* is used as a starting place for the point location.

Precondition: *p* lies in the original domain *domain*.

Vertex_handle *dt.insert(Point p, Locate_type lt, Cell_handle loc, int li, int lj)*

Inserts point *p* in the triangulation and returns the corresponding vertex. Similar to the above *insert()* function, but takes as additional parameter the return values of a previous location query. See description of *Periodic_3_triangulation_3::locate()*.

Precondition: *p* lies in the original domain *domain*.

The following method allows one to insert several points. It returns the number of inserted points.

template < class InputIterator >

std::ptrdiff_t *dt.insert(InputIterator first, InputIterator last, bool is_large_point_set = false)*

Inserts the points in the iterator range *[first, last)*. Returns the number of inserted points. This function uses spatial sorting (cf. chapter 63.2) and therefore is not guaranteed to insert the points following the order of *InputIterator*. If the third argument *is_large_point_set* is set to *true* a heuristic for optimizing the insertion of large point sets is applied.

Precondition: The *value_type* of *first* and *last* are *Points* lying inside *domain*.

Point moving

Vertex_handle *dt.move_point(Vertex_handle v, Point p)*

Moves the point stored in *v* to *p*, while preserving the Delaunay property. This performs an action semantically equivalent to *remove(v)* followed by *insert(p)*, but is supposedly faster when the point has not moved much. Returns the handle to the new vertex.

Precondition: *p* lies in the original domain *domain*.

Removal

When a vertex v is removed from a triangulation, all the cells incident to v must be removed, and the polyhedral region consisting of all the tetrahedra that are incident to v must be re-triangulated. So, the problem reduces to triangulating a polyhedral region, while preserving its boundary, or to compute a *constrained* triangulation. This is known to be sometimes impossible: the Schönhardt polyhedron cannot be triangulated [She98].

However, when dealing with Delaunay triangulations, the case of such polyhedra that cannot be re-triangulated cannot happen, so CGAL proposes a vertex removal.

void *dt.remove(Vertex_handle v)*

Removes the vertex v from the triangulation. When computing in the 27-sheeted covering space it removes all 27 copies of v .

template < class InputIterator >

std::ptrdiff_t dt.remove(InputIterator first, InputIterator beyond)

Removes the vertices specified by the iterator range (*first*, *beyond*) of value type *Vertex_handle*. *remove()* is called for each element of the range. The number of vertices removed is returned; this number does not account for periodic copies of removed vertices.

Precondition: The iterator must not iterate over several periodic copies of the same vertex, use e.g. the *Unique_vertex_iterator*.

Queries

Bounded_side dt.side_of_sphere(Cell_handle c, Point p, Offset off = Offset(0,0,0))

Returns a value indicating on which side of the circumscribed sphere of c the point-offset pair (p, off) lies. More precisely, it returns:

- *ON_BOUNDED_SIDE* if (p, off) is inside the sphere.
- *ON_BOUNDARY* if (p, off) on the boundary of the sphere.
- *ON_UNBOUNDED_SIDE* if (p, off) lies outside the sphere.

Precondition: p lies in the original domain *domain*.

Vertex_handle dt.nearest_vertex(Point p, Cell_handle c = Cell_handle())

Returns any nearest vertex to the point p , or the default constructed handle if the triangulation is empty. The optional argument c is a hint specifying where to start the search. It always returns a vertex corresponding to a point inside *domain* even if computing in a multiply sheeted covering space.

Precondition: c is a cell of dt and p lies in the original domain *domain*.

Vertex_handle dt.nearest_vertex_in_cell(Cell_handle c, Point p, Offset off = Offset(0,0,0))

Returns the vertex of the cell c that is nearest to the point-offset pair (p, off) .

Precondition: p lies in the original domain *domain*.

A point-offset pair (p, off) is said to be in conflict with a cell c iff *dt.side_of_sphere(c, p, off)* returns *ON_BOUNDED_SIDE*. The set of cells that are in conflict with (p, off) is star-shaped.

```
template <class OutputIteratorBoundaryFacets, class OutputIteratorCells, class OutputIteratorInternalFacets>
```

```
Triple<OutputIteratorBoundaryFacets, OutputIteratorCells, OutputIteratorInternalFacets>
```

```
dt.find_conflicts( Point p,
                  Cell_handle c,
                  OutputIteratorBoundaryFacets bfit,
                  OutputIteratorCells cit,
                  OutputIteratorInternalFacets ifit)
```

Computes the conflict hole induced by p . The starting cell c must be in conflict. Then this function returns respectively in the output iterators:

- cit : the cells in conflict.
- $bfit$: the facets on the boundary, that is, the facets (t, i) where the cell t is in conflict, but $t \rightarrow neighbor(i)$ is not.
- $ifit$: the facets inside the hole, that is, delimiting two cells in conflict.

Returns the pair composed of the resulting output iterators.

Precondition: c is in conflict with p and p lies in the original domain $domain$.

```
template <class OutputIterator>
```

```
OutputIterator
```

```
dt.vertices_in_conflict( Point p, Cell_handle c, OutputIterator res)
```

Similar to `find_conflicts()`, but reports the vertices which are on the boundary of the conflict hole of p , in the output iterator res . Returns the resulting output iterator.

Precondition: c is in conflict with p and p lies in the original domain $domain$.

A face (cell, facet or edge) is said to be a Gabriel face iff its smallest circumscribing sphere do not enclose any vertex of the triangulation. Any Gabriel face belongs to the Delaunay triangulation, but the reciprocal is not true. The following member functions test the Gabriel property of Delaunay faces.

```
bool dt.is_Gabriel( Cell_handle c, int i)
bool dt.is_Gabriel( Cell_handle c, int i, int j)
bool dt.is_Gabriel( Facet f)
bool dt.is_Gabriel( Edge e)
```

Voronoi diagram

CGAL offers several functions to display the Voronoi diagram of a set of points in 3D.

Note that a traits class providing exact constructions should be used in order to guarantee the computation of the Voronoi diagram (as opposed to computing the triangulation only, which requires only exact predicates).

<i>Point</i>	<code>dt.dual(Cell_handle c)</code>	Returns the representative of the circumcenter of the four vertices of c that lies in the original domain $domain$.
<i>Periodic_segment</i>	<code>dt.dual(Facet f)</code>	Returns the dual of facet f , which is a periodic segment.
<i>Periodic_segment</i>	<code>dt.dual(Cell_handle c, int i)</code>	same as the previous method for facet (c, i) . <i>Precondition:</i> $i \in \{0, 1, 2, 3\}$

```
template <class OutputIterator>
OutputIterator    dt.dual( Edge e, OutputIterator pts)
```

Returns in the output iterator the points of the dual polygon of edge e in the same order as the *Facet_circulator* returns facets incident to the edge e . The points form the dual polygon in \mathbb{R}^3 , so they do not necessarily all lie inside the original domain.

```
template <class OutputIterator>
OutputIterator    dt.dual( Cell_handle c, int i, int j, OutputIterator pts)
```

same as the previous method for edge (c,i,j) .
Precondition: $i, j \in \{0, 1, 2, 3\}, i \neq j$

```
template <class OutputIterator>
OutputIterator    dt.dual( Vertex_handle v, OutputIterator pts)
```

Returns in the output iterator the points of the dual polyhedron of vertex v in no particular order. The points form the dual polyhedron in \mathbb{R}^3 , so they do not necessarily lie all inside the original domain.

```
template <class Stream>
Stream&           dt.draw_dual( Stream & os)    Sends the set of duals to all the facets of  $dt$  into  $os$ .
```

```
Geom_traits::FT   dt.dual_volume( Vertex_handle v)
```

Returns the volume of the Voronoi cell dual to v .

```
Point             dt.dual_centroid( Vertex_handle v)
```

Returns the centroid of the Voronoi cell dual to v .

————— *advanced* —————

Checking

```
bool              dt.is_valid( bool verbose = false)
```

Checks the combinatorial validity of the triangulation and the validity of its geometric embedding (see Section 39.2). Also checks that all the circumscribing spheres of cells are empty.
When *verbose* is set to true, messages describing the first invalidity encountered are printed.

bool *dt.is_valid(Cell_handle c, bool verbose = false)*

Checks the combinatorial and geometric validity of the cell (see Section [39.2](#)). Also checks that the circumscribing sphere of cells is empty.

When *verbose* is set to true, messages are printed to give a precise indication of the kind of invalidity encountered.

These methods are mainly a debugging help for the users of advanced features.

Periodic_3_triangulation_3

CGAL::Periodic_3_triangulation_hierarchy_3<PTr>

Definition

The class *Periodic_3_triangulation_hierarchy_3* implements a triangulation augmented with a data structure which allows fast point location queries.

```
#include <CGAL/Periodic_3_triangulation_hierarchy_3.h>
```

Parameters

It is templated by a parameter which must be instantiated by one of the CGAL periodic triangulation classes. *In the current implementation, only Periodic_3_Delaunay_triangulation_3 is supported for PTr.*

PTr::Vertex has to be a model of the concept *Periodic_3TriangulationHierarchyVertexBase_3*.

PTr::Geom_traits has to be a model of the concept *Periodic_3DelaunayTriangulationTraits_3*.

Inherits From

PTr

Periodic_3_triangulation_hierarchy_3<PTr> offers exactly the same functionalities as *PTr*. Most of them (point location, insertion, removal...) are overloaded to improve their efficiency by using the hierarchic structure.

Note that, since the algorithms that are provided are randomized, the running time of constructing a triangulation with a hierarchy may be improved when shuffling the data points.

However, the I/O operations are not overloaded. So, writing a hierarchy into a file will lose the hierarchic structure and reading it from the file will result in an ordinary triangulation whose efficiency will be the same as *PTr*.

Implementation

The data structure is a hierarchy of triangulations. The triangulation at the lowest level is the original triangulation where operations and point location are to be performed. Then at each succeeding level, the data structure stores a triangulation of a small random sample of the vertices of the triangulation at the preceding level. Point location is done through a top-down nearest neighbor query. The nearest neighbor query is first performed naively in the top level triangulation. Then, at each following level, the nearest neighbor at that level is found through a linear walk performed from the nearest neighbor found at the preceding level. Because the number of vertices in each triangulation is only a small fraction of the number of vertices of the preceding triangulation the data structure remains small and achieves fast point location queries on real data.

CGAL::Periodic_3_Delaunay_triangulation_3

Periodic_3DelaunayTriangulationTraits_3

Definition

The concept `Periodic_3DelaunayTriangulationTraits_3` is the first template parameter of the classes `Periodic_3DelaunayTriangulation_3` and `Periodic_3Triangulation_3`. It refines the concept `DelaunayTriangulationTraits_3` from the CGAL 3D Triangulation (Page ??) package. It redefines the geometric objects, predicates and constructions to work with point-offset pairs. In most cases the offsets will be (0,0,0) and the predicates from `DelaunayTriangulationTraits_3` can be used directly. For efficiency reasons we maintain for each functor the version without offsets.

Refines

`DelaunayTriangulationTraits_3`

In addition to the requirements described for the traits class `DelaunayTriangulationTraits_3`, the geometric traits class of a Periodic Delaunay triangulation must fulfill the following requirements:

Types

`Periodic_3DelaunayTriangulationTraits_3::Point_3` The point type. It must be a model of `Kernel::Point_3`.

`Periodic_3DelaunayTriangulationTraits_3::Vector_3` The vector type. It must be a model of `Kernel::Vector_3`.

`Periodic_3DelaunayTriangulationTraits_3::Periodic_3_offset_3` The offset type. It must be a model of the concept `Periodic_3Offset_3`.

`Periodic_3DelaunayTriangulationTraits_3::Iso_cuboid_3` A type representing an axis-aligned cuboid. It must be a model of `Kernel::Iso_cuboid_3`.

The following three types represent geometric primitives in \mathbb{R}^3 . They are required to provide functions converting primitives from \mathbb{T}_c^3 to \mathbb{R}^3 , i.e. constructing representatives in \mathbb{R}^3 .

`Periodic_3DelaunayTriangulationTraits_3::Segment_3` A segment type. It must be a model of `Kernel::Segment_3`.

`Periodic_3DelaunayTriangulationTraits_3::Triangle_3` A triangle type. It must be a model of `Kernel::Triangle_3`.

`Periodic_3DelaunayTriangulationTraits_3::Tetrahedron_3` A tetrahedron type. It must be a model of `Kernel::Tetrahedron_3`.

`Periodic_3DelaunayTriangulationTraits_3::Compare_xyz_3`

A predicate object that must provide the function operators
`Comparison_result operator()(Point_3 p, Point_3 q),`
 which returns `EQUAL` if the two points are equal and
`Comparison_result operator()(Point_3 p, Point_3 q, Periodic_3_offset_3 o_p, Periodic_3_offset_3 o_q),`
 which returns `EQUAL` if the two point-offset pairs are equal. Otherwise it must return a consistent order for any two points chosen in a same line.
Precondition: p, q lie inside the domain.

Periodic_3DelaunayTriangulationTraits_3:: Orientation_3

A predicate object that must provide the function operators
Orientation operator()(Point_3 p, Point_3 q, Point_3 r, Point_3 s),
which returns *POSITIVE*, if *s* lies on the positive side of the oriented plane *h* defined by *p*, *q*, and *r*, returns *NEGATIVE* if *s* lies on the negative side of *h*, and returns *COPLANAR* if *s* lies on *h* and
Orientation operator()(Point_3 p, Point_3 q, Point_3 r, Point_3 s, Periodic_3_offset_3 o_p, Periodic_3_offset_3 o_q, Periodic_3_offset_3 o_r, Periodic_3_offset_3 o_s),
which returns *POSITIVE*, if the point-offset pair (*s,o_s*) lies on the positive side of the oriented plane *h* defined by (*p,o_p*), (*q,o_q*), and (*r,o_r*), returns *NEGATIVE* if (*s,o_s*) lies on the negative side of *h*, and returns *COPLANAR* if (*s,o_s*) lies on *h*.
Precondition: p, q, r, s lie inside the domain.

Periodic_3DelaunayTriangulationTraits_3:: Side_of_oriented_sphere_3

A predicate object that must provide the function operators
Oriented_side operator()(Point_3 p, Point_3 q, Point_3 r, Point_3 s, Point_3 t),
which determines on which side of the oriented sphere circumscribing *p, q, r, s* the point *t* lies and
Oriented_side operator()(Point_3 p, Point_3 q, Point_3 r, Point_3 s, Point_3 t, Periodic_3_offset_3 o_p, Periodic_3_offset_3 o_q, Periodic_3_offset_3 o_r, Periodic_3_offset_3 o_s, Periodic_3_offset_3 o_t),
which determines on which side of the oriented sphere circumscribing (*p,o_p*), (*q,o_q*), (*r,o_r*), (*s,o_s*) the point-offset pair (*t,o_t*) lies.
Precondition: p, q, r, s, t lie inside the domain.

Periodic_3DelaunayTriangulationTraits_3:: Compare_distance_3

A predicate object that must provide the function operators
Comparison_result operator()(Point_3 p, Point_3 q, Point_3 r),
which compares the distance between *p* and *q* to the distance between *p* and *r* and
Comparison_result operator()(Point_3 p, Point_3 q, Point_3 r, Periodic_3_offset_3 o_p, Periodic_3_offset_3 o_q, Periodic_3_offset_3 o_r),
which compares the distance between (*p,o_p*) and (*q,o_q*) to the distance between (*p,o_p*) and (*r,o_r*).
Precondition: p, q, r lie inside the domain.

In addition, only when vertex removal is used, the traits class must provide the following predicate objects:
Periodic_3DelaunayTriangulationTraits_3:: Coplanar_orientation_3

A predicate object that must provide the function operators
Oriented operator()(Point_3 p, Point_3 q, Point_3 r),
which returns *COLLINEAR*, if the points are collinear; otherwise it must return a consistent orientation for any three points chosen in a same plane and
Oriented operator()(Point_3 p, Point_3 q, Point_3 r, Periodic_3_offset_3 o_p, Periodic_3_offset_3 o_q, Periodic_3_offset_3 o_r),
which returns *COLLINEAR*, if the point-offset pairs are collinear; otherwise it must return a consistent orientation for any three point-offset pairs chosen in a same plane.
Precondition: p, q, r lie inside the domain.

Periodic_3DelaunayTriangulationTraits_3:: Coplanar_side_of_bounded_circle_3

A predicate object that must provide the function operators

Bounded_side operator()(Point_3 p, Point_3 q, Point_3 r, Point_3 s),

which determines the bounded side of the circle defined by p , q , and r on which the point s lies and

Bounded_side operator()(Point_3 p, Point_3 q, Point_3 r, Point_3 s, Periodic_3_offset_3 o_p, Periodic_3_offset_3 o_q, Periodic_3_offset_3 o_r, Periodic_3_offset_3 o_s),

which determines the bounded side of the circle defined by (p, o_p) , (q, o_q) , and (r, o_r) on which the point-offset pair (s, o_s) lies.

Precondition: p, q, r , and s are coplanar and p, q , and r are not collinear, $(p, o_p), (q, o_q), (r, o_r)$, and (s, o_s) are coplanar and $(p, o_p), (q, o_q)$, and (r, o_r) are not collinear, respectively, and p, q, r, s, t lie inside the domain.

In addition, only when *is_Gabriel* is used, the traits class must provide the following predicate object:
Periodic_3DelaunayTriangulationTraits_3:: Side_of_bounded_sphere_3

A predicate object that must provide the function operators

Bounded_side operator()(Point_3 p, Point_3 q, Point_3 t),

which returns the position of the point t relative to the sphere that has pq as its diameter,

Bounded_side operator()(Point_3 p, Point_3 q, Point_3 t, Periodic_3_offset_3 o_p, Periodic_3_offset_3 o_q, Periodic_3_offset_3 o_t),

which returns the position of the point-offset pair (t, o_t) relative to the sphere that has $(p, o_p)(q, o_q)$ as its diameter,

Bounded_side operator()(Point_3 p, Point_3 q, Point_3 r, Point_3 t),

which returns the position of the point t relative to the sphere passing through p , q , and r and whose center is in the plane defined by these three points,

Bounded_side operator()(Point_3 p, Point_3 q, Point_3 r, Point_3 t, Periodic_3_offset_3 o_p, Periodic_3_offset_3 o_q, Periodic_3_offset_3 o_r, Periodic_3_offset_3 o_t),

which returns the position of the point-offset pair (t, o_t) relative to the sphere passing through (p, o_p) , (q, o_q) , and (r, o_r) and whose center is in the plane defined by these three point-offset pairs,

Bounded_side operator()(Point_3 p, Point_3 q, Point_3 r, Point_3 s, Point_3 t),

which returns the relative position of point t to the sphere defined by p , q , r , and s ; the order of the points p , q , r , and s does not matter, and

Bounded_side operator()(Point_3 p, Point_3 q, Point_3 r, Point_3 s, Point_3 t, Periodic_3_offset_3 o_p, Periodic_3_offset_3 o_q, Periodic_3_offset_3 o_r, Periodic_3_offset_3 o_s, Periodic_3_offset_3 o_t),

which returns the relative position of the point-offset pair (t, o_t) to the sphere defined by (p, o_p) , (q, o_q) , (r, o_r) , and (s, o_s) ; the order of the point-offset pairs (p, o_p) , (q, o_q) , (r, o_r) , and (s, o_s) does not matter.

Precondition: p, q, r , and s are not coplanar, (p, o_p) , (q, o_q) , (r, o_r) , and (s, o_s) are not coplanar, p, q, r, s, t lie inside the domain.

Note that the traits must provide exact constructions in order to guarantee exactness of the following construction functors.

Periodic_3DelaunayTriangulationTraits_3:: Construct_point_3

A constructor object that must provide the function operator

Point_3 operator()(Point_3 p, Periodic_3_offset_3 o_p),

which constructs a point from a point-offset pair.

Precondition: p lies inside the domain.

Periodic_3DelaunayTriangulationTraits_3:: Construct_segment_3

A constructor object that must provide the function operators
Segment_3 operator()(Point_3 p, Point_3 q),
which constructs a segment from two points and
Segment_3 operator()(Point_3 p, Point_3 q, Periodic_3_offset_3 o_p, Periodic_3_offset_3 o_q),
which constructs a segment from two point-offset pairs.
Precondition: p, q lie inside the domain.

Periodic_3DelaunayTriangulationTraits_3:: Construct_triangle_3

A constructor object that must provide the function operators
Triangle_3 operator()(Point_3 p, Point_3 q, Point_3 r),
which constructs a triangle from three points and
Triangle_3 operator()(Point_3 p, Point_3 q, Point_3 r, Periodic_3_offset_3 o_q, Periodic_3_offset_3 o_r),
which constructs a triangle from three point-offset pairs.
Precondition: p, q, r lie inside the domain.

Periodic_3DelaunayTriangulationTraits_3:: Construct_tetrahedron_3

A constructor object that must provide the function operators
Tetrahedron_3 operator()(Point_3 p, Point_3 q, Point_3 r, Point_3 s),
which constructs a tetrahedron from four points and
Tetrahedron_3 operator()(Point_3 p, Point_3 q, Point_3 r, Point_3 s, Periodic_3_offset_3 o_q, Periodic_3_offset_3 o_r, Periodic_3_offset_3 o_s),
which constructs a tetrahedron from four point-offset pairs.
Precondition: p, q, r, s lie inside the domain.

In addition, only when the dual operations are used, the traits class must provide the following constructor object:

Periodic_3DelaunayTriangulationTraits_3:: Construct_circumcenter_3

A constructor object that must provide the function operators
Point_3 operator()(Point_3 p, Point_3 q, Point_3 r, Point_3 s),
which constructs the circumcenter of four points and
Point_3 operator()(Point_3 p, Point_3 q, Point_3 r, Point_3 s, Periodic_3_offset_3 o_p, Periodic_3_offset_3 o_q, Periodic_3_offset_3 o_r, Periodic_3_offset_3 o_s),
which constructs the circumcenter of four point-offset pairs.
Precondition: p, q, r and s as well as (p,o_p), (q,o_q), (r,o_r) and (s,o_s) must be non coplanar. p, q, r, s lie inside the domain.

The optional types must be provided in any case, however they can be replaced by dummy types if the respective functions are not used.

Creation

Periodic_3DelaunayTriangulationTraits_3 traits; Default constructor.
Periodic_3DelaunayTriangulationTraits_3 traits(Periodic_triangulation_traits_3 tr);

Copy constructor.

Access Functions

`void traits.set_domain(Iso_cuboid_3 domain)`

Set the size of the fundamental domain. This is necessary to evaluate predicates correctly.

Precondition: *domain* represents a cube.

Operations

The following functions give access to the predicate and construction objects:

`Compare_xyz_3` `traits.compare_xyz_3_object()`

`Orientation_3` `traits.orientation_3_object()`

`Side_of_oriented_sphere_3` `traits.side_of_oriented_sphere_3_object()`

`Compare_distance_3` `traits.compare_distance_3_object()`

The following functions must be provided if vertex removal is used; otherwise dummy functions can be provided.

`Coplanar_orientation_3` `traits.coplanar_3_orientation_3_object()`

`Coplanar_side_of_bounded_circle_3` `traits.coplanar_side_of_bounded_circle_3_object()`

The following function must be provided only if the *is_Gabriel* methods of *Periodic_3_Delaunay_triangulation_3* are used; otherwise a dummy function can be provided.

`Side_of_bounded_sphere_3` `traits.side_of_bounded_sphere_3_object()`

`Construct_segment_3` `traits.construct_segment_3_object()`

`Construct_triangle_3` `traits.construct_triangle_3_object()`

`Construct_tetrahedron_3` `traits.construct_tetrahedron_3_object()`

The following function must be provided only if the methods of *Periodic_3_Delaunay_triangulation_3* returning elements of the Voronoi diagram are used; otherwise a dummy function can be provided:

`Construct_circumcenter_3` `traits.construct_circumcenter_3_object()`

CGAL::Periodic_3_triangulation_traits_3<Traits,Periodic_3Offset_3>

Definition

The class *Periodic_3_triangulation_traits_3*<*Traits*,*Periodic_3Offset_3*> is designed as a default traits class for the class *Periodic_3_triangulation_3*<*Periodic_3TriangulationTraits_3*,*TriangulationDataStructure_3*>.

The argument *Traits* must be a model of the *DelaunayTriangulationTraits_3* concept. The argument *Periodic_3Offset_3* must be a model of the concept *Periodic_3Offset_3* and defaults to *Periodic_3_offset_3*.

Note that this template class is specialized for *CGAL::Filtered_kernel*, so that it automatically provides filtered predicates. This holds implicitly for *CGAL::Exact_predicates_inexact_constructions_kernel*, as it is an instantiation of *CGAL::Filtered_kernel*.

```
#include <CGAL/Periodic_3_triangulation_traits_3.h>
```

Is Model for the Concepts

Periodic_3DelaunayTriangulationTraits_3

Inherits From

Traits

Periodic_3TriangulationDSCellBase_3

Definition

At the base level (see Sections [39.5](#) and [38.2](#)), a cell stores handles to its four vertices and to its four neighbor cells. The vertices and neighbors are indexed 0, 1, 2 and 3. Neighbor i lies opposite to vertex i .

Refines

TriangulationDSCellBase_3

For periodic triangulation the cell base class needs to additionally store an offset for each vertex. Only the last three bits of each integer are required to be stored. The remaining part does not contain any information.

Access Functions

int *c.offset(int i)* Returns the offset of vertex i .
Precondition: $i \in \{0, 1, 2, 3\}$.

Setting

void *c.set_offsets(int off0, int off1, int off2, int off3)*
 Sets the vertex offsets according to *off0* to *off3*.

Periodic_3TriangulationDSVertexBase_3

Definition

At the base level of 3D-triangulations (see Sections 39.5 and 38.2), a vertex provides access to one of its incident cells through a handle.

For optimization purposes we need to extend the concept *TriangulationDSVertexBase_3* as follows.

Refines

TriangulationDSVertexBase_3

Periodic_3TriangulationDSVertexBase_3 needs to store an offset and some index inside the vertex.

Types

Periodic_3TriangulationDSVertexBase_3::Periodic_3_offset_3 A model of the concept *Periodic_3Offset_3*

Access Functions

<i>Periodic_3_offset_3</i>	<i>v.offset()</i>	Returns the offset stored in the vertex.
<i>bool</i>	<i>v.get_offset_flag()</i>	Returns <i>true</i> if the offset has been set, <i>false</i> otherwise.
<i>void</i>	<i>v.set_offset(Periodic_3_offset_3 o)</i>	Sets the offset and sets the offset flag to <i>true</i> .
<i>void</i>	<i>v.clear_offset()</i>	Sets the offset flag to <i>false</i> and clears the offset.

Periodic_3Offset_3

Definition

The concept `Periodic_3Offset_3` describes a three-dimensional integer vector with some specialized access functions and operations.

Creation

<code>Periodic_3Offset_3 o;</code>	Default constructor.
<code>Periodic_3Offset_3 o(int x, int y, int z);</code>	Constructs the offset (x,y,z).

Operations

<code>Periodic_3Offset_3</code>	<code>o + o'</code>	Return the vector sum of o and o' .
<code>Periodic_3Offset_3</code>	<code>o - o'</code>	Return the vector difference of o and o' .
<code>Periodic_3Offset_3</code>	<code>-o</code>	Return the negative vector of o .
<code>void</code>	<code>o += o'</code>	Add o' to o using vector addition.
<code>void</code>	<code>o -= o'</code>	Subtract o' from o using vector subtraction.
<code>bool</code>	<code>o == o'</code>	Return <i>true</i> if o' and o represent the same vector.
<code>bool</code>	<code>o != o'</code>	Return <i>true</i> if o' and o do not represent the same vector.
<code>bool</code>	<code>o < o'</code>	Compare o and o' lexicographically.

Access Functions

<code>int</code>	<code>o[int i]</code>	Return the i -th entry of o .
<code>int</code>	<code>o.x()</code>	Return the x -entry of o .
<code>int</code>	<code>o.y()</code>	Return the y -entry of o .
<code>int</code>	<code>o.z()</code>	Return the z -entry of o .
<code>bool</code>	<code>o.is_null()</code>	Returns <i>true</i> if o is equal to (0,0,0).

I/O

<code>istream&</code>	<code>istream & is >> Periodic_3_offset_3 & off</code>	Inputs an offset from is .
<code>ostream&</code>	<code>ostream & os << Periodic_3_offset_3 & off</code>	Outputs an offset from os .

```

Is Model for the Concepts

Periodic_3Offset_3

CGAL::Periodic_3_triangulation_3::Iterator_type

Definition

The enum *Iterator_type* is defined by *Periodic_3_triangulation_3* to specify the behavior of geometric iterators.

```
enum Iterator_type { STORED=0, UNIQUE, STORED_COVER_DOMAIN, UNIQUE_COVER_DOMAIN};
```

The elements of the enum have the following meaning:

- **STORED**: Return all geometric primitives as they are stored internally in *Triangulation_data_structure_3*.
- **UNIQUE**: Return only one representative of each geometric primitive even if the triangulation is computed in a multiply sheeted covering space. Choose the representative whose maximum offset is minimal but non-negative in each direction of space.
- **STORED_COVER_DOMAIN**: Same as **STORED** but return additionally all primitives whose intersection with the original domain of the current covering space is non-empty.
- **UNIQUE_COVER_DOMAIN**: Same as **UNIQUE** but return additionally all primitives whose intersection with the original domain is non-empty.

Assume we are given a set S of points in 2D or 3D and we'd like to have something like “the shape formed by these points.” This is quite a vague notion and there are probably many possible interpretations, the α -shape

being one of them. Alpha shapes can be used for shape reconstruction from a dense unorganized set of data points. Indeed, an α -shape is demarcated by a frontier, which is a linear approximation of the original shape [BB97].

As mentioned in Edelsbrunner’s and Mücke’s paper [EM94], one can intuitively think of an α -shape as the following. Imagine a huge mass of ice-cream making up the space \mathbb{R}^3 and containing the points as “hard” chocolate pieces. Using one of these sphere-formed ice-cream spoons we carve out all parts of the ice-cream block we can reach without bumping into chocolate pieces, thereby even carving out holes in the inside (e.g. parts not reachable by simply moving the spoon from the outside). We will eventually end up with a (not necessarily convex) object bounded by caps, arcs and points. If we now straighten all “round” faces to triangles and line segments, we have an intuitive description of what is called the α -shape of S . Here’s an example for this process in 2D (where our ice-cream spoon is simply a circle):

And what is α in the game? α is the squared radius of the carving spoon. A very small value will allow us to eat up all of the ice-cream except the chocolate points themselves. Thus we already see that the α -shape degenerates to the point-set S for $\alpha \rightarrow 0$. On the other hand, a huge value of α will prevent us even from moving the spoon between two points since it’s way too large. So we will never spoon up ice-cream lying in the inside of the convex hull of S , and hence the α -shape for $\alpha \rightarrow \infty$ is the convex hull of S .¹

40.1 Definitions

We distinguish two versions of alpha shapes. *Basic alpha shapes* are based on the Delaunay triangulation. *Weighted alpha shapes* are based on its generalization, the regular triangulation, replacing the euclidean distance by the power to weighted points.

There is a close connection between alpha shapes and the underlying triangulations. More precisely, the α -complex of S is a subcomplex of this triangulation of S , containing the α -exposed k -simplices, $0 \leq k \leq d$. A simplex is α -exposed, if there is an open disk (resp. ball) of radius $\sqrt{\alpha}$ through the vertices of the simplex that does not contain any other point of S , for the metric used in the computation of the underlying triangulation. The corresponding α -shape is defined as the underlying interior space of the α -complex (see [EM94]).

In general, an α -complex is a non-connected and non-pure polytope, it means, that one k -simplex, $0 \leq k \leq d - 1$ is not necessary adjacent to a $(k + 1)$ -simplex.

The α -shapes of S form a discrete family, even though they are defined for all real numbers α with $0 \leq \alpha \leq \infty$. Thus, we can represent the entire family of α -shapes of S by the underlying triangulation of S . In this representation each k -simplex of the underlying triangulation is associated with an interval that specifies for which values of α the k -simplex belongs to the α -shape. Relying on this fact, the family of α -shapes can be computed efficiently and relatively easily. Furthermore, we can select an appropriate α -shape from a finite number of different α -shapes and corresponding α -values.

40.2 Functionality

The class `CGAL::Alpha_shape_2<Dt>` represents the family of α -shapes of points in a plane for *all* positive α . It maintains the underlying triangulation Dt which represents connectivity and order among squared radius of its faces. Each k -dimensional face of the Dt is associated with an interval that specifies for which values of

¹ice cream, ice cream!!! The wording of this introductory paragraphs is borrowed from Kaspar Fischer’s “Introduction to Alpha Shapes” which can be found at <http://people.inf.ethz.ch/fischerk/pubs/as.pdf>. The picture has been taken from Walter Luh’s homepage at <http://www.stanford.edu/~wluh/cs448b/alphashapes.html>.

α the face belongs to the α -shape. There are links between the intervals and the k -dimensional faces of the triangulation.

The class `CGAL::Alpha_shape_2<Dt>` provides functions to set and get the current α -value, as well as an iterator that enumerates the α -values where the α -shape changes.

It provides iterators to enumerate the vertices and edges that are in the α -shape, and functions that allow to classify vertices, edges and faces with respect to the α -shape. They can be in the interior of a face that belongs or does not belong to the α -shape. They can be singular/regular, that is be on the boundary of the α -shape, but not incident/incident to a triangle of the α -complex.

Finally, it provides a function to determine the α -value such that the α -shape satisfies the following two properties, or at least the second one if there is no such α that both are satisfied:

- (i) The number of components equals a number of your choice and
- (ii) all data points are either on the boundary or in the interior of the regularized version of the α -shape (no singular edges).

The current implementation is static, that is after its construction points cannot be inserted or removed.

40.3 Concepts and Models

We currently do not specify concepts for the underlying triangulation type. Models that work for a basic alpha-shape are the classes `CGAL::Delaunay_triangulation_2` and `CGAL::Triangulation_hierarchy_2` templated with a Delaunay triangulation. A model that works for a weighted alpha-shape is the class `CGAL::Regular_triangulation_2`.

The triangulation needs a geometric traits class as argument. The requirements of this class are described in the concept `CGAL::AlphaShapeTraits_2` for which the CGAL kernels and `CGAL::Weighted_alpha_shape_euclidean_traits_2` are models.

There are no requirements on the triangulation data structure. However it must be parameterized with vertex and face classes, which are model of the concepts `AlphaShapeVertex_2` and `AlphaShapeFace_2`, by default the classes `CGAL::Alpha_shape_vertex_base_2<Gt>` and `CGAL::Alpha_shape_face_base_2<Tf>`.

40.4 Examples

40.4.1 Example for Basic Alpha-Shapes

The basic alpha shape needs a Delaunay triangulation as underlying triangulation Dt . The Delaunay triangulation class is parameterized with a geometric and a triangulation data structure traits.

For the geometric traits class we can use a CGAL kernel.

For the triangulation data structure traits, we have to choose the vertex and face classes needed for alpha shapes, namely `CGAL::Alpha_shape_vertex_base_2<Gt, Dv>` and `CGAL::Alpha_shape_face_base_2<Gt, Df>`. As default vertex and face type they use `CGAL::Triangulation_vertex_base_2<Gt>` and `CGAL::Triangulation_face_base_2<Gt>` respectively.

The following code snippet shows how to obtain a basic alpha shape type.

```

typedef CGAL::Exact_predicates_inexact_constructions_kernel K;

typedef CGAL::Alpha_shape_vertex_base_2<K> Av;

typedef CGAL::Triangulation_face_base_2<K> Tf;
typedef CGAL::Alpha_shape_face_base_2<K,Tf> Af;

typedef CGAL::Triangulation_default_data_structure_2<K,Av,Af> Tds;
typedef CGAL::Delaunay_triangulation_2<K,Tds> Dt;
typedef CGAL::Alpha_shape_2<Dt> Alpha_shape_2;

```

40.4.2 Example for Basic Alpha-Shapes with Many Points

When the input data set is huge, say more than 10.000 points, it pays off to use a triangulation hierarchy. It has the same API as the Delaunay triangulation and differs only in the types of the vertices and faces. Therefore, the only part that changes are the typedefs in the beginning.

```

typedef CGAL::Exact_predicates_inexact_constructions_kernel K;

typedef CGAL::Alpha_shape_vertex_base_2<K> Avb;
typedef CGAL::Triangulation_hierarchy_vertex_base_2<Avb> Av

typedef CGAL::Triangulation_face_base_2<K> Tf;
typedef CGAL::Alpha_shape_face_base_2<K,Tf> Af;

typedef CGAL::Triangulation_default_data_structure_2<K,Av,Af> Tds;
typedef CGAL::Delaunay_triangulation_2<K,Tds> Dt;
typedef CGAL::Triangulation_hierarchy_2<Dt> Ht;
typedef CGAL::Alpha_shape_2<Ht> Alpha_shape_2;

```

40.4.3 Example for Weighted Alpha-Shapes

A weighted alpha shape, needs a regular triangulation as underlying triangulation *Dt*, and it needs a particular face class, namely *CGAL::Regular_triangulation_face_base_2<Gt>*. Note that there is no special weighted alpha shape class.

```

typedef CGAL::Exact_predicates_inexact_constructions_kernel K;
typedef CGAL::Weighted_alpha_shape_euclidean_traits_2<K> Gt;

typedef CGAL::Alpha_shape_vertex_base_2<Gt> Av;

typedef CGAL::Regular_triangulation_face_base_2<Gt> Rf;
typedef CGAL::Alpha_shape_face_base_2<Gt,Rf> Af;

typedef CGAL::Triangulation_default_data_structure_2<Gt,Av,Af> Tds;
typedef CGAL::Regular_triangulation_2<Gt,Tds> Rt;
typedef CGAL::Alpha_shape_2<Rt> Alpha_shape_2;

```

2D Alpha Shapes

Reference Manual

Tran Kai Frank Da

This chapter presents a framework for alpha shapes. The description is based on the articles [EM94, Ede92]. Alpha shapes are the generalization of the convex hull of a point set. Let S be a finite set of points in \mathbb{R}^d , $d = 2, 3$ and α a parameter with $0 \leq \alpha \leq \infty$. For $\alpha = \infty$, the α -shape is the convex hull of S . As α decreases, the α -shape shrinks and develops cavities, as soon as a sphere of radius $\sqrt{\alpha}$ can be put inside. Finally, for $\alpha = 0$, the α -shape is the set S itself.

We distinguish two versions of alpha shapes, one is based on the Delaunay triangulation and the other on its generalization, the regular triangulation, replacing the natural distance by the power to weighted points. The metric used determines an underlying triangulation of the alpha shape and thus, the version computed. The *basic alpha shape* (cf. 40.4.1) is associated with the Delaunay triangulation (cf. 35.5). The *weighted alpha shape* (cf. 40.4.3) is associated with the regular triangulation (cf. 35.6).

There is a close connection between alpha shapes and the underlying triangulations. More precisely, the α -complex of S is a subcomplex of this triangulation of S , containing the α -exposed k -simplices, $0 \leq k \leq d$. A simplex is α -exposed, if there is an open disk (resp. ball) of radius $\sqrt{\alpha}$ through the vertices of the simplex that does not contain any other point of S , for the metric used in the computation of the underlying triangulation. The corresponding α -shape is defined as the underlying interior space of the α -complex.

In general, an α -complex is a non-connected and non-pure polytope, it means, that one k -simplex, $0 \leq k \leq d - 1$ is not necessary adjacent to a $(k + 1)$ -simplex.

The α -shapes of S form a discrete family, even though they are defined for all real numbers α with $0 \leq \alpha \leq \infty$. Thus, we can represent the entire family of α -shapes of S by the underlying triangulation of S . In this representation each k -simplex of the underlying triangulation is associated with an interval that specifies for which values of α the k -simplex belongs to the α -shape. Relying on this result, the family of α -shapes can be computed efficiently and relatively easily. Furthermore, we can select an appropriate α -shape from a finite number of different α -shapes and corresponding α -values.

CGAL::Alpha_shape_2<Dt>

Definition

The class *Alpha_shape_2<Dt>* represents the family of α -shapes of points in a plane for *all* positive α . It maintains the underlying triangulation *Dt* which represents connectivity and order among its faces. Each *k*-dimensional face of the *Dt* is associated with an interval that specifies for which values of α the face belongs to the α -shape. There are links between the intervals and the *k*-dimensional faces of the triangulation.

Note that this class is at the same time used for *basic* and for *weighted* Alpha Shapes.

```
#include <CGAL/Alpha_shape_2.h>
```

Inherits From

Dt

This class is the underlying triangulation class.

The modifying functions *insert* and *remove* will overwrite the inherited functions. At the moment, only the static version is implemented.

Types

Alpha_shape_2<Dt>:: Gt the alpha shape traits type.

it has to derive from a triangulation traits class. For example *Dt::Point* is a Point class.

```
typedef Gt::FT
```

FT; the number type for computation.

Alpha_shape_2<Dt>:: size_type The size type.

Alpha_shape_2<Dt>:: Alpha_iterator

A bidirectional and non-mutable iterator that allow to traverse the increasing sequence of different α -values.
Precondition: Its *value_type* is *FT*

Alpha_shape_2<Dt>:: Alpha_shape_vertices_iterator

A bidirectional and non-mutable iterator that allow to traverse the vertices which belongs to the α -shape for the current α .
Precondition: Its *value_type* is *Dt::Vertex_handle*

Alpha_shape_2<Dt>:: Alpha_shape_edges_iterator

A bidirectional and non-mutable iterator that allow to traverse the edges which belongs to the α -shape for the current α .
Precondition: Its *value_type* is *Dt::Edge*.

enum Classification_type { EXTERIOR, SINGULAR, REGULAR, INTERIOR};

Distinguishes the different cases for classifying a k -dimensional face of the underlying triangulation of the α -shape.

EXTERIOR if the face does not belong to the α -complex.

SINGULAR if the face belongs to the boundary of the α -shape, but is not incident to any 2-dimensional face of the α -complex

REGULAR if the face belongs to the boundary of the α -shape and is incident to a 2-dimensional face of the α -complex

INTERIOR if the face belongs to the α -complex, but does not belong to the boundary of the α -shape.

enum Mode { GENERAL, REGULARIZED};

In general, an alpha shape can be disconnected and contain many singular edges or vertices. Its regularized version is formed by the set of regular edges and their vertices.

Creation

Alpha_shape_2<Dt> A(FT alpha = 0, Mode m = GENERAL);

Introduces an empty α -shape A for a positive α -value $alpha$.

Precondition: $alpha \geq 0$.

template < class InputIterator >

Alpha_shape_2<Dt> A(InputIterator first, InputIterator last, FT alpha = 0, Mode m = GENERAL);

Initializes the family of alpha-shapes with the points in the range $[first, last)$ and introduces an α -shape A for a positive α -value $alpha$.

Precondition: The *value_type* of *first* and *last* is *Point*.
 $alpha \geq 0$.

Operations

template < class InputIterator >

std::ptrdiff_t A.make_alpha_shape(InputIterator first, InputIterator last)

Initialize the family of alpha-shapes with the points in the range $[first, last)$. Returns the number of inserted points.

If the function is applied to a non-empty family of alpha-shape, it is cleared before initialization.

Precondition: The *value_type* of *first* and *last* is *Point*.

void A.clear() Clears the structure.

<i>FT</i>	<i>A.set_alpha(FT alpha)</i>	
		Sets the α -value to <i>alpha</i> . Returns the previous α -value. <i>Precondition: alpha</i> \geq 0.
<i>FT</i>	<i>A.get_alpha(void)</i>	Returns the current α -value.
<i>FT</i>	<i>A.get_nth_alpha(size_type n)</i>	
		Returns the <i>n</i> -th alpha-value, sorted in an increasing order. <i>Precondition: n</i> < number of alphas.
<i>size_type</i>	<i>A.number_of_alphas()</i>	
		Returns the number of different alpha-values.
<i>Mode</i>	<i>A.set_mode(Mode m = GENERAL)</i>	
		Sets <i>A</i> to its general or regularized version. Returns the previous mode.
<i>Mode</i>	<i>A.get_mode(void)</i>	Returns whether <i>A</i> is general or regularized.
<i>Alpha_shape_vertices_iterator</i>		
	<i>A.alpha_shape_vertices_begin()</i>	
		Starts at an arbitrary finite vertex which belongs to the α -shape for the current α .
<i>Alpha_shape_vertices_iterator</i>		
	<i>A.alpha_shape_vertices_end()</i>	
		Past-the-end iterator.
<i>Alpha_shape_edges_iterator</i>		
	<i>A.alpha_shape_edges_begin()</i>	
		Starts at an arbitrary finite edge which belongs to the α -shape for the current α . In regularized mode, edges are represented as a pair (f,i), where f is an interior face of the α -shape.
<i>Alpha_shape_edges_iterator</i>		
	<i>A.alpha_shape_edges_end()</i>	
		Past-the-end iterator.

Predicates

Classification_type

A.classify(Point p, FT alpha = get_alpha())

Locates a point p in the underlying triangulation and Classifies the associated k -face with respect to A .

Classification_type

A.classify(Face_handle f, FT alpha = get_alpha())

Classifies the face f of the underlying triangulation with respect to A .

Classification_type

A.classify(Edge e, FT alpha = get_alpha())

Classifies the edge e of the underlying triangulation with respect to A .

Classification_type

A.classify(Face_handle f, int i, FT alpha = get_alpha())

Classifies the edge of the face f opposite to the vertex with index i of the underlying triangulation with respect to A .

Classification_type

A.classify(Vertex_handle v, FT alpha = get_alpha())

Classifies the vertex v of the underlying triangulation with respect to A .

Traversal of the α -Values

Alpha_iterator

A.alpha_begin() Returns an iterator that allows to traverse the sorted sequence of α -values of the family of alpha shapes.

Alpha_iterator

A.alpha_end() Returns the corresponding past-the-end iterator.

Alpha_iterator

A.alpha_find(FT alpha)

Returns an iterator pointing to an element with α -value $alpha$, or the corresponding past-the-end iterator if such an element is not found.

Alpha_iterator

A.alpha_lower_bound(FT alpha)

Returns an iterator pointing to the first element with α -value not less than *alpha*.

Alpha_iterator

A.alpha_upper_bound(FT alpha)

Returns an iterator pointing to the first element with α -value greater than *alpha*.

Operations

size_type *A.number_of_solid_components(FT alpha = get_alpha())*

Returns the number of solid components of *A*, that is, the number of components of its regularized version.

Alpha_iterator

A.find_optimal_alpha(size_type nb_components)

Returns an iterator pointing to the first element with α -value such that *A* satisfies the following two properties:

nb_components equals the number of solid components and all data points are either on the boundary or in the interior of the regularized version of *A*.

If no such value is found, the iterator points to the first element with α -value such that *A* satisfies the second property.

I/O

The I/O operators are defined for *iostream*. The format for the *iostream* is an internal format.

#include <CGAL/IO/io.h>

ostream& *ostream& os << A* Inserts the alpha shape *A* for the current α -value into the stream *os*.
Precondition: The insert operator must be defined for *Point*.

Implementation

The set of intervals associated with the *k*-dimensional faces of the underlying triangulation are stored in *multimaps*.

The cross links between the intervals and the *k*-dimensional faces of the triangulation are realized using methods in the *k*-dimensional faces themselves.

A.alpha find uses linear search, while *A.alpha lower bound* and *A.alpha upper bound* use binary search. *A.number of solid components* performs a graph traversal and takes time linear in the number of faces of the underlying triangulation. *A.find optimal alpha* uses binary search and takes time $O(n \log n)$, where n is the number of points.

AlphaShapeFace_2

Definition

Refines

TriangulationFaceBase_2.

Types

AlphaShapeFace_2:: Interval_3

A container type to get (and put) the three special values $(\alpha_1, \alpha_2, \alpha_3)$ associated with an alpha shape edge.

AlphaShapeFace_2:: FT

A type to hold a coordinate type class. The type must provide a copy constructor, assignment, comparison operators, negation, multiplication, division and allow the declaration and initialization with a small integer constant (cf. requirements for number types). An obvious choice would be coordinate type of the point class

Creation

advanced

AlphaShapeTraits_2

Definition

A model of the concept AlphaShapeTraits_2 must provide the following predicate and operations in addition to the requirements for the underlying triangulation traits class. It means, the metric has to be euclidean for Delaunay triangulation or the power metric for regular triangulation.

Refines

TriangulationTraits_2

Types

AlphaShapeTraits_2::FT

A type to hold a coordinate type class. The type must provide a copy constructor, assignment, comparison operators, negation, multiplication, division and allow the declaration and initialization with a small integer constant (cf. requirements for number types).

Precondition: An obvious choice would be coordinate type of the point class.

Creation

Only a default constructor is required. Note that further constructors can be provided.

AlphaShapeTraits_2 t;

A default constructor.

Constructions by function objects

Compute_squared_radius_2

t.compute_squared_radius_2_object()

Returns an object, which has to be able to compute the squared radius of the circle of the points p_0 , p_1 , p_2 or the squared radius of smallest circle of the points p_0 , p_1 , as *FT* associated with *the metric used by Dt*.

Predicate by function object

Side_of_bounded_circle_2

t.side_of_bounded_circle_2_object()

Returns an object, which has to be able to compute the relative position of point *test* to the smallest circle of the points p_0 , p_1 , using *the same metric as Dt*.

CGAL::Weighted_alpha_shape_euclidean_traits_2<K>

Definition

The class *Weighted_alpha_shape_euclidean_traits_2<K>* is the default model for the concept *AlphaShapeTraits_2* for the regular version of Alpha Shapes. *K* must be a kernel.

AlphaShapeVertex_2:: FT

A type to hold a coordinate type class. The type must provide a copy constructor, assignment, comparison operators, negation, multiplication, division and allow the declaration and initialization with a small integer constant (cf. requirements for number types). An obvious choice would be coordinate type of the point class.

Creation

— *advanced* —

```
AlphaShapeVertex_2 v;  
AlphaShapeVertex_2 v( Point p);  
AlphaShapeVertex_2 v( Point p, Face_handle ff);
```

default constructor.
constructor setting the point.

constructor setting the point associated to and an incident face.

— *advanced* —

Access Functions

std::pair< FT, FT > v.get_range()

returns two alpha values $\alpha_1 \leq \alpha_2$, such as for α between α_1 and α_2 , the vertex is attached but singular, and for α upper α_2 , the vertex is regular.

Modifiers

— *advanced* —

```
void v.set_range( std::pair< FT, FT > I)
```

sets the alpha values $\alpha_1 \leq \alpha_2$, such as for α between α_1 and α_2 , the vertex is attached but singular, and for α upper α_2 , the vertex is regular.

— *advanced* —

CGAL::Alpha_shape_vertex_base_2<AlphaShapeTraits_2>

Definition

The class *Alpha_shape_vertex_base_2<AlphaShapeTraits_2>* is the default model for the concept *AlphaShapeVertex_2*.

Assume we are given a set S of points in 2D or 3D and we'd like to have something like “the shape formed by these points.” This is quite a vague notion and there are probably many possible interpretations, the alpha shape being one of them. Alpha shapes can be used for shape reconstruction from a dense unorganized set of data points. Indeed, an alpha shape is demarcated by a frontier, which is a linear approximation of the original shape [BB97].

As mentioned in Edelsbrunner's and Mücke's paper [EM94], one can intuitively think of an alpha shape as the following. Imagine a huge mass of ice-cream making up the space \mathbb{R}^3 and containing the points as “hard” chocolate pieces. Using one of those sphere-formed ice-cream spoons we carve out all parts of the ice-cream block we can reach without bumping into chocolate pieces, thereby even carving out holes in the inside (e.g. parts not reachable by simply moving the spoon from the outside). We will eventually end up with a (not necessarily convex) object bounded by caps, arcs and points. If we now straighten all “round” faces to triangles and line segments, we have an intuitive description of what is called the alpha shape of S . Here's an example for this process in 2D (where our ice-cream spoon is simply a circle):

Alpha shapes depend on a parameter α from which they are named. What is α in the ice-cream game? α is the squared radius of the carving spoon. A very small value will allow us to eat up all of the ice-cream except the chocolate points themselves. Thus we already see that the alpha shape degenerates to the point-set S for $\alpha \rightarrow 0$. On the other hand, a huge value of α will prevent us even from moving the spoon between two points since it's way too large. So we will never spoon up ice-cream lying in the inside of the convex hull of S , and hence the alpha shape for $\alpha \rightarrow \infty$ is the convex hull of S .¹

41.1 Definitions

More precisely, the definition of alpha shapes is based on an underlying triangulation that may be a Delaunay triangulation in case of basic alpha shapes or a regular triangulation (cf. 37.3) in case of weighted alpha shapes.

Let us consider the basic case with a Delaunay triangulation. We first define the alpha complex of the set of points S . The alpha complex is a subcomplex of the Delaunay triangulation. For a given value of α , the alpha complex includes all the simplices in the Delaunay triangulation which have an empty circumsphere with squared radius equal or smaller than α . Here “empty” means that the open sphere does not include any points of S . The alpha shape is then simply the domain covered by the simplices of the alpha complex (see [EM94]).

In general, an alpha complex is a non-connected and non-pure complex. This means in particular that the alpha complex may have singular faces. For $0 \leq k \leq d - 1$, a k -simplex of the alpha complex is said to be singular if it is not a facet of a $(k + 1)$ -simplex of the complex. CGAL provides two versions of the alpha shapes. In the general mode, the alpha shapes correspond strictly to the above definition. The regularized mode provides a regularized version of the alpha shapes corresponding to the domain covered by a regularized version of the alpha complex where singular faces are removed.

The alpha shapes of a set of points S form a discrete family, even though they are defined for all real numbers α . The entire family of alpha shapes can be represented through the underlying triangulation of S . In this representation each k -simplex of the underlying triangulation is associated with an interval that specifies for which values of α the k -simplex belongs to the alpha complex. Relying on this fact, the family of alpha shapes can be computed efficiently and relatively easily. Furthermore, we can select the optimal value of α to get an alpha shape including all data points and having less than a given number of connected components. Also, the alpha-values allow to define a filtration on the faces of the triangulation of a set of points. In this filtration, the faces of the triangulation are output in increasing order of the alpha value for which they appear in the alpha complex. In case of equal alpha value lower dimensional faces are output first.

¹ice cream, ice cream!!! The wording of this introductory paragraph is borrowed from Kaspar Fischer's “Introduction to Alpha Shapes” which can be found at <http://people.inf.ethz.ch/fischerk/pubs/as.pdf>. The picture has been taken from Walter Luh's homepage at <http://www.stanford.edu/~luh/cs448b/alphashapes.html>.

The definition is analog in the case of weighted alpha shapes. The input set is now a set of weighted points (which can be regarded as spheres) and the underlying triangulation is the regular triangulation of this set. Two spheres, or two weighted points, with centers C_1, C_2 and radii r_1, r_2 are said to be orthogonal iff $C_1 C_2^2 = r_1^2 + r_2^2$ and suborthogonal iff $C_1 C_2^2 < r_1^2 + r_2^2$. For a given value of α the weighted alpha complex is formed with the simplices of the regular triangulation such that there is a sphere orthogonal to the weighted points associated with the vertices of the simplex and suborthogonal to all the other input weighted points. Once again the alpha shape is then defined as the domain covered by the alpha complex and arise in two versions general or regularized.

41.2 Functionality

The class `CGAL::Alpha_shape_3<Dt>` represents the whole family of alpha shapes for a given set of points. The class includes the underlying triangulation Dt of the set, and associates to each k -face of this triangulation an interval specifying for which values of α the face belongs to the alpha complex.

The class `CGAL::Alpha_shape_3<Dt>` provides functions to set and get the current α -value, as well as an iterator that enumerates the α values where the alpha shape changes.

The class provides member functions to classify for a given value of *alpha* the different faces of the triangulation as *EXTERIOR*, *SINGULAR*, *REGULAR* or *INTERIOR* with respect to the alpha shape. A k face on the boundary of the alpha complex is said to be *REGULAR* if it is a subface of the alpha complex which is a subface of some $k + 1$ face of the alpha complex and *SINGULAR* otherwise.

The class provides also output iterators to get for a given *alpha* value the vertices, edges, facets and cells of the different types (*EXTERIOR*, *SINGULAR*, *REGULAR* or *INTERIOR*).

Also the class has a filtration member function that, given an output iterator with `CGAL::object` as value type, outputs the faces of the triangulation according to the order of apparition in the alpha complex when alpha increases.

Finally, it provides a function to determine the smallest value α such that the alpha shape satisfies the following two properties

- (ii) all data points are either on the boundary or in the interior of the regularized version of the alpha shape (no singular faces).
- (i) The number of components is equal or less than a given number .

The current implementation is static, that is after its construction points cannot be inserted or removed.

41.3 Concepts and Models

We currently do not specify concepts for the underlying triangulation type. Models that work for a basic alpha-shape are the instantiations of the classes `CGAL::Delaunay_triangulation_3` and `CGAL::Periodic_3_Delaunay_triangulation_3` (see example 41.4.4). A model that works for a weighted alpha-shape is the class `CGAL::Regular_triangulation_3`.

The triangulation needs a geometric traits class as argument. The requirements of this class are described in the concept `CGAL::AlphaShapeTraits_3` for which the CGAL kernels are models in the non-weighted case, and for which the class `CGAL::Regular_triangulation_euclidean_traits_3` is model in the weighted case.

The triangulation data structure of the triangulation with any has to be a model of the concept `CGAL::TriangulationDataStructure_3`. However it must be parameterized with vertex and cell classes, which

are models of the concepts *AlphaShapeVertex_3* and *AlphaShapeCell_3*. The package provides by default the classes *CGAL::Alpha_shape_vertex_base_3<Gt>* and *CGAL::Alpha_shape_cell_base_3<Gt>*. When using *CGAL::Periodic_3_Delaunay_triangulation_3* as underlying triangulation the vertex and cell classes need to be models to both *AlphaShapeVertex_3* and *Periodic_3TriangulationDSVertexBase_3* as well as *AlphaShapeCell_3* and *Periodic_3TriangulationDSCellBase_3* (see example 41.4.4).

41.4 Examples

41.4.1 Example for Basic Alpha-Shapes

This example builds a basic alpha shape using a Delaunay triangulation as underlying triangulation.

```
#include <CGAL/Exact_predicates_inexact_constructions_kernel.h>
#include <CGAL/Delaunay_triangulation_3.h>
#include <CGAL/Alpha_shape_3.h>

#include <fstream>
#include <list>
#include <cassert>

typedef CGAL::Exact_predicates_inexact_constructions_kernel Gt;

typedef CGAL::Alpha_shape_vertex_base_3<Gt> Vb;
typedef CGAL::Alpha_shape_cell_base_3<Gt> Fb;
typedef CGAL::Triangulation_data_structure_3<Vb,Fb> Tds;
typedef CGAL::Delaunay_triangulation_3<Gt,Tds> Triangulation_3;
typedef CGAL::Alpha_shape_3<Triangulation_3> Alpha_shape_3;

typedef Gt::Point_3 Point;
typedef Alpha_shape_3::Alpha_iterator Alpha_iterator;

int main()
{
    std::list<Point> lp;

    //read input
    std::ifstream is("./data/bunny_1000");
    int n;
    is >> n;
    std::cout << "Reading " << n << " points " << std::endl;
    Point p;
    for( ; n>0 ; n--) {
        is >> p;
        lp.push_back(p);
    }

    // compute alpha shape
    Alpha_shape_3 as(lp.begin(),lp.end());
    std::cout << "Alpha shape computed in REGULARIZED mode by default"
               << std::endl;

    // find optimal alpha value
```

```

Alpha_iterator opt = as.find_optimal_alpha(1);
std::cout << "Optimal alpha value to get one connected component is "
           << *opt << std::endl;
as.set_alpha(*opt);
assert(as.number_of_solid_components() == 1);
return 0;
}

```

File: examples/Alpha_shapes_3/ex_alpha_shapes_3.cpp

41.4.2 Building Basic Alpha Shapes for Many Points

When many points are input in the alpha shape, say more than 10 000, it may pay off to use a Delaunay triangulation with *Fast_location* policy as underlying triangulation in order to speed up point location queries (cf. 37.4.3).

```

#include <CGAL/Exact_predicates_inexact_constructions_kernel.h>
#include <CGAL/Delaunay_triangulation_3.h>
#include <CGAL/Alpha_shape_3.h>

#include <fstream>
#include <list>
#include <cassert>

typedef CGAL::Exact_predicates_inexact_constructions_kernel K;

typedef CGAL::Alpha_shape_vertex_base_3<K> Vb;
typedef CGAL::Alpha_shape_cell_base_3<K> Fb;
typedef CGAL::Triangulation_data_structure_3<Vb,Fb> Tds;
typedef CGAL::Delaunay_triangulation_3<K,Tds,CGAL::Fast_location>
    Delaunay;
typedef CGAL::Alpha_shape_3<Delaunay> Alpha_shape_3;

typedef K::Point_3 Point;
typedef Alpha_shape_3::Alpha_iterator Alpha_iterator;
typedef Alpha_shape_3::NT NT;

int main()
{
    Delaunay dt;
    std::ifstream is("./data/bunny_1000");
    int n;
    is >> n;
    Point p;
    std::cout << n << " points read" << std::endl;
    for( ; n>0 ; n--) {
        is >> p;
        dt.insert(p);
    }
    std::cout << "Delaunay computed." << std::endl;

    // compute alpha shape

```

```

Alpha_shape_3 as(dt);
std::cout << "Alpha shape computed in REGULARIZED mode by default."
          << std::endl;

// find optimal alpha values
Alpha_shape_3::NT alpha_solid = as.find_alpha_solid();
Alpha_iterator opt = as.find_optimal_alpha(1);
std::cout << "Smallest alpha value to get a solid through data points
is "
          << alpha_solid << std::endl;
std::cout << "Optimal alpha value to get one connected component is "
          << *opt << std::endl;
as.set_alpha(*opt);
assert(as.number_of_solid_components() == 1);
return 0;
}

```

File: examples/Alpha_shapes_3/ex_alpha_shapes_with_fast_location_3.cpp

41.4.3 Example for Weighted Alpha-Shapes

The following examples build a weighted alpha shape requiring a regular triangulation as underlying triangulation. The alpha shape is built in *GENERAL* mode.

```

#include <CGAL/Exact_predicates_inexact_constructions_kernel.h>
#include <CGAL/Regular_triangulation_euclidean_traits_3.h>
#include <CGAL/Regular_triangulation_3.h>
#include <CGAL/Alpha_shape_3.h>
#include <list>

typedef CGAL::Exact_predicates_inexact_constructions_kernel K;

typedef CGAL::Regular_triangulation_euclidean_traits_3<K> Gt;

typedef CGAL::Alpha_shape_vertex_base_3<Gt> Vb;
typedef CGAL::Alpha_shape_cell_base_3<Gt> Fb;
typedef CGAL::Triangulation_data_structure_3<Vb,Fb> Tds;
typedef CGAL::Regular_triangulation_3<Gt,Tds> Triangulation_3;
typedef CGAL::Alpha_shape_3<Triangulation_3> Alpha_shape_3;

typedef Alpha_shape_3::Cell_handle Cell_handle;
typedef Alpha_shape_3::Vertex_handle Vertex_handle;
typedef Alpha_shape_3::Facet Facet;
typedef Alpha_shape_3::Edge Edge;
typedef Gt::Weighted_point Weighted_point;
typedef Gt::Bare_point Bare_point;

int main()
{
    std::list<Weighted_point> lwp;

    //input : a small molecule

```

```

lwp.push_back(Weighted_point(Bare_point( 1, -1, -1), 4));
lwp.push_back(Weighted_point(Bare_point(-1, 1, -1), 4));
lwp.push_back(Weighted_point(Bare_point(-1, -1, 1), 4));
lwp.push_back(Weighted_point(Bare_point( 1, 1, 1), 4));
lwp.push_back(Weighted_point(Bare_point( 2, 2, 2), 1));

//build alpha_shape in GENERAL mode and set alpha=0
Alpha_shape_3 as(lwp.begin(), lwp.end(), 0, Alpha_shape_3::GENERAL);

//explore the 0-shape - It is dual to the boundary of the union.
std::list<Cell_handle> cells;
std::list<Facet> facets;
std::list<Edge> edges;
as.get_alpha_shape_cells(std::back_inserter(cells),
                        Alpha_shape_3::INTERIOR);
as.get_alpha_shape_facets(std::back_inserter(facets),
                        Alpha_shape_3::REGULAR);
as.get_alpha_shape_facets(std::back_inserter(facets),
                        Alpha_shape_3::SINGULAR);
as.get_alpha_shape_edges(std::back_inserter(edges),
                        Alpha_shape_3::SINGULAR);
std::cout << " The 0-shape has : " << std::endl;
std::cout << cells.size() << " interior tetrahedra" << std::endl;
std::cout << facets.size() << " boundary facets" << std::endl;
std::cout << edges.size() << " singular edges" << std::endl;
return 0;
}

```

File: examples/Alpha_shapes_3/ex_weighted_alpha_shapes_3.cpp

41.4.4 Example for periodic Alpha Shapes

The following example shows how to use the periodic Delaunay triangulation (Chapter 39) as underlying triangulation for the alpha shape computation.

In order to define the original domain and to benefit from the built-in heuristic optimizations of the periodic Delaunay triangulation computation it is recommended to first construct the triangulation and then construct the alpha shape from it. The alpha shape constructor that takes a point range can be used as well but in this case the original domain cannot be specified and the default unit cube will be chosen and no optimizations will be used.

It is also recommended to switch the triangulation to 1-sheeted covering if possible. Note that a periodic triangulation in 27-sheeted covering space is degenerate. In this case an exact constructions kernel needs to be used to compute the alpha shapes. Otherwise the results will suffer from round-off problems.

```

#include <CGAL/Exact_predicates_inexact_constructions_kernel.h>
#include <CGAL/Periodic_3_triangulation_traits_3.h>
#include <CGAL/Periodic_3_Delaunay_triangulation_3.h>
#include <CGAL/Alpha_shape_3.h>

#include <CGAL/Random.h>
#include <CGAL/point_generators_3.h>

```

```

// Traits
typedef CGAL::Exact_predicates_inexact_constructions_kernel K;
typedef CGAL::Periodic_3_triangulation_traits_3<K> PK;

// Vertex type
typedef CGAL::Periodic_3_triangulation_ds_vertex_base_3<> DsVb;
typedef CGAL::Triangulation_vertex_base_3<PK,DsVb> Vb;
typedef CGAL::Alpha_shape_vertex_base_3<PK,Vb> AsVb;
// Cell type
typedef CGAL::Periodic_3_triangulation_ds_cell_base_3<> DsCb;
typedef CGAL::Triangulation_cell_base_3<PK,DsCb> Cb;
typedef CGAL::Alpha_shape_cell_base_3<PK,Cb> AsCb;

typedef CGAL::Triangulation_data_structure_3<AsVb,AsCb> Tds;
typedef CGAL::Periodic_3_Delaunay_triangulation_3<PK,Tds> P3DT3;
typedef CGAL::Alpha_shape_3<P3DT3> Alpha_shape_3;

typedef PK::Point_3 Point;

int main()
{
    typedef CGAL::Creator_uniform_3<double, Point> Creator;
    CGAL::Random random(7);
    CGAL::Random_points_in_cube_3<Point, Creator> in_cube(1, random);
    std::vector<Point> pts;

    // Generating 1000 random points
    for (int i=0 ; i < 1000 ; i++) {
        Point p = *in_cube++;
        pts.push_back(p);
    }

    // Define the periodic cube
    P3DT3 pdt(PK::Iso_cuboid_3(-1,-1,-1,1,1,1));
    // Heuristic for inserting large point sets (if pts is reasonably
    large)
    pdt.insert(pts.begin(), pts.end(), true);
    // As pdt won't be modified anymore switch to 1-sheeted cover if
    possible
    if (pdt.is_triangulation_in_1_sheet())
        pdt.convert_to_1_sheeted_covering();
    std::cout << "Periodic Delaunay computed." << std::endl;

    // compute alpha shape
    Alpha_shape_3 as(pdt);
    std::cout << "Alpha shape computed in REGULARIZED mode by default."
        << std::endl;

    // find optimal alpha values
    Alpha_shape_3::NT alpha_solid = as.find_alpha_solid();
    Alpha_shape_3::Alpha_iterator opt = as.find_optimal_alpha(1);

3D Alpha Shapes

Reference Manual

Tran Kai Frank Da and Mariette Yvinec

Alpha shapes definition is based on an underlying triangulation that may be a Delaunay triangulation in case of basic alpha shapes or a regular triangulation (cf. [37.3](#)) in case of weighted alpha shapes.

Let us consider the basic case with a Delaunay triangulation. We first define the alpha complex of the set of points S . The alpha complex is a subcomplex of the Delaunay triangulation. For a given value of α , the alpha complex includes all the simplices in the Delaunay triangulation which have an empty circumsphere with squared radius equal or smaller than α . Here “empty” means that the open sphere do not include any points of S . The alpha shape is then simply the domain covered by the simplices of the alpha complex (see [\[EM94\]](#)).

In general, an alpha complex is a non-connected and non-pure complex. This means in particular that the alpha complex may have singular faces. For $0 \leq k \leq d - 1$, a k -simplex of the alpha complex is said to be singular if it is not a facet of a $(k + 1)$ -simplex of the complex. CGAL provides two versions of the alpha shapes. In the general mode, the alpha shapes correspond strictly to the above definition. The regularized mode provides a regularized version of the alpha shapes corresponding to the domain covered by a regularized version of the alpha complex where singular faces are removed.

The alpha shapes of a set of points S form a discrete family, even though they are defined for all real numbers α . The entire family of alpha shapes can be represented through the underlying triangulation of S . In this representation each k -simplex of the underlying triangulation is associated with an interval that specifies for which values of α the k -simplex belongs to the alpha complex. Relying on this fact, the family of alpha shapes can be computed efficiently and relatively easily. Furthermore, we can select the optimal value of α to get an alpha shape including all data points and having less than a given number of connected components.

The definition is analog in the case of weighted alpha shapes. The input set is now a set of weighted points (which can be regarded as spheres) and the underlying triangulation is the regular triangulation of this set. Two spheres, or two weighted points, with centers C_1, C_2 and radii r_1, r_2 are said to be orthogonal iff $C_1 C_2^2 = r_1^2 + r_2^2$ and suborthogonal iff $C_1 C_2^2 < r_1^2 + r_2^2$. For a given value of α the weighted alpha complex is formed with the simplices of the regular triangulation such that there is a sphere orthogonal to the weighted points associated with the vertices of the simplex and suborthogonal to all the other input weighted points. Once again the alpha shape is then defined as the domain covered by the alpha complex and arise in two versions general or regularized.

AlphaShapeCell_3

Definition

This concept describes the requirements for the base cell of an alpha shape.

Refines

TriangulationCellBase_3.

AlphaShapeCell_3:: NT A number type. Must be the same as the number type used in the traits class of the triangulation underlying the alpha shape.

AlphaShapeCell_3:: Alpha_status_iterator An iterator with value type *CGAL::Alpha_status<NT>*.

Creation

AlphaShapeCell_3 f; default constructor.

AlphaShapeCell_3 f(Vertex_handle v0, Vertex_handle v1, Vertex_handle v2, Vertex_handle v3);

constructor setting the incident vertices.

*AlphaShapeCell_3 f(Vertex_handle v0,
Vertex_handle v1,
Vertex_handle v2,
Vertex_handle v3,
Cell_handle n0,
Cell_handle n1,
Cell_handle n2,
Cell_handle n3)*

constructor setting the incident vertices and the neighboring cells.

Access Functions

NT *f.get_alpha()* Returns the alpha value of the cell.

Alpha_status_iterator

f.get_facet_status(int i)

Returns an iterator on the *CGAL::Alpha_status<NT>* of the facet *i* of the cell.

Modifiers

void *f.set_alpha(NT alpha)*

Sets the critical value of the cell.

void *f.set_facet_status(int i, Alpha_status_iterator as)*

Sets the iterator pointing to the *CGAL::Alpha_status<NT>* of the facet *i* of the cell.

See Also

CGAL::Alpha_status

AlphaShapeTraits_3

Definition

The concept `AlphaShapeTraits_3` describes the requirements for the geometric traits class of the underlying Delaunay triangulation of a basic alpha shape.

Refines

DelaunayTriangulationTraits_3

In addition to the requirements described in the concept *DelaunayTriangulationTraits_3*, the geometric traits class of a Delaunay triangulation plugged in a basic alpha shapes provides the following.

Types

AlphaShapeTraits_3::NT A number type compatible with the type used for the points coordinate.

AlphaShapeTraits_3::Compute_squared_radius_3

An object constructor able to compute:
 the squared radius of the smallest circumsphere of 4 points p_0, p_1, p_2, p_3 ,
 the squared radius of the smallest circumsphere of 3 points p_0, p_1, p_2 ,
 the squared radius of the smallest circumsphere of 2 points p_0, p_1 ,
 and also the squared radius of the smallest circumsphere to a single point p_0 (which is $NT(0)$).

Creation

AlphaShapeTraits_3 traits; Default constructor.

Access Functions

Compute_squared_radius_3 *traits.compute_squared_radius_3_object()*

Has Models

All CGAL kernels.

CGAL::Exact_predicates_inexact_constructions_kernel (recommended)

CGAL::Exact_predicates_exact_constructions_kernel

CGAL::Filtered_kernel

CGAL::Cartesian

CGAL::Simple_cartesian

CGAL::Homogeneous

CGAL::Simple_homogeneous

AlphaShapeVertex_3

Definition

This concept describe the requirements for the base vertex of an alpha shape.

Refines

TriangulationVertexBase_3.

Types

AlphaShapeVertex_3:: Point

Must be the same as the point type provided by the geometric traits class of the triangulation.

AlphaShapeVertex_3:: Alpha_status

Must be *CGAL::Alpha_status<NT>* where *NT* is the number type used in the geometric traits class of the triangulation.

Creation

AlphaShapeVertex_3 v;

default constructor.

AlphaShapeVertex_3 v(Point p);

constructor setting the point associated to.

AlphaShapeVertex_3 v(Point p, Cell_handle c);

constructor setting the point associated to and an incident cell.

Modifiers

*Alpha_status**

v.get_alpha_status()

Returns a pointer the alpha status of the vertex.

CGAL::Alpha_status

CGAL::Alpha_shape_3<Dt>

Definition

The class *Alpha_shape_3<Dt>* represents the family of alpha shapes of points in the 3D space for *all* positive α . It maintains an underlying triangulation of the class *Dt* which represents connectivity and order among its faces. Each *k*-dimensional face of the *Dt* is associated with an interval that specifies for which values of α the face belongs to the alpha shape.

Note that this class is at the same time used for *basic* and for *weighted* Alpha Shapes.

```
#include <CGAL/Alpha_shape_3.h>
```

Inherits From

Dt

This class is the underlying triangulation class.

The modifying functions *insert* and *remove* will overwrite the inherited functions. At the moment, only the static version is implemented.

Types

Alpha_shape_3<Dt>:: Gt the alpha shape traits type.

it has to derive from a triangulation traits class. For example *Dt::Point* is a Point class.

```
typedef Gt::FT
```

FT; the number type of alpha values.

Alpha_shape_3<Dt>:: size_type The size type.

Alpha_shape_3<Dt>:: Alpha_iterator

A bidirectional and non-mutable iterator that allow to traverse the increasing sequence of different alpha values.

Precondition: Its *value_type* is *FT*

```
enum Mode { GENERAL, REGULARIZED};
```

In GENERAL mode, the alpha complex can have singular faces, i. e. faces of dimension *k*, for $k = (0, 1, 2)$ that are not subfaces of a $k + 1$ face of the complex. In REGULARIZED mode, the complex is regularized, that is singular faces are dropped and the alpha complex includes only a subset of the tetrahedral cells of the triangulation and the subfaces of those cells.

enum Classification_type { EXTERIOR, SINGULAR, REGULAR, INTERIOR};

Enum to classify the faces of the underlying triangulation with respect to the alpha shape.

In GENERAL mode, for $k = (0, 1, 2)$, each k -dimensional simplex of the triangulation can be classified as EXTERIOR, SINGULAR, REGULAR or INTERIOR. In GENERAL mode a k simplex is REGULAR if it is on the boundary of the alpha complex and belongs to a $k + 1$ simplex in this complex and it is SINGULAR if it is a boundary simplex that is not included in a $k + 1$ simplex of the complex.

In REGULARIZED mode, for $k = (0, 1, 2)$ each k -dimensional simplex of the triangulation can be classified as EXTERIOR, REGULAR or INTERIOR, i.e. there is no singular faces. A k simplex is REGULAR if it is on the boundary of alpha complex and belongs to a tetrahedral cell of the complex.

Creation

Alpha_shape_3<Dt> A(FT alpha = 0, Mode m = REGULARIZED);

Introduces an empty alpha shape data structure A for and set the current alpha value to $alpha$ and the mode to m .

Alpha_shape_3<Dt> A(Dt& dt, FT alpha = 0, Mode m = REGULARIZED);

Build an alpha shape of mode m from the triangulation dt . Be careful that this operation destroy the triangulation.

template < class InputIterator >

Alpha_shape_3<Dt> A(InputIterator first, InputIterator last, FT alpha = 0, Mode m = REGULARIZED);

Build an alpha shape data structure in mode m for the points in the range $[first, last)$ and set the current alpha value to $alpha$.

Precondition: The *value_type* of *first* and *last* is *Point* (the type point of the underlying triangulation.)

Modifiers

template < class InputIterator >

std::ptrdiff_t A.make_alpha_shape(InputIterator first, InputIterator last)

Initialize the alpha shape data structure for points in the range $[first, last)$. Returns the number of data points inserted in the underlying triangulation.

If the function is applied to an non-empty alpha shape data structure, it is cleared before initialization.

Precondition: The *value_type* of *first* and *last* is *Point*.

void A.clear() Clears the structure.

<i>FT</i>	<i>A.set_alpha(FT alpha)</i>	Sets the α -value to <i>alpha</i> . Returns the previous α -value. <i>Precondition: alpha</i> ≥ 0 .
<i>Mode</i>	<i>A.set_mode(Mode m = REGULARIZED)</i>	Sets <i>A</i> in GENERAL or REGULARIZED. Returns the previous mode. Changing the mode of an alpha shape data structure entails a partial re-computation of the data structure.

Query Functions

<i>Mode</i>	<i>A.get_mode(void)</i>	Returns whether <i>A</i> is general or regularized.
<i>FT</i>	<i>A.get_alpha(void)</i>	Returns the current α -value.
<i>FT</i>	<i>A.get_nth_alpha(int n)</i>	Returns the <i>n</i> -th alpha-value, sorted in an increasing order. <i>Precondition: n</i> \leq number of alphas.
<i>size_type</i>	<i>A.number_of_alphas()</i>	Returns the number of different alpha-values.
<i>Classification_type</i>	<i>A.classify(Point p, FT alpha = get_alpha())</i>	Locates a point <i>p</i> in the underlying triangulation and Classifies the associated k-face with respect to <i>alpha</i> .
<i>Classification_type</i>	<i>A.classify(Cell_handle f, FT alpha = get_alpha())</i>	Classifies the cell <i>f</i> of the underlying triangulation with respect to <i>alpha</i> .
<i>Classification_type</i>	<i>A.classify(Facet f, FT alpha = get_alpha())</i>	Classifies the facet <i>e</i> of the underlying triangulation with respect to <i>alpha</i> .

Classification_type

A.classify(Cell_handle f, int i, FT alpha = get_alpha())

Classifies the facet of the cell *f* opposite to the vertex with index *i* of the underlying triangulation with respect to *alpha*.

Classification_type

A.classify(Edge e, FT alpha = get_alpha())

Classifies the edge *e* with respect to *alpha* .

Classification_type

A.classify(Vertex_handle v, FT alpha = get_alpha())

Classifies the vertex *v* of the underlying triangulation with respect to *alpha*.

template<class OutputIterator>
OutputIterator

A.get_alpha_shape_cells(OutputIterator it, Classification_type type, FT alpha = get_alpha())

Write the cells which are of type *type* for the alpha value *alpha* to the sequence pointed to by the output iterator *it*. Return past the end of the output sequence.

template<class OutputIterator>
OutputIterator

A.get_alpha_shape_facets(OutputIterator it,
Classification_type type,
FT alpha= get_alpha())

Write the facets which are of type *type* for the alpha value *alpha* to the sequence pointed to by the output iterator *it*. Return past the end of the output sequence.

template<class OutputIterator>
OutputIterator

A.get_alpha_shape_edges(OutputIterator it,
Classification_type type,
FT alpha = get_alpha())

Write the edges which are of type *type* for the alpha value *alpha* to the sequence pointed to by the output iterator *it*. Return past the end of the output sequence.

```
template<class OutputIterator>
OutputIterator
```

```
A.get_alpha_shape_vertices( OutputIterator it,
                             Classification_type type,
                             FT alpha) get_alpha())
```

Write the vertices which are of type *type* for the alpha value *alpha* to the sequence pointed to by the output iterator *it*. Return past the end of the output sequence.

```
template<class OutputIterator>
OutputIterator
```

```
A.filtration( OutputIterator it)
```

Output all the faces of the triangulation in increasing order of the alpha value for which they appear in the alpha complex. In case of equal alpha value lower dimensional faces are output first. The value type of the OutputIterator has to be a CGAL::Object

Traversal of the α -Values

Alpha_iterator

```
A.alpha_begin()
```

 Returns an iterator that allows to traverse the sorted sequence of α -values of the family of alpha shapes.

Alpha_iterator

```
A.alpha_end()
```

 Returns the corresponding past-the-end iterator.

Alpha_iterator

```
A.alpha_find( FT alpha)
```

 Returns an iterator pointing to an element with α -value *alpha*, or the corresponding past-the-end iterator if such an element is not found.

Alpha_iterator

```
A.alpha_lower_bound( FT alpha)
```

 Returns an iterator pointing to the first element with α -value not less than *alpha*.

Alpha_iterator

```
A.alpha_upper_bound( FT alpha)
```

 Returns an iterator pointing to the first element with α -value greater than *alpha*.

Operations

size_type *A.number_of_solid_components(FT alpha = get_alpha())*

Returns the number of solid components of *A*, that is, the number of components of its regularized version.

Alpha_iterator

A.find_optimal_alpha(size_type nb_components)

Returns an iterator pointing to smallest α value such that *A* satisfies the following two properties:

all data points are either on the boundary or in the interior of the regularized version of *A*.

The number of solid component of *A* is equal to or smaller than *nb_components*.

I/O

The I/O operators are defined for *iostream*, and for the window stream provided by CGAL. The format for the *iostream* is an internal format.

#include <CGAL/IO/io.h>

ostream& *ostream& os << A* Inserts the alpha shape *A* for the current alpha value into the stream *os*.
Precondition: The insert operator must be defined for *Point*.

#include <CGAL/IO/Geomview_stream.h>

#include <CGAL/IO/alpha_shape_geomview_ostream_3.h>

Geomview_stream&

Geomview_stream& W << A

Inserts the alpha shape *A* for the current alpha value into the Geomview stream *W*.

Precondition: The insert operator must be defined for *Point* and *Triangle*.

Implementation

In GENERAL mode, the alpha intervals of each triangulation face is computed and stored at initialization time. In REGULARIZED mode, the alpha shape intervals of edges are not stored nor computed at initialization. Edges are simply classified on the fly upon request. This allows to have much faster building of alpha shapes in REGULARIZED mode.

A.alpha find uses linear search, while *A.alpha lower bound* and *A.alpha upper bound* use binary search. *A.number of solid components* performs a graph traversal and takes time linear in the number of cells of the underlying triangulation. *A.find of optimal alpha* uses binary search and takes time $O(n \log n)$, where *n* is the number of points.

CGAL::Alpha_shape_cell_base_3<Traits,Fb>

Definition

The class *Alpha_shape_cell_base_3<Traits,Fb>* is the default model for the concept *AlphaShapeCell_3*.

The class has two parameters. The traits class *Traits* provides the number type for alpha values. The second parameter *Fb* is a base class instantiated by default with *CGAL::Triangulation_cell_base_3<Traits>*.

CGAL::Alpha_status<NT>

Definition

The class *Alpha_status*<NT> is a small data structure to store the critical alpha values of faces of an alpha shape. Each face has three critical alpha values, called *alpha_min*, *alpha_mid* and *alpha_max* in increasing order. The face will be exterior for any $\alpha < \text{alpha_min}$, singular for $\text{alpha_min} \leq \alpha < \text{alpha_mid}$, regular for $\text{alpha_mid} \leq \alpha < \text{alpha_max}$ and interior for $\text{alpha_max} \leq \alpha$. The value *alpha_min* is undefined for faces which are not Gabriel faces and therefore do not appear in the alpha complex without any of their including face. The value *alpha_max* is undefined for convex hull faces which can never be interior, The data structure also includes two Boolean to mark if the face is a Gabriel face or a convex hull face.

The class *Alpha_status*<*NT*> is parameterized by a number type *NT*.

```
#include <CGAL/Alpha_shape_cell_base_3.h>
```

Creation

Alpha_status<NT> *a*; default constructor.

Modifiers

<i>void</i>	<i>a.set_is_Gabriel(bool yesorno)</i>	
		sets Gabriel marker;
<i>void</i>	<i>a.set_is_on_chull(bool yesorno)</i>	
		sets convex hull marker;
<i>void</i>	<i>a.set_alpha_min(NT alpha)</i>	
		sets <i>alpha_min</i> .
<i>void</i>	<i>a.set_alpha_mid(NT alpha)</i>	
		sets <i>alpha_mid</i> .
<i>void</i>	<i>a.set_alpha_max(NT alpha)</i>	
		sets <i>alpha_max</i> .

Access Functions

<i>bool</i>	<i>a.is_Gabriel()</i>	Returns true for Gabriel faces;
<i>bool</i>	<i>a.is_on_chull()</i>	Returns true for convex hull faces;
<i>NT</i>	<i>a.alpha_min()</i>	Returns the <i>alpha_min</i> <i>Precondition: is_Gabriel()</i> returns false;
<i>NT</i>	<i>a.alpha_mid()</i>	Returns the <i>alpha_mid</i> ;
<i>NT</i>	<i>a.alpha_max()</i>	Returns <i>alpha_max</i> . <i>Precondition: is_on_chull()</i> returns false.

Definition

The concept `WeightedAlphaShapeTraits_3` describes the requirements for the geometric traits class of the underlying regular triangulation of a weighted alpha shape.

Refines

RegularTriangulationTraits_3

In addition to the requirements described in the concept *RegularTriangulationTraits_3*, the geometric traits class of a Regular triangulation plugged in a basic alpha shapes provides the following.

Types

WeightedAlphaShapeTraits_3::NT

A number type compatible with the type used for the points coordinates.

WeightedAlphaShapeTraits_3::Compute_squared_radius_smallest_orthogonal_sphere_3

An object constructor able to compute the squared radius of the smallest sphere orthogonal to four weighted points p_0 , p_1 , p_2 , p_3 , and the squared radius of the smallest sphere orthogonal to three weighted points p_0 , p_1 , p_2 , and the squared radius of smallest sphere orthogonal to two weighted points p_0 , p_1 , and the squared radius of the smallest sphere orthogonal to a single point p_0 .

This chapter describes the two-dimensional segment Delaunay graph package of CGAL. We start with a few definitions in Section [42.1](#). The software design of the 2D segment Delaunay graph package is described in Section [42.2](#). In Section [42.3](#) we discuss the geometric traits of the 2D segment Delaunay graph package and in Section [42.4](#) the segment Delaunay graph hierarchy, a data structure suitable for fast nearest neighbor queries, is briefly described.

42.1 Definitions

The 2D segment Delaunay graph package of CGAL is designed to compute the Delaunay graph of a set of possibly intersecting segments on the plane. Although we compute the Delaunay graph, we will often refer to its dual, the segment Voronoi diagram, since it is easier to explain and understand. The algorithm that has been implemented is incremental. The corresponding CGAL class is called *Segment_Delaunay_graph_2* <*SegmentDelaunayGraphTraits_2*, *SegmentDelaunayGraphStructure_2*> and will be discussed in more detail in the sequel. The interested reader may want to refer to the paper by Karavelas [[Kar04](#)] for the general idea as well as the details of the algorithm implemented.

Definitions. Before describing the details of the implementation we make a brief introduction to the theory of segment Delaunay graphs and segment Voronoi diagrams. The segment Voronoi diagram is defined over a set

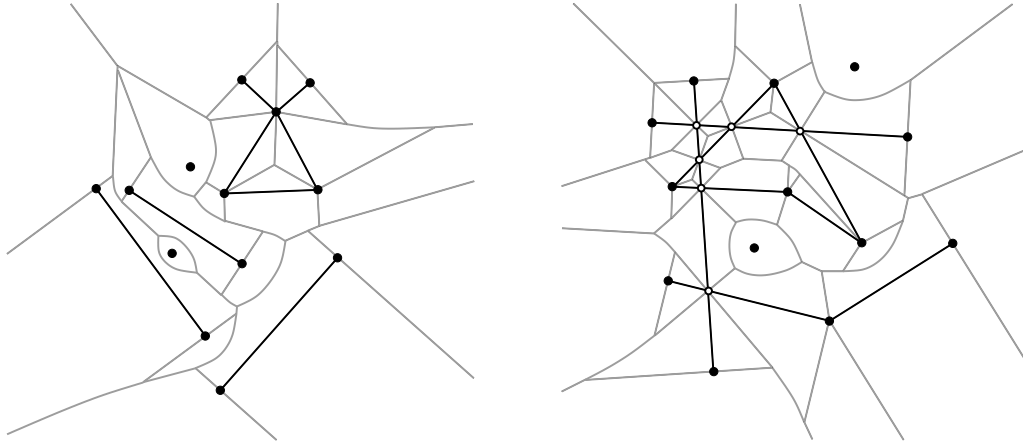

Figure 42.1: The segment Voronoi diagram for a set of weakly (left) and strongly (right) intersecting sites.

of non-intersecting sites, which can either be points or linear segments, which we assume that are given through their endpoints. The segment Voronoi diagram a subdivision of the plane into connected regions, called *cells*, associated with the sites. The dual graph of the segment Voronoi diagram is called the segment Delaunay graph. The cell of a site t_i is the locus of points on the plane that are closer to t_i than any other site t_j , $j \neq i$. The distance $\delta(x, t_i)$ of a point x in the plane to a site t_i is defined as the minimum of the Euclidean distances of x from the points in t_i . Hence, if t_i is a point p_i , then

$$\delta(x, t_i) = \|x - t_i\|,$$

whereas if t_i is a segment, then

$$\delta(x, t_i) = \min_{y \in t_i} \|x - y\|,$$

where $\|\cdot\|$ denotes the Euclidean norm. It can easily be seen that it is a generalization of the Voronoi diagram for points.

In many applications the restriction that sites are non-intersecting is too strict. Often we want to allow segments that touch at their endpoints, or even segments that overlap or intersect properly at their interior (for example, see Fig. 42.1). Allowing such configurations poses certain problems. More specifically, when we allow segments to touch at their endpoints we may end up with pairs of segments whose bisector is two-dimensional. If we allow pairs of segments that intersect properly at their interior, the interiors of their Voronoi cells are no longer simply connected. In both cases above the resulting Voronoi diagrams are no longer instances of abstract Voronoi diagrams (cf. [Kle89]), which has a direct consequence on the efficient computation of the corresponding Voronoi diagram. The remedy to these problems is to consider linear segments not as one object, but rather as three, namely the two endpoints and the interior. This choice guarantees that all bisectors in the Voronoi diagram are one-dimensional and that all Voronoi cells are simply connected. Moreover, we further distinguish between two cases, according to the type of intersecting pair that our input data set contains. A pair of sites is called *weakly intersecting* if they have a single common point and this common point does not lie in the interior of any of the two sites. A pair of sites is called *strongly intersecting* if they intersect and they either have more than one common point or their common point lies in the interior of at least one of the two sites. As it will be seen later the two cases have different representation (and thus storage) requirements, as well as they require a somehow different treatment on how the predicates are evaluated. Having made the distinction between weakly and strongly intersecting sites, and having said that segment sites are treated as three objects, we are now ready to precisely define the Delaunay graph we compute. Given a set \mathcal{S} of input sites, let $\mathcal{S}_{\mathcal{A}}$ be the set of points and (open) segments in the arrangement $\mathcal{A}(\mathcal{S})$ of \mathcal{S} . The 2D segment Delaunay graph package of CGAL computes the (triangulated) Delaunay graph that is dual to the Euclidean Voronoi diagram of the sites in the set $\mathcal{S}_{\mathcal{A}}$.

The segment Delaunay graph is uniquely defined once we have the segment Voronoi diagram. If the all sites are

in *general position*, then Delaunay graph is a graph with triangular faces away from the convex hull of the set of sites. To unify our approach and handling of the Delaunay graph we add to the set of (finite) sites a fictitious site at infinity, which we call the *site at infinity*. We can then connect all vertices of the outer face of the Delaunay graph to the site at infinity which gives us a graph with the property that all of its faces are now triangular. However, the Delaunay graph is not a triangulation for two main reasons: we cannot always embed it on the plane with straight line segments that yield a triangulation and, moreover, we may have two faces of the graph that have two edges in common, which is not allowed in a triangulation.

We would like to finish our brief introduction to the theory of segment Delaunay graphs and segment Voronoi diagrams by discussing the concept of general position. We say that a set of sites is in general position if no two triplets of sites have the same tritangent Voronoi circle. This statement is rather technical and it is best understood in the context of points. The equivalent statement for points is that we have no two triplets of points that define the same circumcircle, or equivalently that no four points are co-circular. The statement about general position made above is a direct generalization of the (much simpler to understand) statement about points. On the contrary, when we have sites in degenerate position, the Delaunay graph has faces with more than three edges on their boundary. We can get a triangulated version of the Delaunay graph by simply *triangulating* the corresponding faces in an arbitrary way. In fact the algorithm that has been implemented in CGAL has the property that it always returns a valid *triangulated* version of the segment Delaunay graph. By valid we mean that it contains the actual (non-triangulated) Delaunay graph, and whenever there are faces with more than three edges then they are triangulated. The way that they are triangulated depends on the order of insertion of the sites in the diagram.

One final remark has to be made with respect to the difference between the set of *input sites* and the set of *output sites*. The set of input sites consists of the closed sites that the user inserts in the diagram. Since segment sites are treated as three objects, internally our algorithm sees only points and open segments. As a result, from the point of view of the algorithm, the input sites have no real meaning. What has real meaning is the set of sites that correspond to cells of the Voronoi diagram and this is the set of output sites.

Degenerate Dimensions. The dimension of the segment Delaunay graph is in general 2. The exceptions to this rule are as follows:

- The dimension is -1 if the segment Delaunay graph contains no sites.
- The dimension is 0 if the segment Delaunay graph contains exactly one (output) site.
- The dimension is 1 if the segment Delaunay graph contains exactly two (output) sites.

42.2 Software Design

The 2D segment Delaunay graph class `SegmentDelaunay_graph_2<SegmentDelaunayGraphTraits_2, SegmentDelaunayGraphDataStructure_2>` follows the design of the triangulation package of CGAL. It is parametrized by two arguments:

- the **geometric traits** class. It provides the basic geometric objects involved in the algorithm, such as sites, points etc. It also provides the geometric predicates for the computation of the segment Delaunay graph, as well as some basic constructions that can be used, for example, to visualize the diagram. The geometric traits for the segment Delaunay graph will be discussed in more detail in the next section.
- the **segment Delaunay graph data structure**. This is essentially the same as the Apollonius graph data structure (discussed in Chapter 43.2), augmented with some additional operations that are specific to segment Voronoi diagrams. The corresponding concept is that of `SegmentDelaunayGraphDataStructure_2`,

which in fact is a refinement of the *ApolloniusGraphDataStructure_2* concept. The class *Triangulation_data_structure_2*<*Vb,Fb*> is a model of the concept *SegmentDelaunayGraphDataStructure_2*. A default value for the corresponding template parameter is provided, so the user does not need to specify it.

Strongly Intersecting Sites and their Representation. As we have mentioned above, the segment Delaunay graph package of CGAL is designed to support the computation of the segment Voronoi diagram even when the input segment sites are intersecting. This choice poses certain issues for the design of the software package. The major concern is the representation of the subsegments that appear in the arrangement of these sites, because the sites in the arrangement are the ones over which the diagram is actually defined. A direct consequence of the choice of representation is the algebraic degree of the predicates involved in the computation of the segment Delaunay graph, as well as the storage requirements for the subsegments and points on intersection in the arrangement.

The case of weakly intersecting sites does not require any special treatment. We can simply represent points by their coordinates and segments by their endpoints. In the case of strongly intersecting sites, the obvious choice to use the afore-mentioned representation has severe disadvantages. Consider two strongly intersecting segments t_i and t_j , whose endpoints have homogeneous coordinates of size b . Their intersection point will have homogeneous coordinates of bit size $6b + O(1)$. This effect can be cascaded, which implies that after inserting k (input) segments we can arrive at having points of intersection whose bit sizes are exponential with respect to k , i.e., their homogeneous coordinates will have bit size $\Omega(2^k b)$. Not only the points of intersection, but also the adjacent subsegments will be represented by quantities of arbitrarily high bit size, and as a result we would not be able to give a bound on the bit sizes of the coordinates of the points of intersection. As a result, we would not be able to give a bound on the memory needed to store these coordinates. An equally important consequence is that we would also not be able to give a bound on the algebraic degree of the algebraic expressions involved in the evaluation of the predicates.

Such a behavior is obviously undesirable. For robustness, efficiency, and scalability purposes, it is critical that the bit size of the algebraic expressions in the predicates does not depend on the input size. For this reason, as well as for others to be discussed below, we decided to represent sites in an implicit manner, which somehow encodes the history of their construction. In particular, we exploit the fact that points of intersection always lie on two input segments, and that segments that are not part of the input are always supported by input segments.

For example, let us consider the configuration in Fig. 42.2. We assume that the segments $t_i = p_i q_i$, $i = 1, 2, 3$, are inserted in that order. Upon the insertion of t_2 , our algorithm will split the segment t_1 into the subsegments $p_1 s_1$ and $s_1 q_1$, then add s_1 , and finally insert the subsegments $p_2 s_1$ and $s_1 q_2$. How do we represent the five new sites? s_1 will be represented by its two defining segments t_1 and t_2 . The segment $p_1 s_1$ will be represented by two segments, a point, and a boolean. The first segment is t_1 , which is always the segment with the same support as the newly created segment. The second segment is t_2 and the point is p_1 . The boolean indicates whether the first endpoint of $p_1 s_1$ is an input point; in this case the boolean is equal to *true*. The segment $s_1 q_1$ will also be represented by two segments, a point, and a boolean, namely, t_1 (the supporting segment of $s_1 q_1$), t_2 and *false* (it is the second endpoint of $s_1 q_1$ that is an input point). Subsegments $p_2 s_1$ and $s_1 q_2$ are represented analogously. Consider now what happens when we insert t_3 . The point s_2 will again be represented by two segments, but not $s_1 q_1$ and t_3 . In fact, it will be represented by t_1 (the supporting segment of $s_1 q_1$) and t_3 . $s_2 q_1$ will be represented by two segments, a point, and a boolean (t_1 , t_3 , q_1 and *false*), and similarly for $p_3 s_2$ and $s_2 q_3$. On the other hand, both endpoints of $s_1 s_2$ are non-input points. In such a case we represent the segment by three input segments. More precisely, $s_1 s_2$ is represented by the segments t_1 (the supporting segment of $s_1 q_1$), t_2 (it defines s_1 along with t_1) and t_3 (it defines s_2 along with t_1).

The five different presentations, two for points (coordinates; two input segments) and three for segments (two input points; two input segments, an input point and a boolean; three input segments), form a closed set of representations and thus represent any point of intersection or subsegment regardless of the number of input segments. Moreover, every point (input or intersection) has homogeneous coordinates of bit size at most $3b + O(1)$. The supporting lines of the segments (they are needed in some of the predicates) have coefficients which are always of bit size $2b + O(1)$. As a result, the bit size of the expressions involved in our predicates will always

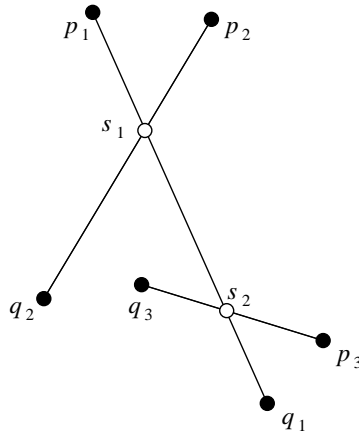

Figure 42.2: Site representation. The point s_1 is represented by the four points p_1 , q_1 , p_2 and q_2 . The segment p_1s_1 is represented by the points p_1 , q_1 , p_2 , q_2 and a boolean which is set to *true* to indicate that the first endpoint is not a point of intersection. The segment s_1s_2 is represented by the six points: p_1 , q_1 , p_2 , q_2 , p_3 and q_3 . The remaining (non-input) points and segments in the figure are represented similarly.

be $O(b)$, independently of the size of the input. The *SegmentDelaunayGraphSite_2* concept encapsulates the ideas presented above. A site is represented in this concept by up to four points and a boolean, or up to six points, depending on its type. The class *Segment_Delaunay_graph_site_2<K>* implements this concept.

Even this representation, however, has some degree of redundancy. The endpoint of a segment appears in both the representation of the (open) segment site as well as the representation of the point site itself. The situation becomes even worse in the presence of strongly intersecting sites: a point may appear in the representation of multiple subsegments and/or points of intersection. To avoid this redundancy, input points are stored in a container, and the various types of sites (input points and segments, points of intersection, subsegments with one or two points of intersection as endpoints) only store handles to the points in the container. This is achieved by the *Segment_Delaunay_graph_storage_site_2<Gt>* class which is a model of the corresponding concept: *SegmentDelaunayGraphStorageSite_2*. This concept enforces a site to be represented by up to 6 handles (which are very lightweight objects) instead of 6 points, which are, compared to handles of course, very heavy objects.

Optimizing Memory Allocation. There are applications where we know beforehand that the input consists of only weakly intersecting sites. In these cases the site representation described above poses a significant overhead in the memory requirements of our implementation: instead of representing sites with up to two points (or ultimately with up to two handles), we require sites to store six points (respectively, six handles). To avoid this overhead we have introduced two series of traits classes:

- One that supports the full-fledged sites, and is suitable when the input consists of strongly intersecting sites. This series consists of the *Segment_Delaunay_graph_traits_2<K,MTag>* and *Segment_Delaunay_graph_filtered_traits_2<CK,CM,EK,EM,FK,FM>* classes.
- One that is customized for input that contain only weakly intersecting sites. This series consists of the *Segment_Delaunay_graph_traits_without_intersections_2<K,MTag>* and *Segment_Delaunay_graph_filtered_traits_without_intersections_2<CK,CM,EK,EM,FK,FM>* classes.

The advantages of having different traits classes are as follows:

- When the user chooses to use one of the traits classes in the second series we only store two handles per site. This implies a reduction by a factor of three in the memory allocated per site with respect to the first series of traits classes.
- In the case of the first series of traits classes, we can better exploit the knowledge that have strongly intersecting sites, in order to further apply geometric filters (see below) during the evaluation of the predicates. On the contrary, if the second series of traits classes is used, we can avoid geometric filtering tests that have meaning only in the case of strongly intersecting sites.

42.3 The Geometric Traits

The predicates required for the computation of the segment Voronoi diagram are rather complicated. It is not the purpose of this document to discuss them in detail. The interested reader may refer to Burnikel's thesis [Bur96], where it is shown that in the case of weakly intersecting sites represented in homogeneous coordinates of bit size b , the maximum bit size of the algebraic expressions involved in the predicates is $40b + O(1)$. Given our site representation given above we can guarantee that even in the case of strongly intersecting sites, the algebraic degree of the predicates remains $O(b)$, independently of the size of the input. What we want to focus in the remainder of this section are the different kinds of filtering techniques that we have employed in our implementation.

Geometric Filtering. Our representation of sites is coupled very naturally, with what we call *geometric filtering*. The technique amounts to performing simple geometric tests exploiting the representation of our data, as well as the geometric structure inherent in our problem, in order to evaluate predicates in seemingly degenerate configurations. Geometric filtering can be seen as a preprocessing step before performing arithmetic filtering. Roughly speaking, by arithmetic filtering we mean that we first try to evaluate the predicates using a fixed-precision floating-point number type (such as `double`), and at the same time keep error bounds on the numerical errors of the computations we perform. If the numerical errors are too big and do not permit us to evaluate the predicate, we switch to an exact number type, and repeat the evaluation of the predicate. Geometric filtering can help by eliminating situations in which the arithmetic filter will fail, thus decreasing the number of times we need to evaluate a predicate using exact arithmetic.

To illustrate the application and effectiveness of this approach, let us consider a very simple example usage. Suppose we want to determine if two non-input points are identical (we assume here that the input sites are represented by *doubles*). In order to do that we need to compute their coordinates and compare them. If the two points are identical, the answer to our question using *double* arithmetic may be wrong (due to numerical errors), in which case we will have to reside to the more expensive exact computation. Instead, before testing the coordinates for equality, we can use the representation of the points to potentially answer the question. More specifically, and this is the geometric filtering part of the computation, we can first test if the defining segments of the two points are the same. If they are not, then we proceed to comparing their coordinates as usual. Testing the defining segments for equality does not involve any arithmetic operations on the input, but rather only comparisons on *doubles*. By performing this very simple test we avoid a numerically difficult computation, which could be performed thousands of times during the computation of a Delaunay graph.

Geometric filtering has been implemented in all our models of the *SegmentDelaunayGraphTraits_2* concept. These models are the classes: *Segment_Delaunay_graph_traits_2*< $K, MTag$ >, *Segment_Delaunay_graph_traits_without_intersections_2*< $K, MTag$ >, *Segment_Delaunay_graph_filtered_traits_2*< CK, CM, EK, EM, FK, FM > and *Segment_Delaunay_graph_filtered_traits_without_intersections_2*< CK, CM, EK, EM, FK, FM >.

Arithmetic Filtering. As mentioned above, performing computations with exact arithmetic can be very costly. For this reason we have devoted considerable effort in implementing different kinds of arithmetic filtering

mechanisms. Presently, there two ways of performing arithmetic filtering for the predicates involved in the computation of segment Delaunay graphs:

1. The user can define his/her kernel using as number type, a number type of the form *CGAL::Filtered_exact<CT,ET>*. Then this kernel can be entered as the first template parameter in the *Segment_Delaunay_graph_2<K,MTag>* or *Segment_Delaunay_graph_without_intersections_2<K,MTag>* class.
2. The user can define up to three different kernels *CK*, *FK* and *EK* (default values are provided for most parameters). The first kernel *CK* is used only for constructions. The second kernel *FK* is the filtering kernel: the traits class will attempt to compute the predicates using this kernel. If the filtering kernel fails to successfully compute a predicate, the exact kernel *EK* will be used. These three kernels are then used in the *Segment_Delaunay_graph_filtered_traits_2<CK,CM,EK,EM,FK,FM>* and *Segment_Delaunay_graph_filtered_traits_without_intersections_2<CK,CM,EK,EM,FK,FM>* classes, which have been implemented using the *Filtered_predicate<EP,FP>* mechanism.

Our experience so far has shown that for all reasonable and valid values of the template parameters, the second method for arithmetic filtering is more efficient among the two.

Let's consider once more the classes *Segment_Delaunay_graph_2<K,MTag>* and *Segment_Delaunay_graph_without_intersections_2<K,MTag>*. The template parameter *MTag* provides another degree of freedom to the user, who can indicate the type of arithmetic operations to be used in the evaluation of the predicates. More specifically, in both classes, *MTag* can be *CGAL::Field_with_sqrt_tag*, in which case the predicates will be evaluated using all four basic arithmetic operations plus square roots; this requires, of course, that the number type used in the kernel *K* supports these operations exactly. The second choices are *CGAL::Field_tag* for the *Segment_Delaunay_graph_2<K,MTag>* class, and *CGAL::Euclidean_ring_tag* for the *Segment_Delaunay_graph_without_intersections_2<K,MTag>* class. In the first case we indicate that we want the predicates to be computed using only the four basic arithmetic operations, whereas in the second case we evaluate the predicates using only ring operations. Again, for the predicates to be evaluated correctly, the number type used in the kernel *K* must support the corresponding operations exactly.

The semantics for the template parameters *CM*, *FM* and *EM* in the *Segment_Delaunay_graph_filtered_traits_2<CK,CM,EK,EM,FK,FM>* and *Segment_Delaunay_graph_filtered_traits_without_intersections_2<CK,CM,EK,EM,FK,FM>* classes are analogous. With each of these template parameters we can control the type of arithmetic operations that are going to be used in calculations involving each of the corresponding kernels *CK*, *FK* and *EK*. When the *Segment_Delaunay_graph_filtered_traits_2<CK,CM,EK,EM,FK,FM>* is used the possible values for *CM*, *FM* and *EM* are *CGAL::Field_with_sqrt_tag* and *CGAL::Field_tag*, whereas if the *Segment_Delaunay_graph_filtered_traits_without_intersections_2<CK,CM,EK,EM,FK,FM>* class is used, the possible values are *CGAL::Field_with_sqrt_tag* and *CGAL::Euclidean_ring_tag*. The semantics are the same as in the case of the *Segment_Delaunay_graph_2<K,MTag>* and *Segment_Delaunay_graph_without_intersections_2<K,MTag>* classes.

42.4 The Segment Delaunay Graph Hierarchy

The *Segment_Delaunay_graph_hierarchy_2<SegmentDelaunayGraphTraits_2, SSTag, SegmentDelaunayGraphDataStructure_2>* class is the analogue of the *Triangulation_hierarchy_2* or the *Apollonius_graph_hierarchy_2* classes, applied to the segment Delaunay graph. It consists of a hierarchy of segment Delaunay graphs constructed in a manner analogous to the Delaunay hierarchy by Devillers [Dev02]. Unlike the triangulation hierarchy or the Apollonius graph hierarchy, the situation here is more complicated because of two factors: firstly, segments are treated as three objects instead of one (the two endpoints and the interior of the segments), and secondly, the presence of strongly intersecting sites complicates significantly the way the hierarchy is constructed. The interested reader may refer to the paper by Karavelas [Kar04] for the

details of the construction of the hierarchy. Another alternative is to have a hybrid hierarchy that consists of the segment Delaunay graph at the bottom-most level and point Voronoi diagrams at all other levels. This choice seems to work very well in practice, primarily because it avoids the overhead of maintaining a Delaunay graph for segments at the upper levels of the hierarchy. However, it seems much less likely to be possible to give any theoretical guarantees for its performance, in contrast to the hierarchy with segment Delaunay graphs at all levels (cf. [Kar04]). The user can choose between the two types of hierarchies by means of the template parameter *SSTag*. If *SSTag* is set to *false* (which is also the default value), the upper levels of the hierarchy consist of point Delaunay graphs. If *SSTag* is set to *true*, we have segment Delaunay graphs at all levels of the hierarchy.

The class `Segment_Delaunay_graph_hierarchy_2<SegmentDelaunayGraphTraits_2, SSTag, SegmentDelaunayGraphDataStructure_2>` has exactly the same interface and functionality as the `Segment_Delaunay_graph_2<SegmentDelaunayGraphTraits_2, SegmentDelaunayGraphDataStructure_2>` class. Using the segment Delaunay graph hierarchy involves an additional cost in space and time for maintaining the hierarchy. Our experiments have shown that it usually pays off to use the hierarchy for inputs consisting of more than about 1,000 sites.

42.5 Examples

42.5.1 First Example

The following example shows how to use the segment Delaunay graph traits in conjunction with the *Filtered_exact<CT,ET>* mechanism. In addition it shows how to use a few of the iterators provided by the `Segment_Delaunay_graph_2` class in order to count a few site-related quantities.

```
#include <CGAL/basic.h>

// standard includes
#include <iostream>
#include <fstream>
#include <cassert>

// define the exact number type
# include <CGAL/Quotient.h>
# include <CGAL/MP_Float.h>
typedef CGAL::Quotient<CGAL::MP_Float> ENT;

// define the kernels
#include <CGAL/Simple_cartesian.h>

typedef CGAL::Simple_cartesian<double> CK;
typedef CGAL::Simple_cartesian<ENT> EK;

// typedefs for the traits and the algorithm
#include <CGAL/Segment_Delaunay_graph_filtered_traits_2.h>
#include <CGAL/Segment_Delaunay_graph_2.h>

typedef CGAL::Segment_Delaunay_graph_filtered_traits_2<CK,
/* The construction kernel allows for / and sqrt */
CGAL::Field_with_sqrt_tag,
EK,
```

```

/* The exact kernel supports field ops exactly */      CGAL::Field_tag>
    Gt;

typedef CGAL::Segment_Delaunay_graph_2<Gt>            SDG2;

using namespace std;

int main() {
    ifstream ifs("data/sitesx.cin");
    assert( ifs );

    SDG2          sdg;
    SDG2::Site_2  site;

    while ( ifs >> site ) { sdg.insert( site ); }

    ifs.close();

    assert( sdg.is_valid(true, 1) );
    cout << endl << endl;

    // print the number of input and output sites
    cout << "# of input sites : " << sdg.number_of_input_sites() << endl;
    cout << "# of output sites: " << sdg.number_of_output_sites() << endl;

    unsigned int n_ipt(0), n_iseg(0), n_opt(0), n_oseg(0), n_ptx(0);

    // count the number of input points and input segments
    SDG2::Input_sites_iterator iit;
    for (iit = sdg.input_sites_begin(); iit != sdg.input_sites_end();
        ++iit)
    {
        if ( iit->is_point() ) { n_ipt++; } else { n_iseg++; }
    }

    // count the number of output points and output segments, as well
    // as the number of points that are points of intersection of pairs
    // of strongly intersecting sites
    SDG2::Output_sites_iterator oit;
    for (oit = sdg.output_sites_begin(); oit != sdg.output_sites_end();
        ++oit)
    {
        if ( oit->is_segment() ) { n_oseg++; } else {
            n_opt++;
            if ( !oit->is_input() ) { n_ptx++; }
        }
    }

    cout << endl << "# of input segments:  " << n_iseg << endl;
    cout << "# of input points:      " << n_ipt << endl << endl;
    cout << "# of output segments: " << n_oseg << endl;
    cout << "# of output points:   " << n_opt << endl << endl;
    cout << "# of intersection points: " << n_ptx << endl;

```

```
    return 0;
}
```

File: examples/Segment_Delaunay_graph_2/sdg-count-sites.cpp

42.5.2 Second Example

The following example shows how to use the segment Delaunay graph hierarchy along with the filtered traits class that supports intersecting sites.

```
#include <CGAL/basic.h>

// standard includes
#include <iostream>
#include <fstream>
#include <cassert>

// example that uses the filtered traits and
// the segment Delaunay graph hierarchy

// choose the kernel
#include <CGAL/Simple_cartesian.h>

struct Rep : public CGAL::Simple_cartesian<double> {};

// typedefs for the traits and the algorithm
#include <CGAL/Segment_Delaunay_graph_hierarchy_2.h>
#include <CGAL/Segment_Delaunay_graph_filtered_traits_2.h>

struct Gt
  : public CGAL::Segment_Delaunay_graph_filtered_traits_2<Rep> {};

typedef CGAL::Segment_Delaunay_graph_hierarchy_2<Gt>   SDG2;

int main()
{
    std::ifstream ifs("data/sites.cin");
    assert( ifs );

    SDG2          sdg;
    SDG2::Site_2  site;

    // read the sites and insert them in the segment Delaunay graph
    while ( ifs >> site ) {
        sdg.insert(site);
    }

    // validate the segment Delaunay graph
    assert( sdg.is_valid(true, 1) );

    return 0;
}
```

```
}
```

File: examples/Segment_Delaunay_graph_2/sdg-filtered-traits.cpp

42.5.3 Third Example

The following example demonstrates how to recover the defining sites for the edges of the Voronoi diagram (which are the duals of the edges of the segment Delaunay graph computed).

```
#include <CGAL/basic.h>

// standard includes
#include <iostream>
#include <fstream>
#include <cassert>
#include <string>

// define the kernel
#include <CGAL/Simple_cartesian.h>
#include <CGAL/Filtered_kernel.h>

typedef CGAL::Simple_cartesian<double> CK;
typedef CGAL::Filtered_kernel<CK> Kernel;

// typedefs for the traits and the algorithm
#include <CGAL/Segment_Delaunay_graph_traits_2.h>
#include <CGAL/Segment_Delaunay_graph_2.h>

typedef CGAL::Segment_Delaunay_graph_traits_2<Kernel> Gt;
typedef CGAL::Segment_Delaunay_graph_2<Gt> SDG2;

using namespace std;

int main()
{
    ifstream ifs("data/sites2.cin");
    assert( ifs );

    SDG2 sdg;
    SDG2::Site_2 site;

    // read the sites from the stream and insert them in the diagram
    while ( ifs >> site ) { sdg.insert( site ); }

    ifs.close();

    // validate the diagram
    assert( sdg.is_valid(true, 1) );
    cout << endl << endl;

    /*
    // now walk through the non-infinite edges of the segment Delaunay
```

```

// graphs (which are dual to the edges in the Voronoi diagram) and
// print the sites defining each Voronoi edge.
//
// Each oriented Voronoi edge (horizontal segment in the figure
// below) is defined by four sites A, B, C and D.
//
//
//      \      B      /
//      /      \      \
//      /      /      \
//      /      /      \
//      /      /      \
//      /      /      \
//      /      /      \
//      /      /      \
//
// The sites A and B define the (oriented) bisector on which the
// edge lies whereas the sites C and D, along with A and B define
// the two endpoints of the edge. These endpoints are the Voronoi
// vertices of the triples A, B, C and B, A, D.
// If one of these vertices is the vertex at infinity the string
// "infinite vertex" is printed; the corresponding Voronoi edge is
// actually a straight-line or parabolic ray.
// The sites below are printed in the order A, B, C, D.
*/

string inf_vertex("infinite vertex");
char vid[] = {'A', 'B', 'C', 'D'};

SDG2::Finite_edges_iterator eit = sdg.finite_edges_begin();
for (int k = 1; eit != sdg.finite_edges_end(); ++eit, ++k) {
    SDG2::Edge e = *eit;
    // get the vertices defining the Voronoi edge
    SDG2::Vertex_handle v[] = { e.first->vertex( sdg.ccw(e.second) ),
                                e.first->vertex( sdg.cw(e.second) ),
                                e.first->vertex( e.second ),
                                sdg.tds().mirror_vertex(e.first,
e.second) };

    cout << "--- Edge " << k << " ---" << endl;
    for (int i = 0; i < 4; i++) {
        // check if the vertex is the vertex at infinity; if yes, print
        // the corresponding string, otherwise print the site
        if ( sdg.is_infinite(v[i]) ) {
            cout << vid[i] << ": " << inf_vertex << endl;
        } else {
            cout << vid[i] << ": " << v[i]->site() << endl;
        }
    }
    cout << endl;
}

return 0;
}

```

2D Segment Delaunay Graphs

Reference Manual

Menelaos Karavelas

CGAL provides the class `CGAL::Segment_Delaunay_graph_2<Gt,DS>` for computing the 2D Delaunay graph of segments and points. The two template parameters must be models of the `SegmentDelaunayGraphTraits_2` and `SegmentDelaunayGraphDataStructure_2` concepts. The first concept is related to the geometric objects and predicates associated with segment Delaunay graphs, whereas the second concept refers to the data structure used to represent the segment Delaunay graph, which is dual to the 2D Voronoi diagram of segments and points. The classes `Segment_Delaunay_graph_traits_2<K,MTag>`, `Segment_Delaunay_graph_traits_without_intersections_2<K,MTag>`, `Segment_Delaunay_graph_filtered_traits_2<K,MTag>`, `Segment_Delaunay_graph_filtered_traits_without_intersections_2<K,MTag>` are models of the `SegmentDelaunayGraphTraits_2` concept, whereas the class `Triangulation_data_structure_2<Vb,Fb>` is a model of the `SegmentDelaunayGraphDataStructure_2` concept.

CGAL::Segment_Delaunay_graph_2<Gt,DS>

Definition

The class *Segment_Delaunay_graph_2<Gt,DS>* represents the segment Delaunay graph (which is the dual graph of the 2D segment Voronoi diagram). Currently it supports only insertions of sites. It is templated by two template arguments *Gt*, which must be a model of *SegmentDelaunayGraphTraits_2* and *DS*, which must be a model of *SegmentDelaunayGraphDataStructure_2*. The second template argument defaults to *CGAL::Triangulation_data_structure_2< CGAL::Segment_Delaunay_graph_vertex_base_2<Gt>, CGAL::Triangulation_face_base_2<Gt> >*.

```
#include <CGAL/Segment_Delaunay_graph_2.h>
```

Is Model for the Concepts

DelaunayGraph_2

Types

<code>typedef Gt</code>	<code>Geom_traits;</code>	A type for the geometric traits.
<code>typedef DS</code>	<code>Data_structure;</code>	A type for the underlying data structure.
<code>typedef Data_structure</code>	<code>Triangulation_data_structure;</code>	
		This type has been added so that the <i>Segment_Delaunay_graph_2<Gt,DS></i> class is a model of the <i>DelaunayGraph_2</i> concept.
<code>typedef typename DS::size_type</code>	<code>size_type;</code>	Size type (an unsigned integral type)
<code>typedef typename Gt::Point_2</code>	<code>Point_2;</code>	A type for the point defined in the geometric traits.
<code>typedef typename Gt::Site_2</code>	<code>Site_2;</code>	A type for the segment Delaunay graph site, defined in the geometric traits.
<code>Segment_Delaunay_graph_2<Gt,DS>:: Point_container</code>		A type for the container of points.
<code>typedef typename Point_container::iterator</code>	<code>Point_handle;</code>	A handle for points in the point container.

The vertices and faces of the segment Delaunay graph are accessed through *handles*, *iterators* and *circulators*. The iterators and circulators are all bidirectional and non-mutable. The circulators and iterators are assignable to the corresponding handle types, and they are also convertible to the corresponding handles. The edges of the segment Delaunay graph can also be visited through iterators and circulators, the edge circulators and iterators are also bidirectional and non-mutable. In the following, we call *infinite* any face or edge incident to the infinite vertex and the infinite vertex itself. Any other feature (face, edge or vertex) of the segment Delaunay graph is said to be *finite*. Some iterators (the *All* iterators) allow to visit finite or infinite features while the others (the *Finite* iterators) visit only finite features. Circulators visit both infinite and finite features.

<code>typedef typename DS::Edge</code>	<code>Edge;</code>	The edge type. The <i>Edge(f,i)</i> is the edge common to faces <i>f</i> and <i>f.neighbor(i)</i> . It is also the edge joining the vertices <i>vertex(cw(i))</i> and <i>vertex(ccw(i))</i> of <i>f</i> . <i>Precondition:</i> <i>i</i> must be 0, 1 or 2.
--	--------------------	---

<code>typedef typename DS::Vertex</code>	<code>Vertex;</code>	A type for a vertex.
<code>typedef typename DS::Face</code>	<code>Face;</code>	A type for a face.
<code>typedef typename DS::Vertex_handle</code>	<code>Vertex_handle;</code>	A type for a handle to a vertex.
<code>typedef typename DS::Face_handle</code>	<code>Face_handle;</code>	A type for a handle to a face.
<code>typedef typename DS::Vertex_circulator</code>	<code>Vertex_circulator;</code>	A type for a circulator over vertices incident to a given vertex.
<code>typedef typename DS::Face_circulator</code>	<code>Face_circulator;</code>	A type for a circulator over faces incident to a given vertex.
<code>typedef typename DS::Edge_circulator</code>	<code>Edge_circulator;</code>	A type for a circulator over edges incident to a given vertex.
<code>typedef typename DS::Vertex_iterator</code>	<code>All_vertices_iterator;</code>	A type for an iterator over all vertices.
<code>typedef typename DS::Face_iterator</code>	<code>All_faces_iterator;</code>	A type for an iterator over all faces.
<code>typedef typename DS::Edge_iterator</code>	<code>All_edges_iterator;</code>	A type for an iterator over all edges.
<code>Segment_Delaunay_graph_2<Gt,DS>:: Finite_vertices_iterator</code>		A type for an iterator over finite vertices.
<code>Segment_Delaunay_graph_2<Gt,DS>:: Finite_faces_iterator</code>		A type for an iterator over finite faces.
<code>Segment_Delaunay_graph_2<Gt,DS>:: Finite_edges_iterator</code>		A type for an iterator over finite edges.

In addition to iterators and circulators for vertices and faces, iterators for sites are provided. In particular there are iterators for the set of input sites and the set of output sites. The set of input sites is the set of sites inserted by the user using the *insert* methods of this class. If a site is inserted multiple times, every instance of this site will be reported. The set of output sites is the set of sites in the segment Delaunay graph. The value type of these iterators is *Site_2*.

<code>Segment_Delaunay_graph_2<Gt,DS>:: Input_sites_iterator</code>	A type for a bidirectional iterator over all input sites.
<code>Segment_Delaunay_graph_2<Gt,DS>:: Output_sites_iterator</code>	A type for a bidirectional iterator over all output sites (the sites in the Delaunay graph).

Creation

In addition to the default and copy constructors the following constructors are defined:

<code>Segment_Delaunay_graph_2<Gt,DS> sdg(Gt gt=Gt());</code>	Creates the segment Delaunay graph using <i>gt</i> as geometric traits.
--	---

`template< class Input_iterator >`

`Segment_Delaunay_graph_2<Gt,DS> sdg(Input_iterator first, Input_iterator beyond, Gt gt=Gt());`

Creates the segment Delaunay graph using *gt* as geometric traits and inserts all sites in the range [*first*, *beyond*).

Precondition: *Input_iterator* must be a model of *InputIterator*. The value type of *Input_iterator* must be either *Point_2* or *Site_2*.

Access Functions

<code>Geom_traits</code>	<code>sdg.geom_traits()</code>	Returns a reference to the segment Delaunay graph traits object.
--------------------------	--------------------------------	--

<i>int</i>	<i>sdg.dimension()</i>	Returns the dimension of the segment Delaunay graph. The dimension is -1 if the graph contains no sites, 0 if the graph contains one site, 1 if it contains two sites and 2 if it contains three or more sites.
<i>size_type</i>	<i>sdg.number_of_vertices()</i>	Returns the number of finite vertices of the segment Delaunay graph.
<i>size_type</i>	<i>sdg.number_of_faces()</i>	Returns the number of faces (both finite and infinite) of the segment Delaunay graph.
<i>size_type</i>	<i>sdg.number_of_input_sites()</i>	Return the number of input sites.
<i>size_type</i>	<i>sdg.number_of_output_sites()</i>	Return the number of output sites. This is equal to the number of vertices in the segment Delaunay graph.
<i>Face_handle</i>	<i>sdg.infinite_face()</i>	Returns a face incident to the <i>infinite_vertex</i> .
<i>Vertex_handle</i>	<i>sdg.infinite_vertex()</i>	Returns the <i>infinite_vertex</i> .
<i>Vertex_handle</i>	<i>sdg.finite_vertex()</i>	Returns a vertex distinct from the <i>infinite_vertex</i> . <i>Precondition:</i> The number of sites in the segment Delaunay graph must be at least one.
<i>Data_structure</i>	<i>sdg.data_structure()</i>	Returns a reference to the segment Delaunay graph data structure object.
<i>Data_structure</i>	<i>sdg.tds()</i>	Same as <i>data_structure()</i> . It has been added for compliance to the <i>DelaunayGraph_2</i> concept.
<i>Point_container</i>	<i>sdg.point_container()</i>	Returns a reference to the point container object.

Traversal of the segment Delaunay graph

A segment Delaunay graph can be seen as a container of faces and vertices. Therefore the *Segment_Delaunay_graph_2*<Gt,DS> class provides several iterators and circulators that allow to traverse it (completely or partially).

Face, Edge and Vertex Iterators

The following iterators allow respectively to visit finite faces, finite edges and finite vertices of the segment Delaunay graph. These iterators are non-mutable, bidirectional and their value types are respectively *Face*, *Edge* and *Vertex*. They are all invalidated by any change in the segment Delaunay graph.

<i>Finite_vertices_iterator</i>	<i>sdg.finite_vertices_begin()</i>	Starts at an arbitrary finite vertex.
<i>Finite_vertices_iterator</i>	<i>sdg.finite_vertices_end()</i>	Past-the-end iterator.
<i>Finite_edges_iterator</i>	<i>sdg.finite_edges_begin()</i>	Starts at an arbitrary finite edge.
<i>Finite_edges_iterator</i>	<i>sdg.finite_edges_end()</i>	Past-the-end iterator.
<i>Finite_faces_iterator</i>	<i>sdg.finite_faces_begin()</i>	Starts at an arbitrary finite face.
<i>Finite_faces_iterator</i>	<i>sdg.finite_faces_end()</i>	Past-the-end iterator.

The following iterators allow respectively to visit all (both finite and infinite) faces, edges and vertices of the segment Delaunay graph. These iterators are non-mutable, bidirectional and their value types are respectively *Face*, *Edge* and *Vertex*. They are all invalidated by any change in the segment Delaunay graph.

<i>All_vertices_iterator</i>	<i>sdg.all_vertices_begin()</i>	Starts at an arbitrary vertex.
<i>All_vertices_iterator</i>	<i>sdg.all_vertices_end()</i>	Past-the-end iterator.
<i>All_edges_iterator</i>	<i>sdg.all_edges_begin()</i>	Starts at an arbitrary edge.

<i>All_edges_iterator</i>	<i>sdg.all_edges_end()</i>	Past-the-end iterator.
---------------------------	----------------------------	------------------------

<i>All_faces_iterator</i>	<i>sdg.all_faces_begin()</i>	Starts at an arbitrary face.
<i>All_faces_iterator</i>	<i>sdg.all_faces_end()</i>	Past-the-end iterator.

Site iterators

The following iterators allow respectively to visit all sites. These iterators are non-mutable, bidirectional and their value type is *Site_2*. They are all invalidated by any change in the segment Delaunay graph.

<i>Input_sites_iterator</i>	<i>sdg.input_sites_begin()</i>	Starts at an arbitrary input site.
<i>Input_sites_iterator</i>	<i>sdg.input_sites_end()</i>	Past-the-end iterator.
<i>Output_sites_iterator</i>	<i>sdg.output_sites_begin()</i>	Starts at an arbitrary output site.
<i>Output_sites_iterator</i>	<i>sdg.output_sites_end()</i>	Past-the-end iterator.

Face, Edge and Vertex Circulators

The *Segment_Delaunay_graph_2*<*Gt,DS*> class also provides circulators that allow to visit respectively all faces or edges incident to a given vertex or all vertices adjacent to a given vertex. These circulators are non-mutable and bidirectional. The operator *operator++* moves the circulator counterclockwise around the vertex while the *operator--* moves clockwise. A face circulator is invalidated by any modification of the face pointed to. An edge circulator is invalidated by any modification in one of the two faces incident to the edge pointed to. A vertex circulator is invalidated by any modification in any of the faces adjacent to the vertex pointed to.

<i>Face_circulator</i>	<i>sdg.incident_faces(Vertex_handle v)</i>	
		Starts at an arbitrary face incident to <i>v</i> .
<i>Face_circulator</i>	<i>sdg.incident_faces(Vertex_handle v, Face_handle f)</i>	
		Starts at face <i>f</i> .
		<i>Precondition:</i> Face <i>f</i> is incident to vertex <i>v</i> .

<i>Edge_circulator</i>	<i>sdg.incident_edges(Vertex_handle v)</i>	
		Starts at an arbitrary edge incident to <i>v</i> .

<i>Edge_circulator</i>	<i>sdg.incident_edges(Vertex_handle v, Face_handle f)</i>	
		Starts at the first edge of <i>f</i> incident to <i>v</i> , in counterclockwise order around <i>v</i> .
		<i>Precondition:</i> Face <i>f</i> is incident to vertex <i>v</i> .

<i>Vertex_circulator</i>	<i>sdg.incident_vertices(Vertex_handle v)</i>	
		Starts at an arbitrary vertex incident to <i>v</i> .

<i>Vertex_circulator</i>	<i>sdg.incident_vertices(Vertex_handle v, Face_handle f)</i>	
		Starts at the first vertex of <i>f</i> adjacent to <i>v</i> in counterclockwise order around <i>v</i> .
		<i>Precondition:</i> Face <i>f</i> is incident to vertex <i>v</i> .

Traversal of the Convex Hull

Applied on the *infinite_vertex* the above methods allow to visit the vertices on the convex hull and the infinite edges and faces. Note that a counterclockwise traversal of the vertices adjacent to the *infinite_vertex* is a clockwise traversal of the convex hull.

```
Vertex_circulator    sdg.incident_vertices( sdg.infinite_vertex())
Vertex_circulator    sdg.incident_vertices( sdg.infinite_vertex(), Face_handle f)
Face_circulator      sdg.incident_faces( sdg.infinite_vertex())
Face_circulator      sdg.incident_faces( sdg.infinite_vertex(), Face_handle f)
Edge_circulator      sdg.incident_edges( sdg.infinite_vertex())
Edge_circulator      sdg.incident_edges( sdg.infinite_vertex(), Face_handle f)
```

Predicates

The class *Segment_Delaunay_graph_2*<*Gt,DS*> provides methods to test the finite or infinite character of any feature.

```
bool    sdg.is_infinite( Vertex_handle v)      true, iff v is the infinite_vertex.
bool    sdg.is_infinite( Face_handle f)        true, iff face f is infinite.
bool    sdg.is_infinite( Face_handle f, int i) true, iff edge (f,i) is infinite.
bool    sdg.is_infinite( Edge e)              true, iff edge e is infinite.
bool    sdg.is_infinite( Edge_circulator ec)   true, iff edge *ec is infinite.
```

Insertion

```
template< class Input_iterator >
size_type    sdg.insert( Input_iterator first, Input_iterator beyond)
```

Inserts the sites in the range [*first,beyond*). The number of additional sites inserted in the Delaunay graph is returned. *Input_iterator* must be a model of *InputIterator* and its value type must be either *Point_2* or *Site_2*.

```
template< class Input_iterator >
size_type    sdg.insert( Input_iterator first, Input_iterator beyond, Tag_false)
```

Same as the previous method. *Input_iterator* must be a model of *InputIterator* and its value type must be either *Point_2* or *Site_2*.

```
template< class Input_iterator >
size_type    sdg.insert( Input_iterator first, Input_iterator beyond, Tag_true)
```

Inserts the sites in the range [*first,beyond*) after performing a random shuffle on them. The number of additional sites inserted in the Delaunay graph is returned. *Input_iterator* must be a model of *InputIterator* and its value type must be either *Point_2* or *Site_2*.

```
Vertex_handle    sdg.insert( Point_2 p)
```

Inserts the point *p* in the segment Delaunay graph. If *p* has already been inserted, then the vertex handle of its already inserted copy is returned. If *p* has not been inserted yet, the vertex handle of *p* is returned.

Vertex_handle *sdg.insert(Point_2 p, Vertex_handle vnear)*

Inserts p in the segment Delaunay graph using the site associated with $vnear$ as an estimate for the nearest neighbor of p . The vertex handle returned has the same semantics as the vertex handle returned by the method *Vertex_handle insert(Point_2 p)*.

Vertex_handle *sdg.insert(Point_2 p1, Point_2 p2)*

Inserts the closed segment with endpoints $p1$ and $p2$ in the segment Delaunay graph. If the segment has already been inserted in the Delaunay graph then the vertex handle of its already inserted copy is returned. If the segment does not intersect any segment in the existing diagram, the vertex handle corresponding to its corresponding open segment is returned. Finally, if the segment intersects other segments in the existing Delaunay graph, the vertex handle to one of its open subsegments is returned.

Vertex_handle *sdg.insert(Point_2 p1, Point_2 p2, Vertex_handle vnear)*

Inserts the segment whose endpoints are $p1$ and $p2$ in the segment Delaunay graph using the site associated with $vnear$ as an estimate for the nearest neighbor of $p1$. The vertex handle returned has the same semantics as the vertex handle returned by the method *Vertex_handle insert(Point_2 p1, Point_2 p2)*.

Vertex_handle *sdg.insert(Site_2 s)*

Inserts the site s in the segment Delaunay graph. The vertex handle returned has the same semantics as the vertex handle returned by the methods *Vertex_handle insert(Point_2 p)* and *Vertex_handle insert(Point_2 p1, Point_2 p2)*, depending on whether s represents a point or a segment respectively.

Precondition: s.is_input() must be true.

Vertex_handle *sdg.insert(Site_2 s, Vertex_handle vnear)*

Inserts s in the segment Delaunay graph using the site associated with $vnear$ as an estimate for the nearest neighbor of s , if s is a point, or the first endpoint of s , if s is a segment. The vertex handle returned has the same semantics as the vertex handle returned by the method *Vertex_handle insert(Site_2 s)*.

Precondition: s.is_input() must be true.

Nearest neighbor location

Vertex_handle *sdg.nearest_neighbor(Point_2 p)*

Finds the nearest neighbor of the point p . In other words it finds the site whose segment Voronoi diagram cell contains p . Ties are broken arbitrarily and one of the nearest neighbors of p is returned. If there are no sites in the segment Delaunay graph *Vertex_handle()* is returned.

Vertex_handle *sdg.nearest_neighbor(Point_2 p, Vertex_handle vnear)*

Finds the nearest neighbor of the point p using the site associated with $vnear$ as an estimate for the nearest neighbor of p . Ties are broken arbitrarily and one of the nearest neighbors of p is returned. If there are no sites in the segment Delaunay graph *Vertex_handle()* is returned.

I/O

template < class Stream >
Stream& sdg.draw_dual(Stream& str) Draws the segment Voronoi diagram to the stream *str*. The following operators must be defined:

Stream& operator<<(Stream&, Gt::Segment_2)

Stream& operator<<(Stream&, Gt::Ray_2)

Stream& operator<<(Stream&, Gt::Line_2)

template < class Stream >
Stream& sdg.draw_skeleton(Stream& str)

Draws the segment Voronoi diagram to the stream *str*, except the edges of the diagram corresponding to a segment and its endpoints. The following operators must be defined:

Stream& operator<<(Stream&, Gt::Segment_2)

Stream& operator<<(Stream&, Gt::Ray_2)

Stream& operator<<(Stream&, Gt::Line_2)

template< class Stream >
Stream& sdg.draw_dual_edge(Edge e, Stream& str)

Draws the edge *e* of the segment Voronoi diagram to the stream *str*. The following operators must be defined:

Stream& operator<<(Stream&, Gt::Segment_2)

Stream& operator<<(Stream&, Gt::Ray_2)

Stream& operator<<(Stream&, Gt::Line_2)

Precondition: e must be a finite edge.

template< class Stream >
Stream& sdg.draw_dual_edge(Edge_circulator ec, Stream& str)

Draws the edge **ec* of the segment Voronoi diagram to the stream *str*. The following operators must be defined:

Stream& operator<<(Stream&, Gt::Segment_2)

Stream& operator<<(Stream&, Gt::Ray_2)

Stream& operator<<(Stream&, Gt::Line_2)

*Precondition: *ec must be a finite edge.*

template< class Stream >
Stream& sdg.draw_dual_edge(All_edges_iterator eit, Stream& str)

Draws the edge **eit* of the segment Voronoi diagram to the stream *str*. The following operators must be defined:

Stream& operator<<(Stream&, Gt::Segment_2)

Stream& operator<<(Stream&, Gt::Ray_2)

Stream& operator<<(Stream&, Gt::Line_2)

*Precondition: *eit must be a finite edge.*

template< class Stream >
Stream& sdg.draw_dual_edge(Finite_edges_iterator eit, Stream& str)

Draws the edge **eit* of the segment Voronoi diagram to the stream *str*. The following operators must be defined:

Stream& operator<<(Stream&, Gt::Segment_2)

Stream& operator<<(Stream&, Gt::Ray_2)

Stream& operator<<(Stream&, Gt::Line_2)

<code>void</code>	<code>sdg.file_output(std::ostream& os)</code>	Writes the current state of the segment Delaunay graph to an output stream. In particular, all sites in the diagram are written to the stream (represented through appropriate input sites), as well as the underlying combinatorial data structure.
<code>void</code>	<code>sdg.file_input(std::istream& is)</code>	Reads the state of the segment Delaunay graph from an input stream.
<code>std::ostream&</code>	<code>std::ostream& os << sdg</code>	Writes the current state of the segment Delaunay graph to an output stream.
<code>std::istream&</code>	<code>std::istream& is >> sdg</code>	Reads the state of the segment Delaunay graph from an input stream.

Validity check

<code>bool</code>	<code>sdg.is_valid(bool verbose = false, int level = 1)</code>	Checks the validity of the segment Delaunay graph. If <i>verbose</i> is <i>true</i> a short message is sent to <code>std::cerr</code> . If <i>level</i> is 0, only the data structure is validated. If <i>level</i> is 1, then both the data structure and the segment Delaunay graph are validated. Negative values of <i>level</i> always return true, and values greater than 1 are equivalent to <i>level</i> being 1.
-------------------	---	--

Miscellaneous

<code>void</code>	<code>sdg.clear()</code>	Clears all contents of the segment Delaunay graph.
<code>void</code>	<code>sdg.swap(other)</code>	The segment Delaunay graphs <i>other</i> and <i>sdg</i> are swapped. <code>sdg.swap(other)</code> should be preferred to <code>sdg= other</code> or to <code>sdg(other)</code> if <i>other</i> is deleted afterwards.

SegmentDelaunayGraphSite_2

Definition

The concept *SegmentDelaunayGraphSite_2* provides the requirements for the sites of a segment Delaunay graph.

Refines

DefaultConstructible

CopyConstructible

Assignable

Types

<i>SegmentDelaunayGraphSite_2:: Point_2</i>	The point type.
<i>SegmentDelaunayGraphSite_2:: Segment_2</i>	The segment type.
<i>SegmentDelaunayGraphSite_2:: FT</i>	The field number type.
<i>SegmentDelaunayGraphSite_2:: RT</i>	The ring number type.

Creation

In addition to the default and copy constructors the following static methods are available for constructing sites:

<i>SegmentDelaunayGraphSite_2</i>	<i>s.construct_site_2(Point_2 p)</i>	Constructs a site from a point: the site represents the point p .
<i>SegmentDelaunayGraphSite_2</i>	<i>s.construct_site_2(Point_2 p1, Point_2 p2)</i>	Constructs a site from two points: the site represents the (open) segment $(p1,p2)$.
<i>SegmentDelaunayGraphSite_2</i>	<i>s.construct_site_2(Point_2 p1, Point_2 p2, Point_2 q1, Point_2 q2)</i>	Constructs a site from four points: the site represents the point of intersection of the segments $(p1,p2)$ and $(q1,q2)$.
<i>SegmentDelaunayGraphSite_2</i>	<i>s.construct_site_2(Point_2 p1, Point_2 p2, Point_2 q1, Point_2 q2, bool b)</i>	Constructs a site from four points and a boolean: the site represents a segment. If b is <i>true</i> the endpoints are $p1$ and p_{\times} , otherwise p_{\times} and $p2$. p_{\times} is the point of intersection of the segments $(p1,p2),(q1,q2)$.
<i>SegmentDelaunayGraphSite_2</i>	<i>s.construct_site_2(Point_2 p1, Point_2 p2, Point_2 q1, Point_2 q2, Point_2 r1,</i>	

Point_2 r2)

Constructs a site from six points: the site represents the segment with endpoints the points of intersection of the pairs of segments $(p1,p2),(q1,q2)$ and $(p1,p2),(r1,r2)$.

Predicates

<i>bool</i>	<i>s.is_defined()</i>	Returns <i>true</i> if the site represents a valid point or segment.
<i>bool</i>	<i>s.is_point()</i>	Returns <i>true</i> if the site represents a point.
<i>bool</i>	<i>s.is_segment()</i>	Returns <i>true</i> if the site represents a segment.
<i>bool</i>	<i>s.is_input()</i>	Returns <i>true</i> if the site represents an input point or a segment defined by two input points. Returns <i>false</i> if it represents a point of intersection of two segments, or if it represents a segment, at least one endpoint of which is a point of intersection of two segments.
<i>bool</i>	<i>s.is_input(unsigned int i)</i>	Returns <i>true</i> if the <i>i</i> -th endpoint of the site is an input point. Returns <i>false</i> if the <i>i</i> -th endpoint of the site is the intersection of two segments. <i>Precondition:</i> <i>i</i> must be at most 1, and <i>s.is_segment()</i> must be <i>true</i> .

Access Functions

<i>Point_2</i>	<i>s.point()</i>	Returns the point represented by the site <i>s</i> . <i>Precondition:</i> <i>s.is_point()</i> must be <i>true</i> .
<i>Segment_2</i>	<i>s.segment()</i>	Returns the segment represented by the site <i>s</i> . <i>Precondition:</i> <i>s.is_segment()</i> must be <i>true</i> .
<i>Point_2</i>	<i>s.source()</i>	Returns the source endpoint of the segment. Note that this method can construct an inexact point if the number type used is inexact. <i>Precondition:</i> <i>s.is_segment()</i> must be <i>true</i> .
<i>Point_2</i>	<i>s.target()</i>	Returns the target endpoint of the segment. Note that this method can construct an inexact point if the number type used is inexact. <i>Precondition:</i> <i>s.is_segment()</i> must be <i>true</i> .
<i>SegmentDelaunayGraphSite_2</i>	<i>s.supporting_site()</i>	Returns a segment site object representing the segment that supports the segment represented by the site. Both endpoints of the returned site are input points. <i>Precondition:</i> <i>s.is_segment()</i> must be <i>true</i> .
<i>SegmentDelaunayGraphSite_2</i>	<i>s.supporting_site(unsigned int i)</i>	Returns a segment site object representing the <i>i</i> -th segment that supports the point of intersection represented by the site. Both endpoints of the returned site are input points. <i>Precondition:</i> <i>i</i> must be at most 1, <i>s.is_point()</i> must be <i>true</i> and <i>s.is_input()</i> must be <i>false</i> .
<i>SegmentDelaunayGraphSite_2</i>	<i>s.crossing_site(unsigned int i)</i>	Returns a segment site object representing the <i>i</i> -th segment that supports the <i>i</i> -th endpoint of the site which is not the supporting segment of the site. Both endpoints of the returned site are input points. <i>Precondition:</i> <i>i</i> must be at most 1, <i>s.is_segment()</i> must be <i>true</i> and <i>s.is_input(i)</i> must be <i>false</i> .

SegmentDelaunayGraphSite_2 *s.source_site()*

Returns a point site object representing the source point of the site.
Precondition: s.is_segment() must be *true*.

SegmentDelaunayGraphSite_2 *s.target_site()*

Returns a point site object representing the target point of the site.
Precondition: s.is_segment() must be *true*.

Point_2 *s.source_of_supporting_site()*

Returns the source point of the supporting site of the this site.
Precondition: is_segment() must be *true*.

Point_2 *s.target_of_supporting_site()*

Returns the target point of the supporting site of the this site.
Precondition: is_segment() must be *true*.

Point_2 *s.source_of_supporting_site(unsigned int i)*

Returns the source point of the *i*-th supporting site of the this site.
Precondition: is_point() must be *true*, *is_input()* must be *false* and *i* must either be 0 or 1.

Point_2 *s.target_of_supporting_site(unsigned int i)*

Returns the target point of the *i*-th supporting site of the this site.
Precondition: is_point() must be *true*, *is_input()* must be *false* and *i* must either be 0 or 1.

Point_2 *s.source_of_crossing_site(unsigned int i)*

Returns the source point of the *i*-th crossing site of the this site.
Precondition: is_segment() must be *true*, *is_input(i)* must be *false* and *i* must either be 0 or 1.

Point_2 *s.target_of_crossing_site(unsigned int i)*

Returns the target point of the *i*-th supporting site of the this site.
Precondition: is_segment() must be *true*, *is_input(i)* must be *false* and *i* must either be 0 or 1.

SegmentDelaunayGraphStorageSite_2

Definition

The concept *SegmentDelaunayGraphStorageSite_2* provides the requirements for the storage sites of a segment Delaunay graph. The storage sites are sites that are used to store the information of a site in a more compact form (that uses less storage). This is achieved by storing handles to points instead of points.

Refines

DefaultConstructible
CopyConstructible
Assignable

Types

<i>SegmentDelaunayGraphStorageSite_2:: Site_2</i>		The site type.
<i>typedef typename std::set<typename Site_2::Point_2>::iterator</i>	<i>Point_handle;</i>	The type for a handle to a point.

Creation

In addition to the default and copy constructors, the following static methods should be available for constructing sites:

<i>SegmentDelaunayGraphStorageSite_2</i>	<i>ss.construct_storage_site_2(Point_handle hp)</i>	Constructs a storage site from a point handle. The storage site represents the point associated with the point handle <i>hp</i> .
<i>SegmentDelaunayGraphStorageSite_2</i>	<i>ss.construct_storage_site_2(Point_handle hp1, Point_handle hp2)</i>	Constructs a storage site from two point handles. The storage site represents the segment the endpoints of which are the points associated with the point handles <i>hp1</i> and <i>hp2</i> .
<i>SegmentDelaunayGraphStorageSite_2</i>	<i>ss.construct_storage_site_2(Point_handle hp1, Point_handle hp2, Point_handle hq1, Point_handle hq2)</i>	Constructs a storage site from four point handles. The storage site represents the point of intersection of the segments the endpoints of which are the points associated with the point handles <i>hp1</i> , <i>hp2</i> and <i>hq1</i> and <i>hq2</i> , respectively.

```
SegmentDelaunayGraphStorageSite_2    ss.construct_storage_site_2( Point_handle hp1,
                                         Point_handle hp2,
                                         Point_handle hq1,
                                         Point_handle hq2,
                                         bool b)
```

Constructs a site from four point handles and a boolean. The storage site represents a segment. If *b* is *true*, the first endpoint of the segment is the point associated with the handle *hp1* and the second endpoint is the point of intersection of the segments the endpoints of which are the point associated with the point handles *hp1*, *hp2* and *hq1*, *hq2*, respectively. If *b* is *false*, the first endpoint of the represented segment is the one mentioned above, whereas the second endpoint if the point associated with the point handle *hp2*.

```
SegmentDelaunayGraphStorageSite_2    ss.construct_storage_site_2( Point_handle hp1,
                                         Point_handle hp2,
                                         Point_handle hq1,
                                         Point_handle hq2,
                                         Point_handle hr1,
                                         Point_handle hr2)
```

Constructs a storage site from six point handles. The storage site represents of segment the endpoints of which are points of intersection of two pairs of segments, the endpoints of which are $hp1$, $hp2/hq1$, $hq2$ and $hp1$, $hp2/hr1$, $hr2$, respectively.

Predicates

<i>bool</i>	<i>ss.is_defined()</i>	Returns <i>true</i> if the storage site represents a valid point or segment.
<i>bool</i>	<i>ss.is_point()</i>	Returns <i>true</i> if the storage site represents a point.
<i>bool</i>	<i>ss.is_segment()</i>	Returns <i>true</i> if the storage site represents a segment.
<i>bool</i>	<i>ss.is_input()</i>	Returns <i>true</i> if the storage site represents an input point or a segment defined by two input points. Returns <i>false</i> if it represents a point of intersection of two segments, or if it represents a segment, at least one endpoint of which is a point of intersection of two segments.
<i>bool</i>	<i>ss.is_input(unsigned int i)</i>	Returns <i>true</i> if the <i>i</i> -th endpoint of the corresponding site is an input point. Returns <i>false</i> if the <i>i</i> -th endpoint of the corresponding site is the intersection of two segments. <i>Precondition:</i> <i>i</i> must be at most 1, and <i>ss.is_segment()</i> must be <i>true</i> .

Access Functions

SegmentDelaunayGraphStorageSite_2 ss.supporting_site()

Returns a storage site object representing the segment that supports the segment represented by the storage site. The returned storage site represents a site, both endpoints of which are input points.

Precondition: `ss.is_segment()` must be *true*.

<i>SegmentDelaunayGraphStorageSite_2</i>	<i>ss.source_site()</i>	Returns a storage site that represents the first endpoint of the represented segment. <i>Precondition: ss.is_segment() must be true.</i>
<i>SegmentDelaunayGraphStorageSite_2</i>	<i>ss.target_site()</i>	Returns a storage site that represents the second endpoint of the represented segment. <i>Precondition: ss.is_segment() must be true.</i>
<i>SegmentDelaunayGraphStorageSite_2</i>	<i>ss.supporting_site(unsigned int i)</i>	Returns a storage site object representing the <i>i</i> -th segment that supports the point of intersection represented by the storage site. The returned storage site represents a site, both endpoints of which are input points. <i>Precondition: i must be at most 1, ss.is_point() must be true and ss.is_input() must be false.</i>
<i>SegmentDelaunayGraphStorageSite_2</i>	<i>ss.crossing_site(unsigned int i)</i>	Returns a storage site object representing the <i>i</i> -th segment that supports the <i>i</i> -th endpoint of the site which is not the supporting segment of the site. The returned storage site represents a site, both endpoints of which are input points. <i>Precondition: i must be at most 1, ss.is_segment() must be true and ss.is_input(i) must be false.</i>
<i>Site_2</i>	<i>ss.site()</i>	Returns the site represented by the storage site.
<i>Point_handle</i>	<i>ss.point()</i>	Returns a handle associated with the represented point. <i>Precondition: is_point() and is_input() must both be true.</i>
<i>Point_handle</i>	<i>ss.source_of_supporting_site()</i>	Returns a handle to the source point of the supporting site of the this site. <i>Precondition: is_segment() must be true.</i>
<i>Point_handle</i>	<i>ss.target_of_supporting_site()</i>	Returns a handle to the target point of the supporting site of the this site. <i>Precondition: is_segment() must be true.</i>
<i>Point_handle</i>	<i>ss.source_of_supporting_site(unsigned int i)</i>	Returns a handle to the source point of the <i>i</i> -th supporting site of the this site. <i>Precondition: is_point() must be true, is_input() must be false and i must either be 0 or 1.</i>
<i>Point_handle</i>	<i>ss.target_of_supporting_site(unsigned int i)</i>	Returns a handle to the target point of the <i>i</i> -th supporting site of the this site. <i>Precondition: is_point() must be true, is_input() must be false and i must either be 0 or 1.</i>

Point_handle

ss.source_of_crossing_site(unsigned int i)

Returns a handle to the source point of the *i*-th crossing site of the this site.

Precondition: *is_segment()* must be *true*, *is_input(i)* must be *false* and *i* must either be 0 or 1.

Point_handle

ss.target_of_crossing_site(unsigned int i)

Returns a handle to the target point of the *i*-th supporting site of the this site.

Precondition: *is_segment()* must be *true*, *is_input(i)* must be *false* and *i* must either be 0 or 1.

SegmentDelaunayGraphDataStructure_2

Definition

The concept *SegmentDelaunayGraphDataStructure_2* refines the concept *ApolloniusGraphDataStructure_2*. In addition it provides two methods for the merging of two vertices joined by an edge of the data structure, and the splitting of a vertex into two. The method that merges two vertices, called *join_vertices* identifies the two vertices and deletes their common two faces. The method that splits a vertex, called *split_vertex* introduces a new vertex that shares an edge and two faces with the old vertex (see figure below). Notice that the *join_vertices* and *split_vertex* operations are complementary, in the sense that one reverses the action of the other.

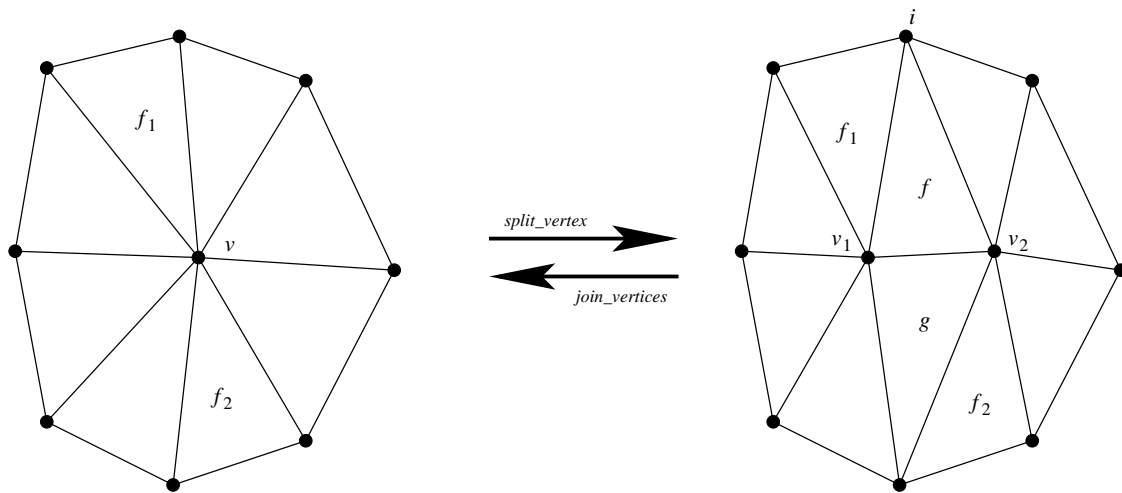

Figure 42.3: The join and split operations. Left to right: The vertex v is split into v_1 and v_2 . The faces f and g are inserted after f_1 and f_2 , respectively, in the counter-clockwise sense. The vertices v_1 , v_2 and the faces f and g are returned as a *boost tuple* in that order. Right to left: The edge (f, i) is collapsed, and thus the vertices v_1 and v_2 are joined. The vertex v is returned.

We only describe the additional requirements with respect to the *ApolloniusGraphDataStructure_2* concept.

Refines

ApolloniusGraphDataStructure_2

Modification

Vertex_handle `sdgds.join_vertices(Face_handle f, int i)` Joins the vertices that are endpoints of the edge (f, i) . It returns a vertex handle to common vertex.

boost::tuples::tuple<Vertex_handle, Vertex_handle, Face_handle, Face_handle>

sdgds.split_vertex(Vertex_handle v, Face_handle f1, Face_handle f2)

Splits the vertex v into two vertices $v1$ and $v2$. The common faces f and g of $v1$ and $v2$ are created after (in the counter-clockwise sense) the faces $f1$ and $f2$. The 4-tuple $(v1, v2, f, g)$ is returned (see Fig. [42.6](#)).

SegmentDelaunayGraphVertexBase_2

Definition

The concept *SegmentDelaunayGraphVertexBase_2* describes the requirements for the vertex base class of the *SegmentDelaunayGraphDataStructure_2* concept. A vertex stores a site of the segment Delaunay graph and provides access to one of its incident faces through a *Face_handle*.

Refines

DefaultConstructible
CopyConstructible
Assignable

Types

<i>SegmentDelaunayGraphVertexBase_2::Geom_traits</i>	A type for the geometric traits that defines the site. <i>Precondition:</i> The type <i>Geom_traits</i> must define the type <i>Site_2</i> .
<i>SegmentDelaunayGraphVertexBase_2::Site_2</i>	A type for the site. This type must coincide with the type <i>Geom_traits::Site_2</i> .
<i>SegmentDelaunayGraphVertexBase_2::Storage_site_tag</i>	A type that indicates what kind of storage type to use. <i>Storage_site_tag</i> must either be <i>CGAL::Tag_true</i> or <i>CGAL::Tag_false</i> .
<i>SegmentDelaunayGraphVertexBase_2::Storage_site_2</i>	A type for the internal representation of sites. This type must satisfy the requirements of the concept <i>SegmentDelaunayGraphStorageSite_2</i> .
<i>SegmentDelaunayGraphVertexBase_2::Data_structure</i>	A type for the underlying data structure, to which the vertex belongs to.
<i>SegmentDelaunayGraphVertexBase_2::Vertex_handle</i>	A type for the vertex handle of the segment Delaunay graph data structure.
<i>SegmentDelaunayGraphVertexBase_2::Face_handle</i>	A type for the face handle of the segment Delaunay graph data structure.

Creation

In addition to the default and copy constructors and following constructors are required:

<i>SegmentDelaunayGraphVertexBase_2</i> <i>v</i> (<i>Storage_site_2</i> <i>ss</i>);	Constructs a vertex associated with the site represented by the storage site <i>ss</i> .
<i>SegmentDelaunayGraphVertexBase_2</i> <i>v</i> (<i>Storage_site_2</i> <i>ss</i> , <i>Face_handle</i> <i>f</i>);	Constructs a vertex associated with the site represented by the storage site <i>ss</i> , and pointing to the face associated with the face handle <i>f</i> .

Access Functions

<i>Storage_site_2</i>	<i>v.storage_site()</i>	Returns the storage site representing the site.
<i>Site_2</i>	<i>v.site()</i>	Returns the site.
<i>Face_handle</i>	<i>v.face()</i>	Returns a handle to an incident face.

Setting

<i>void</i>	<i>v.set_site(Storage_site_2 ss)</i>	Sets the storage site.
<i>void</i>	<i>v.set_face(Face_handle f)</i>	Sets the incident face.

Checking

<i>bool</i>	<i>v.is_valid(bool verbose, int level)</i>	Performs any required tests on a vertex.

CGAL::Segment_Delaunay_graph_vertex_base_2<Gt,SSTag>

Definition

The class *Segment_Delaunay_graph_vertex_base_2<Gt,SSTag>* provides a model for the *SegmentDelaunayGraphVertexBase_2* concept which is the vertex base required by the *SegmentDelaunayGraphDataStructure_2* concept. The class *Segment_Delaunay_graph_vertex_base_2<Gt,SSTag>* has two template arguments, the first being the geometric traits of the segment Delaunay graph and should be a model of the concept *SegmentDelaunayGraphTraits_2*. The second template argument indicates whether or not to use the simple storage site that does not support intersecting segments, or the full storage site, that supports intersecting segments. The possible values are *CGAL::Tag_true* and *CGAL::Tag_false*. *CGAL::Tag_true* indicates that the full storage site is to be used, whereas *CGAL::Tag_false* indicates that the simple storage site is to be used.

SegmentDelaunayGraphTraits_2

Definition

The concept *SegmentDelaunayGraphTraits_2* provides the traits requirements for the *Segment_Delaunay_graph_2*<Gt,DS> and *Segment_Delaunay_graph_hierarchy_2*<Gt,STag,DS> classes. In particular, it provides a type *Site_2*, which must be a model of the concept *SegmentDelaunayGraphSite_2*. It also provides constructions for sites and several function object types for the predicates.

Refines

DefaultConstructible
CopyConstructible
Assignable

Types

<i>SegmentDelaunayGraphTraits_2:: Intersections_tag</i>	Indicates or not whether the intersecting segments are to be supported. The tag must either be <i>CGAL::Tag_true</i> or <i>CGAL::Tag_false</i> .
<i>SegmentDelaunayGraphTraits_2:: Site_2</i>	A type for a site of the segment Delaunay graph. Must be a model of the concept <i>SegmentDelaunayGraphSite_2</i> .
<i>SegmentDelaunayGraphTraits_2:: Point_2</i>	A type for a point.
<i>SegmentDelaunayGraphTraits_2:: Line_2</i>	A type for a line. Only required if the segment Delaunay graph is inserted in a stream.
<i>SegmentDelaunayGraphTraits_2:: Ray_2</i>	A type for a ray. Only required if the segment Delaunay graph is inserted in a stream.
<i>SegmentDelaunayGraphTraits_2:: Segment_2</i>	A type for a segment. Only required if if the segment Delaunay graph is inserted in a stream.
<i>SegmentDelaunayGraphTraits_2:: FT</i>	A type for the field number type of sites, points, etc..
<i>SegmentDelaunayGraphTraits_2:: RT</i>	A type for the ring number type of sites, points, etc.
<i>SegmentDelaunayGraphTraits_2:: Arrangement_type</i>	An enumeration type that indicates the type of the arrangement of two sites. The possible values are <i>DISJOINT</i> , <i>IDENTICAL</i> , <i>CROSSING</i> , <i>TOUCHING_1</i> , <i>TOUCHING_2</i> , <i>TOUCHING_11</i> , <i>TOUCHING_12</i> , <i>TOUCHING_21</i> , <i>TOUCHING_22</i> , <i>OVERLAPPING_11</i> , <i>OVERLAPPING_12</i> , <i>OVERLAPPING_21</i> , <i>OVERLAPPING_22</i> , <i>INTERIOR</i> , <i>INTERIOR_1</i> , <i>INTERIOR_2</i> , <i>TOUCHING_11_INTERIOR_1</i> , <i>TOUCHING_11_INTERIOR_2</i> , <i>TOUCHING_12_INTERIOR_1</i> , <i>TOUCHING_12_INTERIOR_2</i> , <i>TOUCHING_21_INTERIOR_1</i> , <i>TOUCHING_21_INTERIOR_2</i> , <i>TOUCHING_22_INTERIOR_1</i> , <i>TOUCHING_22_INTERIOR_2</i> . A detailed description of the meaning of these values is shown the end of the reference manual for this concept. (to be done)

<i>SegmentDelaunayGraphTraits_2:: Object_2</i>	A type representing different types of objects in two dimensions, namely: <i>Point_2</i> , <i>Site_2</i> , <i>Line_2</i> , <i>Ray_2</i> and <i>Segment_2</i> .
<i>SegmentDelaunayGraphTraits_2:: Assign_2</i>	Must provide <i>template <class T> bool operator() (T& t, Object_2 o)</i> which assigns <i>o</i> to <i>t</i> if <i>o</i> was constructed from an object of type <i>T</i> . Returns <i>true</i> , if the assignment was possible.
<i>SegmentDelaunayGraphTraits_2:: Construct_object_2</i>	Must provide <i>template <class T> Object_2 operator()(T t)</i> that constructs an object of type <i>Object_2</i> that contains <i>t</i> and returns it.
<i>SegmentDelaunayGraphTraits_2:: Construct_svd_vertex_2</i>	A constructor for a point of the segment Voronoi diagram equidistant from three sites. Must provide <i>Point_2 operator()(Site_2 s1, Site_2 s2, Site_2 s3)</i> , which constructs a point equidistant from the sites <i>s1</i> , <i>s2</i> and <i>s3</i> .
<i>SegmentDelaunayGraphTraits_2:: Compare_x_2</i>	A predicate object type. Must provide <i>Comparison_result operator()(Site_2 s1, Site_2 s2)</i> , which compares the x-coordinates of the points represented by the sites <i>s1</i> and <i>s2</i> . <i>Precondition: s1 and s2 must be points.</i>
<i>SegmentDelaunayGraphTraits_2:: Compare_y_2</i>	A predicate object type. Must provide <i>Comparison_result operator()(Site_2 s1, Site_2 s2)</i> , which compares the y-coordinates of the points represented by the sites <i>s1</i> and <i>s2</i> . <i>Precondition: s1 and s2 must be points.</i>
<i>SegmentDelaunayGraphTraits_2:: Orientation_2</i>	A predicate object type. Must provide <i>Orientation operator()(Site_2 s1, Site_2 s2, Site_2 s3)</i> , which performs the usual orientation test for three points. <i>s1</i> , <i>s2</i> and <i>s3</i> . <i>Precondition: the sites s1, s2 and s3 must be points.</i>
<i>SegmentDelaunayGraphTraits_2:: Equal_2</i>	A predicate object type. Must provide <i>bool operator()(Site_2 s1, Site_2 s2)</i> , which determines if the points represented by the sites <i>s1</i> and <i>s2</i> are identical. <i>Precondition: s1 and s2 must be points.</i>
<i>SegmentDelaunayGraphTraits_2:: Are_parallel_2</i>	A predicate object type. Must provide <i>bool operator()(Site_2 s1, Site_2 s2)</i> , which determines if the segments represented by the sites <i>s1</i> and <i>s2</i> are parallel. <i>Precondition: s1 and s2 must be segments.</i>
<i>SegmentDelaunayGraphTraits_2:: Oriented_side_of_bisector_2</i>	A predicate object type. Must provide <i>Oriented_side operator()(Site_2 s1, Site_2 s2, Point_2 p)</i> , which returns the oriented side of the bisector of <i>s1</i> and <i>s2</i> that contains <i>p</i> . Returns <i>ON_POSITIVE_SIDE</i> if <i>p</i> lies in the half-space of <i>s1</i> (i.e., <i>p</i> is closer to <i>s1</i> than <i>s2</i>); returns <i>ON_NEGATIVE_SIDE</i> if <i>p</i> lies in the half-space of <i>s2</i> ; returns <i>ON_ORIENTED_BOUNDARY</i> if <i>p</i> lies on the bisector of <i>s1</i> and <i>s2</i> .

SegmentDelaunayGraphTraits_2:: Vertex_conflict_2

A predicate object type. Must provide *Sign operator()(Site_2 s1, Site_2 s2, Site_2 s3, Site_2 q)*, which returns the sign of the distance of q from the Voronoi circle of $s1, s2, s3$ (the Voronoi circle of three sites $s1, s2, s3$ is a circle co-tangent to all three sites, that touches them in that order as we walk on its circumference in the counter-clockwise sense).

Precondition: the Voronoi circle of $s1, s2, s3$ must exist.

Must also provide *Sign operator()(Site_2 s1, Site_2 s2, Site_2 q)*, which returns the sign of the distance of q from the bitangent line of $s1, s2$ (a degenerate Voronoi circle, with its center at infinity).

SegmentDelaunayGraphTraits_2:: Finite_edge_interior_conflict_2

A predicate object type. Must provide *bool operator()(Site_2 s1, Site_2 s2, Site_2 s3, Site_2 s4, Site_2 q, Sign sgn)*. The sites $s1, s2, s3$ and $s4$ define a Voronoi edge that lies on the bisector of $s1$ and $s2$ and has as endpoints the Voronoi vertices defined by the triplets $s1, s2, s3$ and $s1, s4$ and $s2$. The sign sgn is the common sign of the distance of the site q from the Voronoi circle of the triplets $s1, s2, s3$ and $s1, s4$ and $s2$. In case that sgn is equal to *NEGATIVE*, the predicate returns *true* if and only if the entire Voronoi edge is in conflict with q . If sgn is equal to *POSITIVE* or *ZERO*, the predicate returns *false* if and only if q is not in conflict with the Voronoi edge.

Precondition: the Voronoi vertices of $s1, s2, s3$, and $s1, s4, s2$ must exist.

Must also provide *bool operator()(Site_2 s1, Site_2 s2, Site_2 s3, Site_2 q, Sign sgn)*. The sites $s1, s2, s3$ and the site at infinity s_∞ define a Voronoi edge that lies on the bisector of $s1$ and $s2$ and has as endpoints the Voronoi vertices v_{123} and $v_{1\infty 2}$ defined by the triplets $s1, s2, s3$ and $s1, s_\infty$ and $s2$ (the second vertex is actually at infinity). The sign sgn is the common sign of the distance of the site q from the two Voronoi circles centered at the Voronoi vertices v_{123} and $v_{1\infty 2}$. In case that sgn is *NEGATIVE*, the predicate returns *true* if and only if the entire Voronoi edge is in conflict with q . If sgn is *POSITIVE* or *ZERO*, the predicate returns *false* if and only if q is not in conflict with the Voronoi edge.

Precondition: the Voronoi vertex v_{123} of $s1, s2, s3$ must exist.

Must finally provide *bool operator()(Site_2 s1, Site_2 s2, Site_2 q, Sign sgn)*. The sites $s1, s2$ and the site at infinity s_∞ define a Voronoi edge that lies on the bisector of $v_{12\infty}$ and $v_{1\infty 2}$ $s1$ and $s2$ and has as endpoints the Voronoi vertices defined by the triplets $s1, s2, s_\infty$ and $s1, s_\infty$ and $s2$ (both vertices are actually at infinity). The sign sgn denotes the common sign of the distance of the site q from the Voronoi circles centered at $v_{12\infty}$ and $v_{1\infty 2}$. If sgn is *NEGATIVE*, the predicate returns *true* if and only if the entire Voronoi edge is in conflict with q . If *POSITIVE* or *ZERO* is *false*, the predicate returns *false* if and only if q is not in conflict with the Voronoi edge.

SegmentDelaunayGraphTraits_2:: Infinite_edge_interior_conflict_2

A predicate object type. Must provide *bool operator()(Site_2 s1, Site_2 s2, Site_2 s3, Site_2 q, Sign sgn)*. The sites $s_\infty, s1, s2$ and $s3$ define a Voronoi edge that lies on the bisector of s_∞ and $s1$ and has as endpoints the Voronoi vertices $v_{\infty 12}$ and $v_{\infty 31}$ defined by the triplets $s_\infty, s1, s2$ and $s_\infty, s3$ and $s1$. The sign sgn is the common sign of the distances of q from the Voronoi circles centered at the vertices $v_{\infty 12}$ and $v_{\infty 31}$. If sgn is *NEGATIVE*, the predicate returns *true* if and only if the entire Voronoi edge is in conflict with q . If sgn is *POSITIVE* or *ZERO*, the predicate returns *false* if and only if q is not in conflict with the Voronoi edge.

SegmentDelaunayGraphTraits_2:: Oriented_side_2

A predicate object type. Must provide *Oriented_side operator()(Site_1 s1, Site_2 s2, Site_2 s3, Site_2 s, Site_2 p)*. Determines the oriented side of the line ℓ that contains the point site p , where ℓ is the line that passes through the Voronoi vertex of the sites $s1, s2, s3$ and is perpendicular to the segment site s .

Precondition: s must be a segment and p must be a point.

SegmentDelaunayGraphTraits_2:: Arrangement_type_2

A predicate object type. Must provide *Arrangement_type operator()(Site_2 s1, Site_2 s2)* that returns the type of the arrangement of the two sites $s1$ and $s2$.

CGAL::Segment_Delaunay_graph_traits_2<K,MTag>

Definition

The class *Segment_Delaunay_graph_traits_2<K,MTag>* provides a model for the *SegmentDelaunayGraphTraits_2* concept. This class has two template parameters. The first template parameter must be a model of the *Kernel* concept. The second template parameter corresponds to how predicates are evaluated. There are two possible values for *MTag*, namely *CGAL::Field_with_sqrt_tag* and *CGAL::Field_tag*. The first one must be used when the number type used in the representation supports the exact evaluation of signs of expressions involving all four basic operations and square roots, whereas the second one requires the exact evaluation of signs of field-type expressions, i.e., expressions involving additions, subtractions, multiplications and divisions. The default value for *MTag* is *CGAL::Field_tag*. The way the predicates are evaluated is discussed in [Bur96] and [Kar04] (the geometric filtering part).

CGAL::Segment_Delaunay_graph_filtered_traits_2<CK,CM,EK,EM,FK,FM>

Definition

The class *Segment_Delaunay_graph_filtered_traits_2*<CK,CM,EK,EM,FK,FM> provides a model for the *SegmentDelaunayGraphTraits_2* concept.

The class *Segment_Delaunay_graph_filtered_traits_2*<CK,CM,EK,EM,FK,FM> uses the filtering technique [BBP01] to achieve traits for the *Segment_Delaunay_graph_2*<Gt,DS> class with efficient and exact predicates given an exact kernel *EK* and a filtering kernel *FK*. The geometric constructions associated provided by this class are equivalent to those provided by the traits class *Segment_Delaunay_graph_traits_2*<CK,CM>, which means that they may be inexact depending on the choice of the *CK* kernel.

This class has six template parameters. The first, third and fifth template parameters must be a models of the *Kernel* concept. The parameter *CK* is the construction kernel and it is the kernel that will be used for constructions. The parameter *FK* is the filtering kernel; this kernel will be used for performing the arithmetic filtering for the predicates involved in the computation of the segment Delaunay graph. Finally, the parameter *EK* is the exact kernel; this kernel will be used for computing the predicates if the filtering kernel fails to produce an answer.

The second, fourth and sixth template parameters correspond to how predicates are evaluated. There are two predefined possible values for these parameters, namely *CGAL::Field_with_sqrt_tag* and *CGAL::Field_tag*. The first one must be used when the number type used in the representation supports the exact evaluation of signs of expressions involving all four basic operations and square roots, whereas the second one requires that only field operations are exact. Finally, in order to get exact constructions *CM* must be set to *CGAL::Field_with_sqrt_tag* and the number type in *CK* must support operations involving divisions and square roots (as well as the other three basic operations of course). The way the predicates are evaluated is discussed in [Bur96] and [Kar04] (the geometric filtering part).

The default values for the template parameters are as follows: *CM* = *CGAL::Field_with_sqrt_tag* (it is assumed that *CGAL::Cartesian<double>* or *CGAL::Simple_cartesian<double>* will be the entry for the template parameter *CK*), *EM* = *CGAL::Field_tag*, *FK* = *CGAL::Simple_cartesian<CGAL::Interval_nt<false>>*, *FM* = *CGAL::Field_with_sqrt_tag*. If the GMP package is installed with CGAL, the template parameter *EK* has the default value: *EK* = *CGAL::Simple_cartesian<CGAL::Gmpq>*, otherwise its default value is *EK* = *CGAL::Simple_cartesian<CGAL::Quotient<CGAL::MP_Float>>*.

CGAL::Segment_Delaunay_graph_hierarchy_2<Gt,STag,DS>

Definition

We provide an alternative to the class *Segment_Delaunay_graph_2<Gt,DS>* for the incremental construction of the segment Delaunay graph. The *Segment_Delaunay_graph_hierarchy_2<Gt,STag,DS>* class maintains a hierarchy of Delaunay graphs. There are two possibilities as to how this hierarchy is constructed.

In the first case the bottom-most level of the hierarchy contains the full segment Delaunay graph. The upper levels of the hierarchy contain only points that are either point sites or endpoints of segment sites in the bottom-most Delaunay graph. A point that is in level i (either as an individual point or as the endpoint of a segment), is inserted in level $i + 1$ with probability $1/\alpha$ where $\alpha > 1$ is some constant. In the second case the upper levels of the hierarchy contains not only points but also segments. A site that is in level i , is in level $i + 1$ with probability $1/\beta$ where $\beta > 1$ is some constant.

The difference between the *Segment_Delaunay_graph_2<Gt,DS>* class and the *Segment_Delaunay_graph_hierarchy_2<Gt,STag,DS>* class (both versions of it) is on how the nearest neighbor location is done. Given a point p the location is done as follows: at the top most level we find the nearest neighbor of p as in the *Segment_Delaunay_graph_2<Gt,DS>* class. At every subsequent level i we use the nearest neighbor found at level $i + 1$ to find the nearest neighbor at level i . This is a variant of the corresponding hierarchy for points found in [Dev02]. The details are described in [Kar04].

The class has three template parameters. The first and third have essentially the same semantics as in the *Segment_Delaunay_graph_2<Gt,DS>* class. The first template parameter must be a model of the *SegmentDelaunayGraphTraits_2* concept. The third template parameter must be a model of the *SegmentDelaunayGraphDataStructure_2* concept. However, the vertex base class that is to be used in the segment Delaunay graph data structure must be a model of the *SegmentDelaunayGraphHierarchyVertexBase_2* concept. The third template parameter defaults to *Triangulation_data_structure_2<Segment_Delaunay_graph_hierarchy_vertex_base_2<Segment_Delaunay_graph_vertex_base_2<Gt>>, Triangulation_face_base_2<Gt>>*. The second template parameter controls whether or not segments are added in the upper levels of the hierarchy. It's possible values are *CGAL::Tag_true* and *CGAL::Tag_false*. If it is set to *CGAL::Tag_true*, segments are also inserted in the upper levels of the hierarchy. The value *CGAL::Tag_false* indicates that only points are to be inserted in the upper levels of the hierarchy. The default value for the second template parameter is *CGAL::Tag_false*.

The *Segment_Delaunay_graph_hierarchy_2<Gt,STag,DS>* class derives publicly from the *Segment_Delaunay_graph_2<Gt,DS>* class. The interface is the same with its base class. In the sequel only additional types and methods defined are documented.

CGAL::Segment_Delaunay_graph_2<Gt,DS>

Types

Segment_Delaunay_graph_hierarchy_2<*Gt*,*S**Tag*,*DS*> introduces the following types in addition to those introduced by its base class *Segment_Delaunay_graph_2*<*Gt*,*DS*>.

```
typedef STag                               Segments_in_hierarchy_tag;  
                                           A type for the STag template parameter.  
typedef CGAL::Segment_Delaunay_graph_2<Gt,DS> Base;    A type for the base class.
```

Creation

In addition to the default and copy constructors, the following constructors are defined:

```
Segment_Delaunay_graph_hierarchy_2<Gt,STag,DS> sdgh( Gt gt=Gt() );  
                                           Creates a hierarchy of segment Delaunay graphs using gt as geometric  
                                           traits.  
template< class Input_iterator >  
Segment_Delaunay_graph_hierarchy_2<Gt,STag,DS> sdgh( Input_iterator first,  
                                           Input_iterator beyond,  
                                           Gt gt=Gt() )  
                                           Creates a segment Delaunay graph hierarchy using gt as geometric  
                                           traits and inserts all sites in the range [first, beyond). Input_iterator  
                                           must be a model of InputIterator. The value type of Input_iterator  
                                           must be either Point_2 or Site_2.
```

I/O

```
std::ostream&    std::ostream& os << svdh    Writes the current state of the segment Delaunay graph hierar-  
                                                    chy to an output stream. In particular, all sites in the diagram  
                                                    are written to the stream (represented through appropriate in-  
                                                    put sites), as well as the underlying combinatorial hierarchical  
                                                    data structure.  
std::istream&    std::istream& is >> svdh    Reads the state of the segment Delaunay graph hierarchy from  
                                                    an input stream.

SegmentDelaunayGraphHierarchyVertexBase_2

Definition

The vertex of a segment Delaunay graph included in a segment Delaunay graph hierarchy has to provide some pointers to the corresponding vertices in the graphs of the next and preceeding levels. Therefore, the concept *SegmentDelaunayGraphHierarchyVertexBase_2* refines the concept *SegmentDelaunayGraphVertexBase_2*, by adding two vertex handles to the corresponding vertices for the next and previous level graphs.

Refines

SegmentDelaunayGraphVertexBase_2

Types

SegmentDelaunayGraphHierarchyVertexBase_2 does not introduce any types in addition to those of *SegmentDelaunayGraphVertexBase_2*.

Creation

The *SegmentDelaunayGraphHierarchyVertexBase_2* concept does not introduce any constructors in addition to those of the *SegmentDelaunayGraphVertexBase_2* concept.

Operations

<i>Vertex_handle</i>	<i>v.up()</i>	Returns a handle to the corresponding vertex of the next level segment Delaunay graph. If such a vertex does not exist <i>Vertex_handle()</i> is returned.
<i>Vertex_handle</i>	<i>v.down()</i>	Returns a handle to the corresponding vertex of the previous level segment Delaunay graph. If such a vertex does not exist <i>Vertex_handle()</i> is returned.
<i>void</i>	<i>v.set_up(Vertex_handle u)</i>	Sets the handle for the vertex of the next level segment Delaunay graph.
<i>void</i>	<i>v.set_down(Vertex_handle d)</i>	Sets the handle for the vertex of the previous level segment Delaunay graph.

This chapter describes the two-dimensional Apollonius graph of CGAL. We start with a few definitions in Section [43.1](#). The software design of the 2D Apollonius graph package is described in Section [43.2](#). In Section [43.3](#) we discuss the geometric traits of the 2D Apollonius graph package and in Section [43.4](#) the Apollonius graph hierarchy, a data structure suitable for fast nearest neighbor queries, is briefly described.

43.1 Definitions

The 2D Apollonius graph class of CGAL is designed to compute the dual of the *Apollonius diagram* or, as it is also known, the *Additively weighted Voronoi diagram*. The algorithm that has been implemented is dynamic, which means that we can perform insertions and deletions on line. The corresponding CGAL class is called `Apollonius_graph_2<ApolloniusGraphTraits_2, ApolloniusGraphDataStructure_2>` and will be discussed in more detail in the sequel. The interested reader may want to refer to the paper by Karavelas and Yvinec [[KY02](#)] for the general idea as well as the details of the algorithm implemented.

Before describing the details of the implementation we make a brief introduction to the theory of Apollonius diagrams. The Apollonius diagram is defined over a set of sites $P_i = (c_i, w_i)$, $i = 1, \dots, n$, where c_i is the point

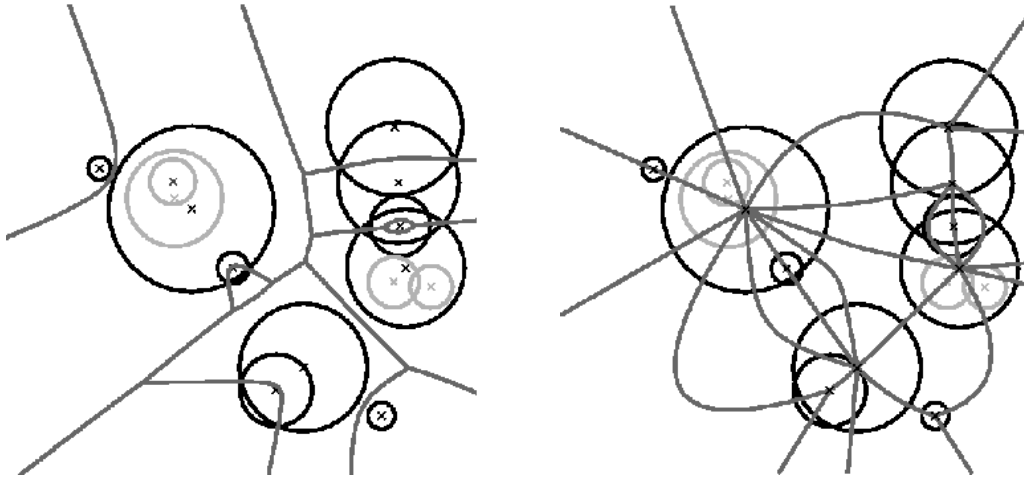

Figure 43.1: The Apollonius diagram (left) and its dual the Apollonius graph (right).

and w_i the weight of P_i . It is a subdivision of the plane into connected regions, called *cells*, associated with the sites (see Fig. 43.1(left)). The cell of a site P_i is the locus of points on the plane that are closer to P_i than any other site P_j , $j \neq i$. The distance $\delta(x, P_i)$ of a point x in the plane to a site P_i is defined as:

$$\delta(x, P_i) = \|x - c_i\| - w_i,$$

where $\|\cdot\|$ denotes the Euclidean norm. It can easily be seen that it is a generalization of the Voronoi diagram for points, which can actually be obtained if all the weights w_i are equal. Unlike the case of points, however, it is possible that a site P_i might have an empty cell. This can also happen in the case of the power diagram, whose dual is the regular triangulation (see Section 35.6). If this is the case we call the site *hidden* (these are the black circles in Fig. 43.1). A site which is not hidden will be referred to as *visible*.

If all weights w_i are non-negative, the Apollonius diagram can be viewed as the Voronoi diagram of the set of circles $\{P_1, \dots, P_n\}$, where c_i is the center of the circle P_i and w_i its radius. If the weights are allowed to be negative, we need to go to 3D in order to explain what the Apollonius diagram means geometrically. We identify the 2D Euclidean plane with the xy -plane in 3D. Then the Voronoi diagram of a set of points can be seen as the vertical projection on the xy -plane of the lower envelope of a set of 3D cones defined as follows: for each point p in the set of 2D points we have a cone C_p whose apex is the point p . The axis of C_p is a line parallel to the z -axis passing through p , the angle of C_p is 45° and, finally C_p is facing in the positive z -direction (that is, C_p is contained in the positive z -halfspace). The Apollonius diagram corresponds to shifting the apexes of these cones in the z -direction by a quantity equal to the weight. Sites with negative weight will give rise to cones whose apex is in the negative z -halfspace and sites with positive weight will give rise to cones whose apex is in the positive z -halfspace. In a manner analogous to the case of points, the Apollonius diagram can then be defined as the vertical projection on the xy -plane of the lower envelope of the set of shifted cones. Notice that when all apexes are translated along the z -direction by the same amount, the projection of the lower envelope of the set of cones does not change. In particular, we can translate all cones by a large enough amount so that all apexes are in the positive z -halfspace. Algebraically, this means that the Apollonius diagram does not change if we add to all weights the same quantity, which in particular, implies that we can assume without loss of generality that all weights are positive. Given the observations above and in order to simplify our discussion of Apollonius diagrams, we will, from now on, assume that all weights are positive, and we will refer to the sites as circles.

The Apollonius diagram is a planar graph, and so is its dual, the Apollonius graph. There are many ways to embed it on the plane and one such way is shown in Fig. 43.1(right). The Apollonius graph is uniquely defined once we have the Apollonius diagram. If the circles are in *general position* (see precise definition below),

then the Apollonius graph is a graph with triangular faces away from the convex hull of the set of circles (by triangular we mean that every face has exactly three edges). Near the convex hull we may have some spikes (i.e., vertices of degree 1). To unify our approach and handling of the Apollonius graph we add to the set of (finite) circles a fictitious circle at infinity, which we call the *site at infinity*. We can then connect all vertices of the outer face of the Apollonius graph to the site at infinity which gives us a graph with the property that all of its faces are now triangular. However, the Apollonius graph is not a triangulation for two main reasons: we cannot always embed it on the plane with straight line segments that yield a triangulation and, moreover, we may have two faces of the graph that have two edges in common, which is not allowed in a triangulation. Both of these particularities appear when we consider the Apollonius graph of the set of circles in Fig. 43.1(right).

We would like to finish our brief introduction to the theory of Apollonius graphs by discussing the concept of general position. We say that a set of circles is in general position if no two triplets of circles have the same tritangent circle. This statement is rather technical and it is best understood in the context of points. The equivalent statement for points is that we have no two triplets of points that define the same circumcircle, or equivalently that no four points are co-circular. The statement about general position made above is a direct generalization of the (much simpler to understand) statement about points. On the contrary, when we have circles in degenerate position, the Apollonius graph has faces with more than three edges on their boundary. We can get a triangulated version of the graph by simply *triangulating* the corresponding faces in an arbitrary way. In fact the algorithm that has been implemented in CGAL has the property that it always returns a valid *triangulated* version of the Apollonius graph. By valid we mean that it contains the actual Apollonius graph (i.e., the actual dual of the Apollonius diagram) and whenever there are faces with more than three faces then they are triangulated. The way that they are triangulated depends on the order of insertion and deletion of the circles in the diagram.

One final point has to be made about hidden circles. First of all we would like to be more precise about our definition of hidden circles: we say that a circle is hidden if its cell has empty interior. This definition allows us to guarantee that all visible circles have cells that are two-dimensional regions. Geometrically the fact that a circle is hidden means that it is contained in the closure of the disk of another circle (see again Fig. 43.1). Note that a circle contained in the union of several disks, but not in the closure of any one of them, is not hidden.

Hidden circles pose an additional difficulty to our algorithm and software design. Since we allow circles to be inserted and deleted at wish, it is possible that a circle that was hidden at some point in time, may become visible at a later point in time; for example this can happen if we delete the circle that hides it. For this purpose we store hidden circles and have them reappear when they become visible. We will discuss this issue in detail below. For the time being it suffices to say that the user has the ability to control this behavior. More specifically it is possible to discard the circles that become hidden. This choice is totally natural when for example we expect to do only insertions, since in this case a circle that becomes hidden will never reappear. On the other hand if deletions are expected as well, then we lose the ability to have the hidden circles reappear.

Degenerate Dimensions. The dimension of the Apollonius graph is in general 2. The exceptions to this rule are as follows:

- The dimension is -1 if the Apollonius graph contains no circles.
- The dimension is 0 if the Apollonius graph contains exactly one visible circle.
- The dimension is 1 if the Apollonius graph contains exactly two visible circles.

43.2 Software Design

The 2D Apollonius graph class `Apollonius_graph_2<ApolloniusGraphTraits_2, ApolloniusGraphDataStructure_2>` follows the design of the triangulation package of CGAL. It is

parametrized by two arguments:

- the **geometric traits** class. It provides the basic geometric objects involved in the algorithm, such as sites, points etc. It also provides the geometric predicates for the computation of the Apollonius graph, as well as some basic constructions that can be used, for example, to visualize the Apollonius graph or the Apollonius diagram. The geometric traits for the Apollonius graph will be discussed in more detail in the next section.
- the **Apollonius graph data structure**. This is essentially the same as the triangulation data structure (discussed in Chapter 36), augmented with some additional operations that are specific to Apollonius graphs. The corresponding concept is that of *ApolloniusGraphDataStructure_2*, which in fact is a refinement of the *TriangulationDataStructure_2* concept. The class *Triangulation_data_structure_2<Vb,Fb>* is a model of the concept *ApolloniusGraphDataStructure_2*. A default value for the corresponding template parameter is provided, so the user does not need to specify it.

Storing Hidden Sites. As we have already mentioned a circle is hidden if it is contained inside some visible circle. This creates a parent-child relationship between visible and hidden circles: the parent of a hidden circle is the visible circle that contains it. If more than one visible circles contain a hidden circle then the hidden circle can be assigned to any of the visible circles arbitrarily.

To store hidden circles we assign to every visible circle a list. This list comprises the hidden circles that are contained in the visible circle. The user can access the hidden circles associated with a visible circle through an iterator called *Hidden_sites_iterator*. This iterator is defined in the *ApolloniusGraphVertexBase_2* concept and is implemented by its model, the *Apollonius_graph_vertex_base_2<Gt,StoreHidden>* class. It is also possible to iterate through the entire set of hidden sites using an homonymous iterator defined by the *Apollonius_graph_2<Gt,Agds>* class.

Since storing hidden sites may not be of interest in some cases (e.g., for example this is the case if we only perform insertions in the Apollonius graph), the user has the possibility of controlling this behavior. More precisely, the class *Apollonius_graph_vertex_base_2<Gt,StoreHidden>* has two template parameters, the second of which is a Boolean value. This value is by default *true* and it indicates that hidden sites should be stored. The user can indicate that hidden sites may be discarded by setting this value to *false*.

43.3 The Geometric Traits

The predicates required for the computation of the Apollonius graph are rather complicated. It is not the purpose of this document to discuss them in detail. The interested reader may refer to the papers by Karavelas and Emiris for the details [KE02, KE03]. However, we would like to give a brief overview of what they compute. There are several predicates needed by this algorithm. We will discuss the most important/complicated ones. It turns out that it is much easier to describe them in terms of the Apollonius diagram, rather than the Apollonius graph. Whenever it is applicable we will also describe their meaning in terms of the Apollonius graph.

The first two geometric predicates are called *Is_hidden_2* and *Oriented_side_of_bisector_2*. The first one involves two circles, say P_1 and P_2 . It determines if P_1 is hidden with respect to P_2 ; more precisely it checks whether the circle P_1 is contained in the closure of the disk defined by the circle P_2 . As its name indicates, it determines if a circle is hidden or not. The second predicate involves two circles P_1 and P_2 and a point q . It answers the question whether q is closer to P_1 or P_2 . Its name stems from the fact that answering the aforementioned question is equivalent to determining the oriented side of the bisector of P_1 and P_2 that contains the query point q . This predicate is used by the algorithm for closest neighbor queries for points.

The next geometric predicate is called *Vertex_conflict_2* and it involves four circles P_1 , P_2 , P_3 , and P_4 (see Fig. 43.3). The first three (red circles in Fig. 43.3) define a tritangent circle (yellow circle in Fig. 43.3). What we

want to determine is the sign of the distance of the green circle from the yellow circle. The distance between two circles $K_1 = (c_1, r_1)$ and $K_2 = (c_2, r_2)$ is defined as the distance of their centers minus their radii:

$$\delta(K_1, K_2) = \|c_1 - c_2\| - r_1 - r_2.$$

This predicate determines if a vertex in the Apollonius diagram (the center of the yellow circle) is destroyed when a new circle is inserted in the diagram (the green circle). In the Apollonius graph it tells us if a triangular face of the diagram is to be destroyed or not.

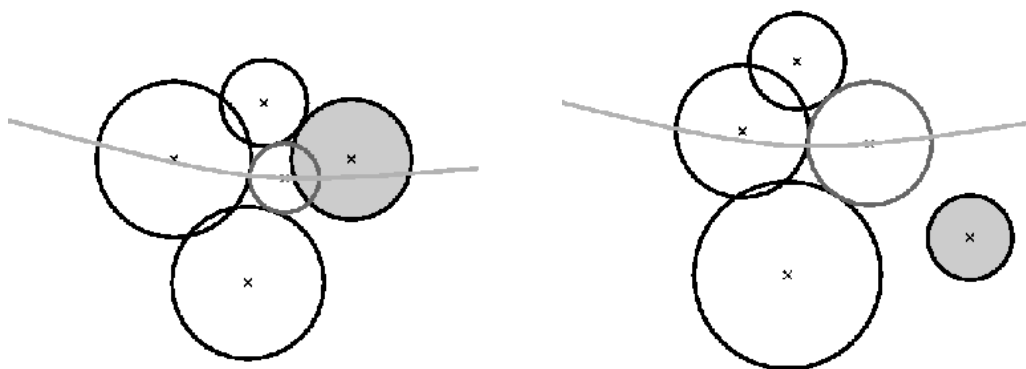

Figure 43.2: The *Vertex_conflict_2* predicate. The left-most, bottom-most and top-most circles define the tritangent circle in the middle. We want to determine the sign of the distance of the left-most circle from the one in the middle. The almost horizontal curve is the bisector of the top-most and bottom-most circles. Left: the predicate returns *CGAL::NEGATIVE*. Right: the predicate returns *CGAL::POSITIVE*.

What we essentially want to compute when we construct incrementally a Voronoi diagram, is whether the object to be inserted destroys an edge of the Voronoi diagram or not. In the case of points this is really easy and it amounts to the well known *incircle* test. In the case of circles the situation is more complicated. We can have six possible outcomes as to what portion of an edge of the Apollonius diagram the new circle destroys (see Fig. 43.3). The first two can be answered directly by the *Vertex_conflict_2* predicate evaluated for the two endpoints of the Apollonius diagram edge. This is due to the fact that the value of the *Vertex_conflict_2* predicate is different for the two endpoints. If the two values are the same then we need an additional test which determines if the interior of the Apollonius diagram edge is destroyed by the new circle. This is what the *Finite_edge_interior_conflict_2* and *Infinite_edge_interior_conflict_2* predicates do. In essence, it is the same predicate (same idea) applied to two different types of edges in the Apollonius diagram: a finite or an infinite edge. An edge is infinite if its dual edge in the Apollonius graph connects the site at infinity with the vertex corresponding to a (finite) circle; otherwise it is a finite edge.

The last predicate that we want to discuss is called *Is_degenerate_edge_2*. It tells us whether an edge in the Apollonius diagram is degenerate, that is if its two endpoints coincide. In the Apollonius graph such an edge corresponds to one of the additional edges that we use to triangulate the non-triangular faces.

The aforementioned predicates are part of the *ApolloniusGraphTraits_2* concept of CGAL. CGAL also provides a model for this concept, the *Apollonius_graph_traits_2<K,Method_tag>* class. The first template parameter of this class must be a model of the *Kernel* concept. The second template parameter is a tag that indicates what operations are allowed in the computations that take place within the traits class. The two possible values of the *Method_tag* parameter are *CGAL::Ring_tag* and *CGAL::Sqrt_field_tag*. When *CGAL::Ring_tag* is used, only ring operations are used during the evaluation of the predicates, whereas if *CGAL::Sqrt_field_tag* is chosen, all four field operations, as well as square roots, are used during the predicate evaluation.

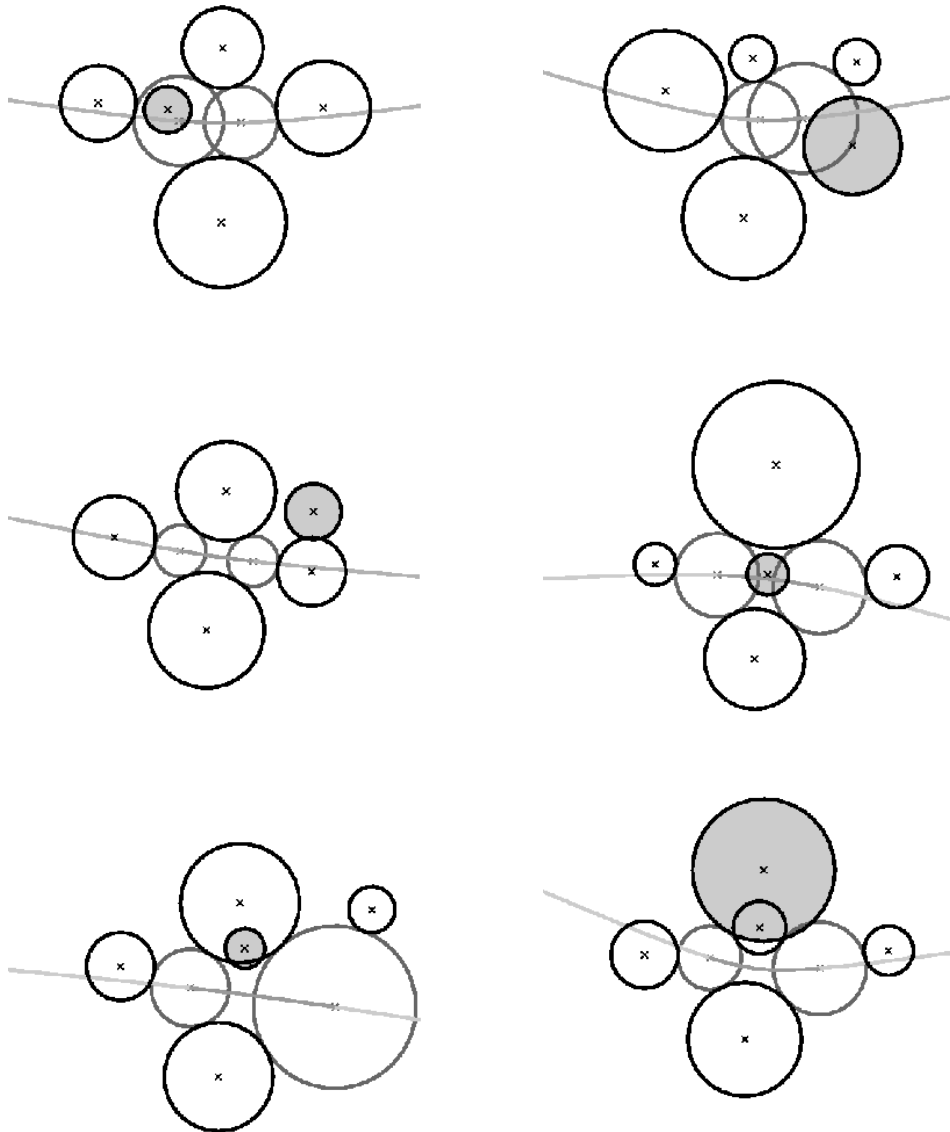

Figure 43.3: The 6 possible outcomes of the *Finite_edge_interior_conflict_2* predicate. Top left: only a neighborhood around the left-most endpoint of the edge will be destroyed. Top right: only a neighborhood around the right-most endpoint of the edge will be destroyed. Middle left: no portion of the edge is destroyed. Middle right: the entire edge will be destroyed. Bottom left: a neighborhood in the interior of the edge will be destroyed; the regions near the endpoints remain unaffected. Bottom right: The neighborhood around the two endpoints will be destroyed, but an interval in the interior of the edge will remain in the new diagram.

The *Apollonius_graph_traits_2* $\langle K, \text{Method_tag} \rangle$ class provides exact predicates if the number type in the kernel K is an exact number type. This is to be associated with the type of operations allowed for the predicate evaluation. For example *CGAL::MP_Float* as number type, with *CGAL::Ring_tag* as tag will give exact predicates, whereas *CGAL::MP_Float* with *CGAL::Sqrt_field_tag* will give inexact predicates.

Since using an exact number type may be too slow, the *Apollonius_graph_traits_2* $\langle K, \text{Method_tag} \rangle$ class is

designed to support the dynamic filtering of CGAL through the `CGAL::Filtered_exact<CT,ET>` mechanism. In particular if `CT` is an inexact number type that supports the operations denoted by the tag `Method_tag` and `ET` is an exact number type for these operations, then kernel with number type `CGAL::Filtered_exact<CT,ET>` will yield exact predicates for the Apollonius graph traits. To give a concrete example, `CGAL::Filtered_exact<double,CGAL::MP_Float>` with `CGAL::Ring_tag` will produce exact predicates.

Another possibility for fast and exact predicate evaluation is to use the `Apollonius_graph_filtered_traits_2<CK,CM,EK,EM,FK,FM>` class. This class is the analog of a filtered kernel. It takes a constructions kernel `CK`, a filtering kernel `FK` and an exact kernel `EK`, as well as the corresponding tags (`CM`, `FM` and `EM`, respectively). It evaluates the predicates by first using the filtering kernel, and if this fails the evaluation is performed using the exact kernel. The constructions are done using the kernel `CK`, which means that they are not necessarily exact. All template parameters except `CK` have default values, which are explained in the reference manual.

43.4 The Apollonius Graph Hierarchy

The `Apollonius_graph_hierarchy_2<ApolloniusGraphTraits_2,ApolloniusGraphDataStructure_2>` class is nothing but the equivalent of the `Triangulation_hierarchy_2` class, applied to the Apollonius graph. It consists of a series of Apollonius graphs constructed in a manner analogous to the Delaunay hierarchy by Devillers [Dev98]. The class `Apollonius_graph_hierarchy_2<ApolloniusGraphTraits_2,ApolloniusGraphDataStructure_2>` has exactly the same interface and functionality as the `Apollonius_graph_2<ApolloniusGraphTraits_2,ApolloniusGraphDataStructure_2>` class. Using the Apollonius graph hierarchy involves an additional cost in space and time for maintaining the hierarchy. Our experiments have shown that it usually pays off to use the hierarchy for inputs consisting of more than 1,000 circles. This threshold holds for both the construction of the Apollonius diagram itself, as well as for nearest neighbor queries.

43.5 Examples

43.5.1 First Example

```
#include <CGAL/basic.h>

// standard includes
#include <iostream>
#include <fstream>
#include <cassert>

// the number type
#include <CGAL/MP_Float.h>

// example that uses an exact number type

typedef CGAL::MP_Float NT;

// choose the kernel
#include <CGAL/Simple_cartesian.h>

typedef CGAL::Simple_cartesian<NT> Kernel;
```

```

// typedefs for the traits and the algorithm

#include <CGAL/Apollonius_graph_2.h>
#include <CGAL/Apollonius_graph_traits_2.h>

typedef CGAL::Apollonius_graph_traits_2<Kernel> Traits;
typedef CGAL::Apollonius_graph_2<Traits> Apollonius_graph;

int main()
{
    std::ifstream ifs("data/sites.cin");
    assert( ifs );

    Apollonius_graph ag;
    Apollonius_graph::Site_2 site;

    // read the sites and insert them in the Apollonius graph
    while ( ifs >> site ) {
        ag.insert(site);
    }

    // validate the Apollonius graph
    assert( ag.is_valid(true, 1) );
    std::cout << std::endl;

    return 0;
}

```

File: examples/Apollonius_graph_2/ag2_exact_traits.cpp

43.5.2 Second Example

```

#include <CGAL/basic.h>

// standard includes
#include <iostream>
#include <fstream>
#include <cassert>

#if defined CGAL_USE_LEDA
#   include <CGAL/leda_real.h>
#elif defined CGAL_USE_CORE
#   include <CGAL/CORE_Expr.h>
#endif

#if defined CGAL_USE_LEDA
// If LEDA is present use leda_real as the exact number type
typedef leda_real NT;

```

```

#elif defined CGAL_USE_CORE
// Otherwise if CORE is present use CORE's Expr as the exact number type
typedef CORE::Expr NT;

#else

// Otherwise just use double. This may cause numerical errors but it
// is still worth doing it to show how to define correctly the traits
// class
typedef double NT;

#endif

#include <CGAL/Simple_cartesian.h>

typedef CGAL::Simple_cartesian<NT> Kernel;

// typedefs for the traits and the algorithm

#include <CGAL/Apollonius_graph_2.h>
#include <CGAL/Apollonius_graph_traits_2.h>

// the traits class is now going to assume that the operations
// +,-,*,/ and sqrt are supported exactly
typedef
CGAL::Apollonius_graph_traits_2<Kernel,CGAL::Field_with_sqrt_tag> Traits;

typedef CGAL::Apollonius_graph_2<Traits> Apollonius_graph;

int main()
{
    std::ifstream ifs("data/sites.cin");
    assert( ifs );

    Apollonius_graph ag;
    Apollonius_graph::Site_2 site;

    // read the sites and insert them in the Apollonius graph
    while ( ifs >> site ) {
        ag.insert(site);
    }

    // validate the Apollonius graph
    assert( ag.is_valid(true, 1) );
    std::cout << std::endl;

    return 0;
}

```

File: examples/Apollonius_graph_2/ag2_exact_traits_sqrt.cpp

43.5.3 Third Example

```
#include <CGAL/basic.h>

// standard includes
#include <iostream>
#include <fstream>
#include <cassert>

#include <CGAL/basic.h>

// example that uses the filtered traits

// choose the representation
#include <CGAL/Simple_cartesian.h>

typedef CGAL::Simple_cartesian<double> Rep;

#include <CGAL/Apollonius_graph_2.h>
#include <CGAL/Triangulation_data_structure_2.h>
#include <CGAL/Apollonius_graph_vertex_base_2.h>
#include <CGAL/Triangulation_face_base_2.h>
#include <CGAL/Apollonius_graph_filtered_traits_2.h>

// typedef for the traits; the filtered traits class is used
typedef CGAL::Apollonius_graph_filtered_traits_2<Rep> Traits;

// typedefs for the algorithm

// With the second template argument in the vertex base class being
// false, we indicate that there is no need to store the hidden sites.
// One case where this is indeed not needed is when we only do
// insertions, like in the main program below.
typedef CGAL::Apollonius_graph_vertex_base_2<Traits,false> Vb;
typedef CGAL::Triangulation_face_base_2<Traits> Fb;
typedef CGAL::Triangulation_data_structure_2<Vb,Fb> Agds;
typedef CGAL::Apollonius_graph_2<Traits,Agds> Apollonius_graph;

int main()
{
    std::ifstream ifs("data/sites.cin");
    assert( ifs );

    Apollonius_graph ag;
    Apollonius_graph::Site_2 site;

    // read the sites and insert them in the Apollonius graph
    while ( ifs >> site ) {
        ag.insert(site);
    }
}
```

```

// validate the Apollonius graph
assert( ag.is_valid(true, 1) );
std::cout << std::endl;

// now remove all sites
std::cout << "Removing all sites... " << std::flush;
while ( ag.number_of_vertices() > 0 ) {
    ag.remove( ag.finite_vertex() );
}
std::cout << "done!" << std::endl << std::endl;

return 0;
}

```

File: examples/Apollonius_graph_2/ag2_filtered_traits_no_hidden.cpp

43.5.4 Fourth Example

```

#include <CGAL/basic.h>

// standard includes
#include <iostream>
#include <fstream>
#include <cassert>

// example that uses the filtered traits

#include <CGAL/MP_Float.h>
#include <CGAL/Simple_cartesian.h>

// constructions kernel (inexact)
typedef CGAL::Simple_cartesian<double> CK;

// exact kernel
typedef CGAL::Simple_cartesian<CGAL::MP_Float> EK;

// typedefs for the traits and the algorithm

#include <CGAL/Apollonius_graph_hierarchy_2.h>
#include <CGAL/Apollonius_graph_filtered_traits_2.h>

// Type definition for the traits class.
// In this example we explicitly define the exact kernel. We also
// explicitly define what operations to use for the evaluation of the
// predicates and constructions, when the filtering and the exact
// kernels are used respectively.
// Note that the operations allowed for the filtering and the
// constructions (field operations plus square roots) are different
// from the operations allowed when the exact kernel is used (ring

```

```

// operations).
typedef CGAL::Field_with_sqrt_tag CM;
typedef CGAL::Integral_domain_without_division_tag EM;
typedef CGAL::Apollonius_graph_filtered_traits_2<CK,CM,EK,EM> Traits;

// Now we use the Apollonius graph hierarchy.
// The hierarchy is faster for inputs consisting of about more than
// 1,000 sites
typedef CGAL::Apollonius_graph_hierarchy_2<Traits> Apollonius_graph;

int main()
{
    std::ifstream ifs("data/hierarchy.cin");
    assert( ifs );

    Apollonius_graph ag;
    Apollonius_graph::Site_2 site;

    // read the sites and insert them in the Apollonius graph
    while ( ifs >> site ) {
        ag.insert(site);
    }

    // validate the Apollonius graph
    assert( ag.is_valid(true, 1) );

    return 0;
}

```

File: examples/Apollonius_graph_2/ag2_hierarchy.cpp

2D Apollonius Graphs (Delaunay Graphs of Disks)

Reference Manual

Menelaos Karavelas and Mariette Yvinec

An Apollonius graph is the dual of the Apollonius diagram, also known as the *additively weighted Voronoi diagram*. It is essentially the Voronoi diagram of a set of disks, where the distance of a point of the plane from a disk is defined as the Euclidean distance of the point and the center of the circle, minus the radius of the disk.

CGAL provides the class `CGAL::Apollonius_graph_2<Gt,Agds>` for computing the 2D Apollonius graph. The two template parameters must be models of the `ApolloniusGraphTraits_2` and `ApolloniusGraphDataStructure_2` concepts. The first concept is related to the geometric objects and predicates associated with Apollonius graphs, whereas the second concept refers to the data structure used to represent the Apollonius graph. The classes `Apollonius_graph_traits_2<K,Method_tag>` and `Triangulation_data_structure_2<Vb,Fb>` are models of the aforementioned concepts.

CGAL::Apollonius_graph_2<Gt,Agds>

Definition

The class *Apollonius_graph_2<Gt,Agds>* represents the Apollonius graph. It supports insertions and deletions of sites. It is templated by two template arguments *Gt*, which must be a model of *ApolloniusGraphTraits_2*, and *Agds*, which must be a model of *ApolloniusGraphDataStructure_2*. The second template argument defaults to *CGAL::Triangulation_data_structure_2<CGAL::Apollonius_graph_vertex_base_2<Gt,true>, CGAL::Triangulation_face_base_2<Gt>>*.

```
#include <CGAL/Apollonius_graph_2.h>
```

Is Model for the Concepts

DelaunayGraph_2

Types

<i>typedef Agds</i>	<i>Data_structure;</i>	A type for the underlying data structure.
<i>typedef Data_structure</i>	<i>Triangulation_data_structure;</i>	Same as the <i>Data_structure</i> type. This type has been introduced in order for the <i>Apollonius_graph_2<Gt,Agds></i> class to be a model of the <i>DelaunayGraph_2</i> concept.
<i>typedef Gt</i>	<i>Geom_traits;</i>	A type for the geometric traits.
<i>typedef Gt::Point_2</i>	<i>Point_2;</i>	A type for the point defined in the geometric traits.
<i>typedef Gt::Site_2</i>	<i>Site_2;</i>	A type for the Apollonius site, defined in the geometric traits.

The vertices and faces of the Apollonius graph are accessed through *handles*, *iterators* and *circulators*. The iterators and circulators are all bidirectional and non-mutable. The circulators and iterators are assignable to the corresponding handle types, and they are also convertible to the corresponding handles. The edges of the Apollonius graph can also be visited through iterators and circulators, the edge circulators and iterators are also bidirectional and non-mutable. In the following, we call *infinite* any face or edge incident to the infinite vertex and the infinite vertex itself. Any other feature (face, edge or vertex) of the Apollonius graph is said to be *finite*. Some iterators (the *All* iterators) allow to visit finite or infinite features while the others (the *Finite* iterators) visit only finite features. Circulators visit both infinite and finite features.

<i>typedef Data_structure::Edge</i>	<i>Edge;</i>	the edge type. The <i>Edge(f,i)</i> is the edge common to faces <i>f</i> and <i>f.neighbor(i)</i> . It is also the edge joining the vertices <i>vertex(cw(i))</i> and <i>vertex(ccw(i))</i> of <i>f</i> . <i>Precondition:</i> <i>i</i> must be 0, 1 or 2.
<i>typedef Data_structure::Vertex</i>	<i>Vertex;</i>	A type for a vertex.
<i>typedef Data_structure::Face</i>	<i>Face;</i>	A type for a face.
<i>typedef Data_structure::Vertex_handle</i>	<i>Vertex_handle;</i>	A type for a handle to a vertex.
<i>typedef Data_structure::Face_handle</i>	<i>Face_handle;</i>	A type for a handle to a face.
<i>typedef Data_structure::Vertex_circulator</i>	<i>Vertex_circulator;</i>	A type for a circulator over vertices incident to a given vertex.

<i>typedef Data_structure::Face_circulator</i>	<i>Face_circulator;</i>	A type for a circulator over faces incident to a given vertex.
<i>typedef Data_structure::Edge_circulator</i>	<i>Edge_circulator;</i>	A type for a circulator over edges incident to a given vertex.
<i>typedef Data_structure::Vertex_iterator</i>	<i>All_vertices_iterator;</i>	A type for an iterator over all vertices.
<i>typedef Data_structure::Face_iterator</i>	<i>All_faces_iterator;</i>	A type for an iterator over all faces.
<i>typedef Data_structure::Edge_iterator</i>	<i>All_edges_iterator;</i>	A type for an iterator over all edges.
<i>typedef Data_structure::size_type</i>	<i>size_type;</i>	An unsigned integral type.
<i>Apollonius_graph_2<Gt,Agds>:: Finite_vertices_iterator</i>		A type for an iterator over finite vertices.
<i>Apollonius_graph_2<Gt,Agds>:: Finite_faces_iterator</i>		A type for an iterator over finite faces.
<i>Apollonius_graph_2<Gt,Agds>:: Finite_edges_iterator</i>		A type for an iterator over finite edges.

In addition to iterators and circulators for vertices and faces, iterators for sites are provided. In particular there are iterators for the entire set of sites, the hidden sites and the visible sites of the Apollonius graph.

<i>Apollonius_graph_2<Gt,Agds>:: Sites_iterator</i>	A type for an iterator over all sites.
<i>Apollonius_graph_2<Gt,Agds>:: Visible_sites_iterator</i>	A type for an iterator over all visible sites.
<i>Apollonius_graph_2<Gt,Agds>:: Hidden_sites_iterator</i>	A type for an iterator over all hidden sites.

Creation

Apollonius_graph_2<Gt,Agds> ag(Gt gt=Gt()); Creates an Apollonius graph using *gt* as geometric traits.

template< class Input_iterator >

Apollonius_graph_2<Gt,Agds> ag(Input_iterator first, Input_iterator beyond, Gt gt=Gt());

Creates an Apollonius graph using *gt* as geometric traits and inserts all sites in the range [*first*, *beyond*).

Precondition: *Input_iterator* must be a model of *InputIterator*. The value type of *Input_iterator* must be *Site_2*.

Apollonius_graph_2<Gt,Agds> ag(other); Copy constructor. All faces and vertices are duplicated. After the construction, *ag* and *other* refer to two different Apollonius graphs : if *other* is modified, *ag* is not.

Apollonius_graph_2<Gt,Agds> ag = other Assignment. If *ag* and *other* are the same object nothing is done. Otherwise, all the vertices and faces are duplicated. After the assignment, *ag* and *other* refer to different Apollonius graphs : if *other* is modified, *ag* is not.

Access Functions

<i>Geom_traits</i>	<i>ag.geom_traits()</i>	Returns a reference to the Apollonius graph traits object.
<i>Data_structure</i>	<i>ag.data_structure()</i>	Returns a reference to the underlying data structure.
<i>Data_structure</i>	<i>ag.tds()</i>	Same as <i>data_structure()</i> . This method has been added in compliance with the <i>DelaunayGraph_2</i> concept.
<i>int</i>	<i>ag.dimension()</i>	Returns the dimension of the Apollonius graph.
<i>size_type</i>	<i>ag.number_of_vertices()</i>	Returns the number of finite vertices.
<i>size_type</i>	<i>ag.number_of_visible_sites()</i>	Returns the number of visible sites.

<i>size_type</i>	<i>ag.number_of_hidden_sites()</i>	Returns the number of hidden sites.
<i>size_type</i>	<i>ag.number_of_faces()</i>	Returns the number of faces (both finite and infinite) of the Apollonius graph.
<i>Face_handle</i>	<i>ag.infinite_face()</i>	Returns a face incident to the <i>infinite_vertex</i> .
<i>Vertex_handle</i>	<i>ag.infinite_vertex()</i>	Returns the <i>infinite_vertex</i> .
<i>Vertex_handle</i>	<i>ag.finite_vertex()</i>	Returns a vertex distinct from the <i>infinite_vertex</i> . <i>Precondition:</i> The number of (visible) vertices in the Apollonius graph must be at least one.

Traversal of the Apollonius graph

An Apollonius graph can be seen as a container of faces and vertices. Therefore the Apollonius graph provides several iterators and circulators that allow to traverse it (completely or partially).

Face, Edge and Vertex Iterators

The following iterators allow respectively to visit finite faces, finite edges and finite vertices of the Apollonius graph. These iterators are non-mutable, bidirectional and their value types are respectively *Face*, *Edge* and *Vertex*. They are all invalidated by any change in the Apollonius graph.

<i>Finite_vertices_iterator</i>	<i>ag.finite_vertices_begin()</i>	Starts at an arbitrary finite vertex.
<i>Finite_vertices_iterator</i>	<i>ag.finite_vertices_end()</i>	Past-the-end iterator.
<i>Finite_edges_iterator</i>	<i>ag.finite_edges_begin()</i>	Starts at an arbitrary finite edge.
<i>Finite_edges_iterator</i>	<i>ag.finite_edges_end()</i>	Past-the-end iterator.
<i>Finite_faces_iterator</i>	<i>ag.finite_faces_begin()</i>	Starts at an arbitrary finite face.
<i>Finite_faces_iterator</i>	<i>ag.finite_faces_end()</i>	Past-the-end iterator.

The following iterators allow respectively to visit all (both finite and infinite) faces, edges and vertices of the Apollonius graph. These iterators are non-mutable, bidirectional and their value types are respectively *Face*, *Edge* and *Vertex*. They are all invalidated by any change in the Apollonius graph.

<i>All_vertices_iterator</i>	<i>ag.all_vertices_begin()</i>	Starts at an arbitrary vertex.
<i>All_vertices_iterator</i>	<i>ag.all_vertices_end()</i>	Past-the-end iterator.
<i>All_edges_iterator</i>	<i>ag.all_edges_begin()</i>	Starts at an arbitrary edge.
<i>All_edges_iterator</i>	<i>ag.all_edges_end()</i>	Past-the-end iterator.
<i>All_faces_iterator</i>	<i>ag.all_faces_begin()</i>	Starts at an arbitrary face.
<i>All_faces_iterator</i>	<i>ag.all_faces_end()</i>	Past-the-end iterator.

Site iterators

The following iterators allow respectively to visit all sites, the visible sites and the hidden sites. These iterators are non-mutable, bidirectional and their value type is *Site_2*. They are all invalidated by any change in the Apollonius graph.

<i>Sites_iterator</i>	<i>ag.sites_begin()</i>	Starts at an arbitrary site.
-----------------------	-------------------------	------------------------------

<i>Sites_iterator</i>	<i>ag.sites_end()</i>	Past-the-end iterator.
<i>Visible_sites_iterator</i>	<i>ag.visible_sites_begin()</i>	Starts at an arbitrary visible site.
<i>Visible_sites_iterator</i>	<i>ag.visible_sites_end()</i>	Past-the-end iterator.
<i>Hidden_sites_iterator</i>	<i>ag.hidden_sites_begin()</i>	Starts at an arbitrary hidden site.
<i>Hidden_sites_iterator</i>	<i>ag.hidden_sites_end()</i>	Past-the-end iterator.

Face, Edge and Vertex Circulators

The Apollonius graph also provides circulators that allow to visit respectively all faces or edges incident to a given vertex or all vertices adjacent to a given vertex. These circulators are non-mutable and bidirectional. The operator *operator++* moves the circulator counterclockwise around the vertex while the *operator--* moves clockwise. A face circulator is invalidated by any modification of the face pointed to. An edge circulator is invalidated by any modification in one of the two faces incident to the edge pointed to. A vertex circulator is invalidated by any modification in any of the faces adjacent to the vertex pointed to.

<i>Face_circulator</i>	<i>ag.incident_faces(Vertex_handle v)</i>	Starts at an arbitrary face incident to <i>v</i> .
<i>Face_circulator</i>	<i>ag.incident_faces(Vertex_handle v, Face_handle f)</i>	Starts at face <i>f</i> . Precondition: Face <i>f</i> is incident to vertex <i>v</i> .
<i>Edge_circulator</i>	<i>ag.incident_edges(Vertex_handle v)</i>	Starts at an arbitrary edge incident to <i>v</i> .
<i>Edge_circulator</i>	<i>ag.incident_edges(Vertex_handle v, Face_handle f)</i>	Starts at the first edge of <i>f</i> incident to <i>v</i> , in counterclockwise order around <i>v</i> . Precondition: Face <i>f</i> is incident to vertex <i>v</i> .
<i>Vertex_circulator</i>	<i>ag.incident_vertices(Vertex_handle v)</i>	Starts at an arbitrary vertex incident to <i>v</i> .
<i>Vertex_circulator</i>	<i>ag.incident_vertices(Vertex_handle v, Face_handle f)</i>	Starts at the first vertex of <i>f</i> adjacent to <i>v</i> in counterclockwise order around <i>v</i> . Precondition: Face <i>f</i> is incident to vertex <i>v</i> .

Traversal of the Convex Hull

Applied on the *infinite_vertex* the above functions allow to visit the vertices on the convex hull and the infinite edges and faces. Note that a counterclockwise traversal of the vertices adjacent to the *infinite_vertex* is a clockwise traversal of the convex hull.

<i>Vertex_circulator</i>	<i>ag.incident_vertices(ag.infinite_vertex())</i>
<i>Vertex_circulator</i>	<i>ag.incident_vertices(ag.infinite_vertex(), Face_handle f)</i>
<i>Face_circulator</i>	<i>ag.incident_faces(ag.infinite_vertex())</i>

<i>Face_circulator</i>	<i>ag.incident_faces(ag.infinite_vertex(), Face_handle f)</i>
<i>Edge_circulator</i>	<i>ag.incident_edges(ag.infinite_vertex())</i>
<i>Edge_circulator</i>	<i>ag.incident_edges(ag.infinite_vertex(), Face_handle f)</i>

Predicates

The class *Apollonius_graph_2<Gt,Agds>* provides methods to test the finite or infinite character of any feature.

<i>bool</i>	<i>ag.is_infinite(Vertex_handle v)</i>	<i>true</i> , iff <i>v</i> is the <i>infinite_vertex</i> .
<i>bool</i>	<i>ag.is_infinite(Face_handle f)</i>	<i>true</i> , iff face <i>f</i> is infinite.
<i>bool</i>	<i>ag.is_infinite(Face_handle f, int i)</i>	<i>true</i> , iff edge (<i>f</i> , <i>i</i>) is infinite.
<i>bool</i>	<i>ag.is_infinite(Edge e)</i>	<i>true</i> , iff edge <i>e</i> is infinite.
<i>bool</i>	<i>ag.is_infinite(Edge_circulator ec)</i>	<i>true</i> , iff edge <i>*ec</i> is infinite.

Insertion

```
template< class Input_iterator >
unsigned int    ag.insert( Input_iterator first, Input_iterator beyond)
```

Inserts the sites in the range [*first*,*beyond*). The number of sites in the range [*first*, *beyond*) is returned.

Precondition: *Input_iterator* must be a model of *InputIterator* and its value type must be *Site_2*.

<i>Vertex_handle</i>	<i>ag.insert(Site_2 s)</i>	Inserts the site <i>s</i> in the Apollonius graph. If <i>s</i> is visible then the vertex handle of <i>s</i> is returned, otherwise <i>Vertex_handle(NULL)</i> is returned.
----------------------	-----------------------------	---

<i>Vertex_handle</i>	<i>ag.insert(Site_2 s, Vertex_handle vnear)</i>
----------------------	--

Inserts *s* in the Apollonius graph using the site associated with *vnear* as an estimate for the nearest neighbor of the center of *s*. If *s* is visible then the vertex handle of *s* is returned, otherwise *Vertex_handle(NULL)* is returned.

Removal

<i>void</i>	<i>ag.remove(Vertex_handle v)</i>	Removes the site associated to the vertex handle <i>v</i> from the Apollonius graph. <i>Precondition:</i> <i>v</i> must correspond to a valid finite vertex of the Apollonius graph.
-------------	------------------------------------	---

Nearest neighbor location

<i>Vertex_handle</i>	<i>ag.nearest_neighbor(Point_2 p)</i>	Finds the nearest neighbor of the point <i>p</i> . In other words it finds the site whose Apollonius cell contains <i>p</i> . Ties are broken arbitrarily and one of the nearest neighbors of <i>p</i> is returned. If there are no visible sites in the Apollonius diagram <i>Vertex_handle(NULL)</i> is returned.
----------------------	--	---

Vertex_handle *ag.nearest_neighbor(Point_2 p, Vertex_handle vnear)*

Finds the nearest neighbor of the point *p* using the site associated with *vnear* as an estimate for the nearest neighbor of *p*. Ties are broken arbitrarily and one of the nearest neighbors of *p* is returned. If there are no visible sites in the Apollonius diagram *Vertex_handle(NULL)* is returned.

Access to the dual

The *Apollonius_graph_2* class provides access to the duals of the faces of the graph. The dual of a face of the Apollonius graph is a site. If the originating face is infinite, its dual is a site with center at infinity (or equivalently with infinite weight), which means that it can be represented geometrically as a line. If the originating face is finite, its dual is a site with finite center and weight. In the following three methods the returned object is assignable to either *Site_2* or *Gt::Line_2*, depending on whether the corresponding face of the Apollonius graph is finite or infinite, respectively.

<i>Gt::Object_2</i> <i>ag.dual(Face_handle f)</i>	Returns the dual corresponding to the face handle <i>f</i> . The returned object can be assignable to one of the following: <i>Site_2</i> , <i>Gt::Line_2</i> .
<i>Gt::Object_2</i> <i>ag.dual(All_faces_iterator it)</i>	Returns the dual of the face to which <i>it</i> points to. The returned object can be assignable to one of the following: <i>Site_2</i> , <i>Gt::Line_2</i> .
<i>Gt::Object_2</i> <i>ag.dual(Finite_faces_iterator it)</i>	Returns the dual of the face to which <i>it</i> points to. The returned object can be assignable to one of the following: <i>Site_2</i> , <i>Gt::Line_2</i> .

I/O

<pre>template< class Stream > Stream& ag.draw_primal(Stream& str)</pre>	<p>Draws the Apollonius graph to the stream <i>str</i>. <i>Precondition:</i> The following operators must be defined: <i>Stream& operator<<(Stream&, Gt::Segment_2),</i> <i>Stream& operator<<(Stream&, Gt::Ray_2).</i></p>
<pre>template < class Stream > Stream& ag.draw_dual(Stream& str)</pre>	<p>Draws the dual of the Apollonius graph, i.e., the Apollonius diagram, to the stream <i>str</i>. <i>Precondition:</i> The following operators must be defined: <i>Stream& operator<<(Stream&, Gt::Segment_2),</i> <i>Stream& operator<<(Stream&, Gt::Ray_2),</i> <i>Stream& operator<<(Stream&, Gt::Line_2).</i></p>
<pre>template< class Stream > Stream& ag.draw_primal_edge(Edge e, Stream& str)</pre>	<p>Draws the edge <i>e</i> of the Apollonius graph to the stream <i>str</i>. <i>Precondition:</i> The following operators must be defined: <i>Stream& operator<<(Stream&, Gt::Segment_2),</i> <i>Stream& operator<<(Stream&, Gt::Ray_2).</i></p>
<pre>template< class Stream ></pre>	

<i>Stream&</i>	<i>ag.draw_dual_edge(Edge e, Stream& str)</i>	Draws the dual of the edge <i>e</i> to the stream <i>str</i> . The dual of <i>e</i> is an edge of the Apollonius diagram. <i>Precondition:</i> The following operators must be defined: <i>Stream& operator<<(Stream&, Gt::Segment_2),</i> <i>Stream& operator<<(Stream&, Gt::Ray_2),</i> <i>Stream& operator<<(Stream&, Gt::Line_2).</i>
<i>void</i>	<i>ag.file_output(std::ostream& os)</i>	Writes the current state of the Apollonius graph to an output stream. In particular, all visible and hidden sites are written as well as the underlying combinatorial data structure.
<i>void</i>	<i>ag.file_input(std::istream& is)</i>	Reads the state of the Apollonius graph from an input stream.
<i>std::ostream&</i>	<i>std::ostream& os << ag</i>	Writes the current state of the Apollonius graph to an output stream.
<i>std::istream&</i>	<i>std::istream& is >> ag</i>	Reads the state of the Apollonius graph from an input stream.

Validity check

<i>bool</i>	<i>ag.is_valid(bool verbose = false, int level = 1)</i>	Checks the validity of the Apollonius graph. If <i>verbose</i> is <i>true</i> a short message is sent to <i>std::cerr</i> . If <i>level</i> is 0, only the data structure is validated. If <i>level</i> is 1, then both the data structure and the Apollonius graph are validated. Negative values of <i>level</i> always return true, and values greater than 1 are equivalent to <i>level</i> being 1.
-------------	--	--

Miscellaneous

<i>void</i>	<i>ag.clear()</i>	Clears all contents of the Apollonius graph.
<i>void</i>	<i>ag.swap(other)</i>	The Apollonius graphs <i>other</i> and <i>ag</i> are swapped. <i>ag.swap(other)</i> should be preferred to <i>ag= other</i> or to <i>ag(other)</i> if <i>other</i> is deleted afterwards.

ApolloniusSite_2

Definition

The concept *ApolloniusSite_2* provides the requirements for an Apollonius site class.

Types

<i>ApolloniusSite_2:: Point_2</i>	The point type.
<i>ApolloniusSite_2:: FT</i>	The field number type.
<i>ApolloniusSite_2:: RT</i>	The ring number type.
<i>ApolloniusSite_2:: Weight</i>	The weight type.
<i>Precondition:</i> It must be the same as <i>FT</i> .	

Creation

ApolloniusSite_2 *s*(*Point_2* *p*=*Point_2*(), *Weight* *w*= *Weight*(0));
ApolloniusSite_2 *s*(*other*); Copy constructor.

Access Functions

<i>Point_2</i>	<i>s.point()</i>	Returns the center of the Apollonius site.
<i>Weight</i>	<i>s.weight()</i>	Returns the weight of the Apollonius site.

CGAL::Apollonius_site_2<K>

Definition

The class *Apollonius_site_2*<*K*> is a model for the concept *ApolloniusSite_2*. It is parametrized by a template parameter *K* which must be a model of the *Kernel* concept.

```
#include <CGAL/Apollonius_site_2.h>
```

Is Model for the Concepts

ApolloniusSite_2

Types

The class *Apollonius_site_2*<*K*> does not introduce any types in addition to the concept *ApolloniusSite_2*.

Creation

```
Apollonius_site_2<K> s( Point_2 p=Point_2(), Weight w= Weight(0));  
Apollonius_site_2<K> s( other);           Copy constructor.
```

I/O

The I/O operators are defined for *iostream*.

```
std::ostream&      std::ostream& os << s      Inserts the Apollonius site s into the stream os.  
                  Precondition: The insert operator must be defined for Point_2 and  
                  Weight.
```

```
std::istream&      std::istream& is >> s      Reads an Apollonius site from the stream is and assigns it to s.  
                  Precondition: The extract operator must be defined for Point_2 and  
                  Weight.
```

The information output in the *iostream* is: the point of the Apollonius site and its weight.

```
#include <CGAL/IO/Qt_widget_Apollonius_site_2.h>
```

```
Qt_widget&         Qt_widget& w << s          Inserts the Apollonius site s into the Qt_widget stream w.  
                  Precondition: The insert operator must be defined for K::Circle_2.
```

ApolloniusGraphDataStructure_2

Definition

The concept *ApolloniusGraphDataStructure_2* refines the concept *TriangulationDataStructure_2*. In addition it provides two methods for the insertion and removal of a degree 2 vertex in the data structure. The insertion method adds a new vertex to the specified edge, thus creating two new edges. Moreover, it creates two new faces that have the two newly created edges in common (see figure below). The removal method performs the reverse operation.

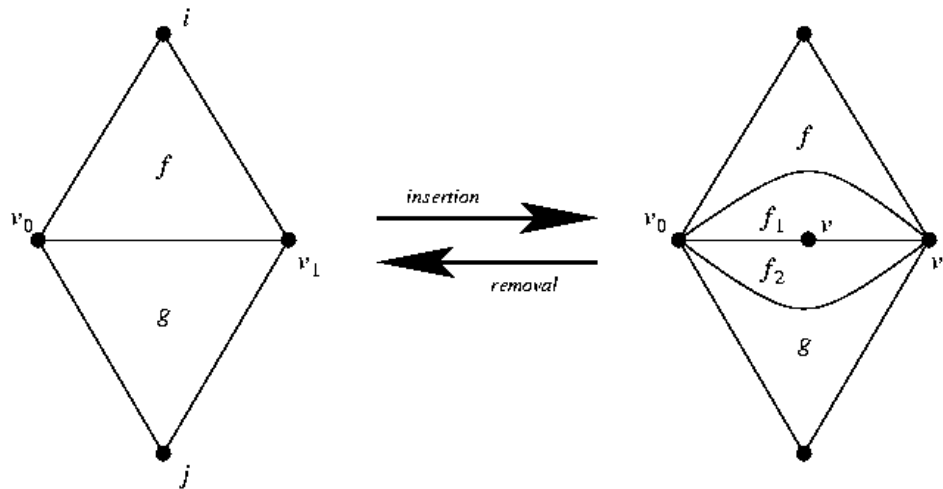

Figure 43.4: Insertion and removal of degree 2 vertices. Left to right: The edge (f,i) is replaced by two edges by means of inserting a vertex v on the edge. The faces f_1 and f_2 are created. Right to left: the faces f_1 and f_2 are destroyed. The vertex v is deleted and its two adjacent edges are merged.

We only describe the additional requirements with respect to the *TriangulationDataStructure_2* concept.

Refines

TriangulationDataStructure_2

Insertion

Vertex_handle `agds.insert_degree_2(Face_handle f, int i)`

Inserts a degree two vertex and two faces adjacent to it that have two common edges. The edge defined by the face handle f and the integer i is duplicated. It returns a handle to the vertex created.

Removal

void *agds.remove_degree_2(Vertex_handle v)* Removes a degree 2 vertex and the two faces adjacent to it. The two edges of the star of v that are not incident to it are collapsed.
Precondition: The degree of v must be equal to 2.

ApolloniusGraphVertexBase_2

Definition

The concept *ApolloniusGraphVertexBase_2* describes the requirements for the vertex base class of the *ApolloniusGraphDataStructure_2* concept. A vertex stores an Apollonius site and provides access to one of its incident faces through a *Face_handle*. In addition, it maintains a container of sites. The container stores the hidden sites related to the vertex.

Types

<i>ApolloniusGraphVertexBase_2::Geom_traits</i>	A type for the geometric traits that defines the site stored. <i>Precondition:</i> The type <i>Geom_traits</i> must define the type <i>Site_2</i> .
<i>ApolloniusGraphVertexBase_2::Store_hidden</i>	A Boolean that indicates if hidden sites are actually stored or not. Its value is <i>true</i> if hidden sites are stored, <i>false</i> otherwise.
<i>ApolloniusGraphVertexBase_2::Site_2</i>	A type for the site stored. <i>Precondition:</i> This type must coincide with the type <i>Geom_traits::Site_2</i> .
<i>ApolloniusGraphVertexBase_2::Apollonius_graph_data_structure_2</i>	A type for the Apollonius graph data structure, to which the vertex belongs to.
<i>ApolloniusGraphVertexBase_2::Vertex_handle</i>	A type for the vertex handle of the Apollonius graph data structure.
<i>ApolloniusGraphVertexBase_2::Face_handle</i>	A type for the face handle of the Apollonius graph data structure.
<i>ApolloniusGraphVertexBase_2::Hidden_sites_iterator</i>	An iterator that iterates over the hidden sites in the hidden sites container of the vertex. <i>Precondition:</i> Must be a model of <i>Iterator</i> .

Creation

<i>ApolloniusGraphVertexBase_2</i> <i>v</i> ;	Default constructor.
<i>ApolloniusGraphVertexBase_2</i> <i>v</i> (<i>Site_2</i> <i>s</i>);	Constructs a vertex associated with the Apollonius site <i>s</i> and embedded at the center of <i>s</i> .
<i>ApolloniusGraphVertexBase_2</i> <i>v</i> (<i>Site_2</i> <i>s</i> , <i>Face_handle</i> <i>f</i>);	Constructs a vertex associated with the site <i>s</i> , embedded at the center of <i>s</i> , and pointing to the face associated with the face handle <i>f</i> .

Access Functions

<i>Site_2</i>	<i>v.site()</i>	Returns the Apollonius site.
<i>Face_handle</i>	<i>v.face()</i>	Returns a handle to an incident face.
<i>unsigned int</i>	<i>v.number_of_hidden_sites()</i>	Returns the number of hidden sites in the hidden sites container.

<i>Hidden_sites_iterator</i>	<i>v.hidden_sites_begin()</i>	Starts at an arbitrary hidden site.
<i>Hidden_sites_iterator</i>	<i>v.hidden_sites_end()</i>	Past-the-end iterator.

Setting and unsetting

<i>void</i>	<i>v.set_site(Site_2 s)</i>	Sets the Apollonius site.
<i>void</i>	<i>v.set_face(Face_handle f)</i>	Sets the incident face.
<i>void</i>	<i>v.add_hidden_site(Site_2 s)</i>	Adds a hidden site to the container of hidden sites.
<i>void</i>	<i>v.clear_hidden_sites_container()</i>	Clears the container of hidden sites.

Checking

bool

<i>v.is_valid(bool verbose, int level)</i>	Performs any required tests on a vertex.

CGAL::Apollonius_graph_vertex_base_2<Gt,StoreHidden>

CGAL::Apollonius_graph_vertex_base_2<Gt,StoreHidden>

Definition

The class *Apollonius_graph_vertex_base_2<Gt,StoreHidden>* provides a model for the *ApolloniusGraphVertexBase_2* concept which is the vertex base required by the *ApolloniusGraphDataStructure_2* concept. The class *Apollonius_graph_vertex_base_2<Gt,StoreHidden>* has two template arguments, the first being the geometric traits of the Apollonius graph and should be a model of the concept *ApolloniusGraphTraits_2*. The second is a Boolean which controls whether hidden sites are actually stored. Such a control is important if the user is not interested in hidden sites and/or if only insertions are made, in which case no hidden site can become visible. If *StoreHidden* is set to *true*, hidden sites are stored, otherwise they are discarded. By default *StoreHidden* is set to *true*.

```
#include <CGAL/Apollonius_graph_vertex_base_2.h>
```

Is Model for the Concepts

ApolloniusGraphVertexBase_2

Creation

<i>Apollonius_graph_vertex_base_2<Gt,StoreHidden></i> vb;	Default constructor.
<i>Apollonius_graph_vertex_base_2<Gt,StoreHidden></i> vb(<i>Site_2</i> s);	Constructs a vertex associated with the site <i>s</i> and embedded at the center of <i>s</i> .
<i>Apollonius_graph_vertex_base_2<Gt,StoreHidden></i> vb(<i>Site_2</i> s, <i>Face_handle</i> f);	Constructs a vertex associated with the site <i>s</i> , embedded at the center of <i>s</i> , and pointing to the face associated with the face handle <i>f</i> .

ApolloniusGraphTraits_2

Definition

The concept *ApolloniusGraphTraits_2* provides the traits requirements for the *Apollonius_graph_2* class. In particular, it provides a type *Site_2*, which must be a model of the concept *ApolloniusSite_2*. It also provides constructions for sites and several function object types for the predicates.

Types

<i>ApolloniusGraphTraits_2:: Point_2</i>	A type for a point.
<i>ApolloniusGraphTraits_2:: Site_2</i>	A type for an Apollonius site. Must be a model of the concept <i>ApolloniusSite_2</i> .
<i>ApolloniusGraphTraits_2:: Line_2</i>	A type for a line. Only required if access to the dual of the Apollonius graph is required or if the primal or dual diagram are inserted in a stream.
<i>ApolloniusGraphTraits_2:: Ray_2</i>	A type for a ray. Only required if access to the dual of the Apollonius graph is required or if the primal or dual diagram are inserted in a stream.
<i>ApolloniusGraphTraits_2:: Segment_2</i>	A type for a segment. Only required if access to the dual of the Apollonius graph is required or if the primal or dual diagram are inserted in a stream.
<i>ApolloniusGraphTraits_2:: Object_2</i>	A type representing different types of objects in two dimensions, namely: <i>Point_2</i> , <i>Site_2</i> , <i>Line_2</i> , <i>Ray_2</i> and <i>Segment_2</i> .
<i>ApolloniusGraphTraits_2:: FT</i>	A type for the field number type of sites.
<i>ApolloniusGraphTraits_2:: RT</i>	A type for the ring number type of sites.
<i>ApolloniusGraphTraits_2:: Assign_2</i>	Must provide <i>template <class T> bool operator() (T& t, Object_2 o)</i> which assigns <i>o</i> to <i>t</i> if <i>o</i> was constructed from an object of type <i>T</i> . Returns <i>true</i> , if the assignment was possible.
<i>ApolloniusGraphTraits_2:: Construct_object_2</i>	Must provide <i>template <class T> Object_2 operator()(T t)</i> that constructs an object of type <i>Object_2</i> that contains <i>t</i> and returns it.
<i>ApolloniusGraphTraits_2:: Construct_Apollonius_vertex_2</i>	A constructor for a point of the Apollonius diagram equidistant from three sites. Must provide <i>Point_2 operator()(Site_2 s1, Site_2 s2, Site_2 s3)</i> , which constructs a point equidistant from the sites <i>s1</i> , <i>s2</i> and <i>s3</i> .
<i>ApolloniusGraphTraits_2:: Construct_Apollonius_site_2</i>	A constructor for a dual Apollonius site (a site whose center is a vertex of the Apollonius diagram and its weight is the common distance of its center from the three defining sites). Must provide <i>Site_2 operator()(Site_2 s1, Site_2 s2, Site_2 s3)</i> , which constructs a dual site whose center <i>c</i> is equidistant from <i>s1</i> , <i>s2</i> and <i>s3</i> , and its weight is equal to the (signed) distance of <i>c</i> from <i>s1</i> (or <i>s2</i> or <i>s3</i>). Must also provide <i>Line_2 operator()(Site_2 s1, Site_2 s2)</i> , which constructs a line bitangent to <i>s1</i> and <i>s2</i> . This line is the dual site of <i>s1</i> , <i>s2</i> and the site at infinity; it can be viewed as a dual Apollonius site whose center is at infinity and its weight is infinite.

ApolloniusGraphTraits_2:: Compare_x_2

A predicate object type. Must provide *Comparison_result operator()(Site_2 s1, Site_2 s2)*, which compares the x-coordinates of the centers of *s1* and *s2*.

ApolloniusGraphTraits_2:: Compare_y_2

A predicate object type. Must provide *Comparison_result operator()(Site_2 s1, Site_2 s2)*, which compares the y-coordinates of the centers of *s1* and *s2*.

ApolloniusGraphTraits_2:: Compare_weight_2

A predicate object type. Must provide *Comparison_result operator()(Site_2 s1, Site_2 s2)*, which compares the weights of *s1* and *s2*.

ApolloniusGraphTraits_2:: Orientation_2

A predicate object type. Must provide *Orientation operator()(Site_2 s1, Site_2 s2, Site_2 s3)*, which performs the usual orientation test for the centers of the three sites *s1*, *s2* and *s3*.

Must also provide *Orientation operator()(Site_2 s1, Site_2 s2, Site_2 s3, Site_2 p1, Site_2 p2)*, which performs the usual orientation test for the Apollonius vertex of *s1*, *s2*, *s3* and the centers of *p1* and *p2*.

Precondition: the Apollonius vertex of *s1*, *s2* and *s3* must exist.

ApolloniusGraphTraits_2:: Is_hidden_2

A predicate object type. Must provide *bool operator()(Site_2 s1, Site_2 s2)*, which returns *true* if the circle corresponding to *s2* is contained in the closure of the disk corresponding to *s1*, *false* otherwise.

ApolloniusGraphTraits_2:: Oriented_side_of_bisector_2

A predicate object type. Must provide *Oriented_side operator()(Site_2 s1, Site_2 s2, Point_2 p)*, which returns the oriented side of the bisector of *s1* and *s2* that contains *p*. Returns *ON_POSITIVE_SIDE* if *p* lies in the half-space of *s1* (i.e., *p* is closer to *s1* than *s2*); returns *ON_NEGATIVE_SIDE* if *p* lies in the half-space of *s2*; returns *ON_ORIENTED_BOUNDARY* if *p* lies on the bisector of *s1* and *s2*.

ApolloniusGraphTraits_2:: Vertex_conflict_2

A predicate object type. Must provide *Sign operator()(Site_2 s1, Site_2 s2, Site_2 s3, Site_2 q)*, which returns the sign of the distance of *q* from the dual Apollonius site of *s1*, *s2*, *s3*.

Precondition: the dual Apollonius site of *s1*, *s2*, *s3* must exist.

Must also provide *Sign operator()(Site_2 s1, Site_2 s2, Site_2 q)*, which returns the sign of the distance of *q* from the bitangent line of *s1*, *s2* (a degenerate dual Apollonius site, with its center at infinity).

ApolloniusGraphTraits_2:: Finite_edge_interior_conflict_2

A predicate object type. Must provide *bool operator()(Site_2 s1, Site_2 s2, Site_2 s3, Site_2 s4, Site_2 q, bool b)*. The sites $s1$, $s2$, $s3$ and $s4$ define an Apollonius edge that lies on the bisector of $s1$ and $s2$ and has as endpoints the Apollonius vertices defined by the triplets $s1, s2, s3$ and $s1, s4, s2$. The Boolean b denotes if the two Apollonius vertices are in conflict with the site q (in which case b should be *true*, otherwise *false*). In case that b is *true*, the predicate returns *true* if and only if the entire Apollonius edge is in conflict with q . If b is *false*, the predicate returns *false* if and only if q is not in conflict with the Apollonius edge.

Precondition: the Apollonius vertices of $s1, s2, s3$, and $s1, s4, s2$ must exist.

Must also provide *bool operator()(Site_2 s1, Site_2 s2, Site_2 s3, Site_2 q, bool b)*. The sites $s1, s2, s3$ and the site at infinity s_∞ define an Apollonius edge that lies on the bisector of $s1$ and $s2$ and has as endpoints the Apollonius vertices defined by the triplets $s1, s2, s3$ and $s1, s_\infty, s2$ (the second Apollonius vertex is actually at infinity). The Boolean b denotes if the two Apollonius vertices are in conflict with the site q (in which case b should be *true*, otherwise *false*). In case that b is *true*, the predicate returns *true* if and only if the entire Apollonius edge is in conflict with q . If b is *false*, the predicate returns *false* if and only if q is not in conflict with the Apollonius edge.

Precondition: the Apollonius vertex of $s1, s2, s3$ must exist.

Must finally provide *bool operator()(Site_2 s1, Site_2 s2, Site_2 q, bool b)*. The sites $s1, s2$ and the site at infinity s_∞ define an Apollonius edge that lies on the bisector of $s1$ and $s2$ and has as endpoints the Apollonius vertices defined by the triplets $s1, s2, s_\infty$ and $s1, s_\infty, s2$ (both Apollonius vertices are actually at infinity). The Boolean b denotes if the two Apollonius vertices are in conflict with the site q (in which case b should be *true*, otherwise *false*). In case that b is *true*, the predicate returns *true* if and only if the entire Apollonius edge is in conflict with q . If b is *false*, the predicate returns *false* if and only if q is not in conflict with the Apollonius edge.

ApolloniusGraphTraits_2:: Infinite_edge_interior_conflict_2

A predicate object type. Must provide *bool operator()(Site_2 s1, Site_2 s2, Site_2 s3, Site_2 q, bool b)*. The sites $s_\infty, s1, s2$ and $s3$ define an Apollonius edge that lies on the bisector of s_∞ and $s1$ and has as endpoints the Apollonius vertices defined by the triplets $s_\infty, s1, s2$ and $s_\infty, s3, s1$. The Boolean b denotes if the two Apollonius vertices are in conflict with the site q (in which case b should be *true*, otherwise *false*). In case that b is *true*, the predicate returns *true* if and only if the entire Apollonius edge is in conflict with q . If b is *false*, the predicate returns *false* if and only if q is not in conflict with the Apollonius edge.

ApolloniusGraphTraits_2:: Is_degenerate_edge_2

A predicate object type. Must provide *bool operator()(Site_2 s1, Site_2 s2, Site_2 s3, Site_2 s4)*. It returns *true* if the Apollonius edge defined by $s1, s2, s3$ and $s4$ is degenerate, *false* otherwise. An Apollonius edge is called degenerate if its two endpoints coincide.

Precondition: the Apollonius vertices of $s1, s2, s3$, and $s1, s4, s2$ must exist.

CGAL::Apollonius_graph_traits_2<K,Method_tag>

Definition

The class *Apollonius_graph_traits_2<K,Method_tag>* provides a model for the *ApolloniusGraphTraits_2* concept. This class has two template parameters. The first template parameter must be a model of the *Kernel* concept. The second template parameter corresponds to how predicates are evaluated. There are two predefined possible values for *Method_tag*, namely *CGAL::Sqrt_field_tag* and *CGAL::Ring_tag*. The first one must be used when the number type used in the representation supports the exact evaluation of signs of expressions involving all four basic operations and square roots, whereas the second one requires the exact evaluation of signs of ring-type expressions, i.e., expressions involving only additions, subtractions and multiplications. The default value for *Method_tag* is *CGAL::Ring_tag*. The way the predicates are evaluated is discussed in [KE02, KE03].

CGAL::Apollonius_graph_filtered_traits_2<CK,CM,EK,EM,FK,FM>

Definition

The class *Apollonius_graph_filtered_traits_2*<CK,CM,EK,EM,FK,FM> provides a model for the *ApolloniusGraphTraits_2* concept.

The class *Apollonius_graph_filtered_traits_2*<CK,CM,EK,EM,FK,FM> uses the filtering technique [BBP01] to achieve traits for the *Apollonius_graph_2*<Gt,Agds> class with efficient and exact predicates given an exact kernel *EK* and a filtering kernel *FK*. The geometric constructions associated provided by this class are equivalent to those provided by the traits class *Apollonius_graph_traits_2*<CK,CM>, which means that they may be inexact.

This class has six template parameters. The first, third and fifth template parameters must be a models of the *Kernel* concept. The second, fourth and sixth template parameters correspond to how predicates are evaluated. There are two predefined possible values for *Method_tag*, namely *CGAL::Sqrt_field_tag* and *CGAL::Ring_tag*. The first one must be used when the number type used in the representation supports the exact evaluation of signs of expressions involving all four basic operations and square roots, whereas the second one requires the exact evaluation of signs of ring-type expressions, i.e., expressions involving only additions, subtractions and multiplications. The way the predicates are evaluated is discussed in [KE02, KE03].

The default values for the template parameters are as follows: *CM* = *CGAL::Ring_tag*, *EK* = *CGAL::Simple_cartesian*<*CGAL::MP_Float*>, *EM* = *CM*, *FK* = *CGAL::Simple_cartesian*<*CGAL::Interval_nt*<false> >, *FM* = *CM*.

CGAL::Apollonius_graph_hierarchy_2<Gt,Agds>

Definition

We provide an alternative to the class *Apollonius_graph_2<Gt,Agds>* for the dynamic construction of the Apollonius graph. The *Apollonius_graph_hierarchy_2<Gt,Agds>* class maintains a hierarchy of Apollonius graphs. The bottom-most level of the hierarchy contains the full Apollonius diagram. A site that is in level i , is in level $i + 1$ with probability $1/\alpha$ where $\alpha > 1$ is some constant. The difference between the *Apollonius_graph_2<Gt,Agds>* class and the *Apollonius_graph_hierarchy_2<Gt,Agds>* is on how the nearest neighbor location is done. Given a point p the location is done as follows: at the top most level we find the nearest neighbor of p as in the *Apollonius_graph_2<Gt,Agds>* class. At every subsequent level i we use the nearest neighbor found at level $i + 1$ to find the nearest neighbor at level i . This is a variant of the corresponding hierarchy for points found in [Dev98]. The class has two template parameters which have essentially the same meaning as in the *Apollonius_graph_2<Gt,Agds>* class. The first template parameter must be a model of the *ApolloniusGraphTraits_2* concept. The second template parameter must be a model of the *ApolloniusGraphDataStructure_2* concept. However, the vertex base class that is to be used in the Apollonius graph data structure must be a model of the *ApolloniusGraphHierarchyVertexBase_2* concept. The second template parameter defaults to *Triangulation_data_structure_2< Apollonius_graph_hierarchy_vertex_base_2< Apollonius_graph_vertex_base_2<Gt,true> >, Triangulation_face_base_2<Gt> >*.

The *Apollonius_graph_hierarchy_2<Gt,Agds>* class derives publicly from the *Apollonius_graph_2<Gt,Agds>* class. The interface is the same with its base class. In the sequel only the methods overridden are documented.

```
#include <CGAL/Apollonius_graph_hierarchy_2.h>
```

Inherits From

CGAL::Apollonius_graph_2<Gt,Agds>

Types

Apollonius_graph_hierarchy_2<Gt,Agds> does not introduce other types than those introduced by its base class *Apollonius_graph_2<Gt,Agds>*.

Creation

Apollonius_graph_hierarchy_2<Gt,Agds> *agh*(*Gt* *gt*=*Gt*()); Creates an hierarchy of Apollonius graphs using *gt* as geometric traits.

template< class Input_iterator >
Apollonius_graph_hierarchy_2<Gt,Agds> *agh*(*Input_iterator* *first*, *Input_iterator* *beyond*, *Gt* *gt*=*Gt*());

Creates an Apollonius graph hierarchy using *gt* as geometric traits and inserts all sites in the range [*first*, *beyond*).

Apollonius_graph_hierarchy_2<Gt,Agds> *agh*(*other*); Copy constructor. All faces, vertices and inter-level pointers are duplicated. After the construction, *agh* and *other* refer to two different Apollonius graph hierarchies: if *other* is modified, *agh* is not.

<i>Apollonius_graph_hierarchy_2</i> < <i>Gt,Agds</i> >	<i>agh</i> = <i>other</i>	Assignment. All faces, vertices and inter-level pointers are duplicated. After the construction, <i>agh</i> and <i>other</i> refer to two different Apollonius graph hierarchies: if <i>other</i> is modified, <i>agh</i> is not.
--	---------------------------	---

Insertion

```
template< class Input_iterator >
```

```
unsigned int    agh.insert( Input_iterator first, Input_iterator beyond)
```

Inserts the sites in the range [*first*,*beyond*). The number of sites in the range [*first*, *beyond*) is returned.

Precondition: *Input_iterator* must be a model of *InputIterator* and its value type must be *Site_2*.

<i>Vertex_handle</i>	<i>agh.insert(Site_2 s)</i>	Inserts the site <i>s</i> in the Apollonius graph hierarchy. If <i>s</i> is visible then the vertex handle of <i>s</i> is returned, otherwise <i>Vertex_handle(NULL)</i> is returned.
----------------------	------------------------------	---

<i>Vertex_handle</i>	<i>agh.insert(Site_2 s, Vertex_handle vnear)</i>	
----------------------	---	--

Inserts *s* in the Apollonius graph hierarchy using the site associated with *vnear* as an estimate for the nearest neighbor of the center of *s*. If *s* is visible then the vertex handle of *s* is returned, otherwise *Vertex_handle(NULL)* is returned. A call to this method is equivalent to *agh.insert(s)*; and it has been added for the sake of conformity with the interface of the *Apollonius_graph_2*<*Gt,Agds*> class.

Removal

<i>void</i>	<i>agh.remove(Vertex_handle v)</i>	Removes the site associated to the vertex handle <i>v</i> from the Apollonius graph hierarchy. <i>Precondition:</i> <i>v</i> must correspond to a valid finite vertex of the Apollonius graph hierarchy.
-------------	-------------------------------------	---

Nearest neighbor location

<i>Vertex_handle</i>	<i>agh.nearest_neighbor(Point p)</i>	Finds the nearest neighbor of the point <i>p</i> . In other words it finds the site whose Apollonius cell contains <i>p</i> . Ties are broken arbitrarily and one of the nearest neighbors of <i>p</i> is returned. If there are no visible sites in the Apollonius diagram <i>Vertex_handle(NULL)</i> is returned.
----------------------	---------------------------------------	---

<i>Vertex_handle</i>	<i>agh.nearest_neighbor(Point p, Vertex_handle vnear)</i>	
----------------------	--	--

Finds the nearest neighbor of the point *p*. If there are no visible sites in the Apollonius diagram *Vertex_handle(NULL)* is returned. A call to this method is equivalent to *agh.nearest_neighbor(p)*; and it has been added for the sake of conformity with the interface of the *Apollonius_graph_2*<*Gt,Agds*> class.

I/O

<code>void</code>	<code>agh.file_output(std::ostream& os)</code>	Writes the current state of the Apollonius graph hierarchy to an output stream. In particular, all visible and hidden sites are written as well as the underlying combinatorial hierarchical data structure.
<code>void</code>	<code>agh.file_input(std::istream& is)</code>	Reads the state of the Apollonius graph hierarchy from an input stream.
<code>std::ostream&</code>	<code>std::ostream& os << agh</code>	Writes the current state of the Apollonius graph hierarchy to an output stream.
<code>std::istream&</code>	<code>std::istream& is >> agh</code>	Reads the state of the Apollonius graph hierarchy from an input stream.

Validity check

<code>bool</code>	<code>agh.is_valid(bool verbose = false, int level = 1)</code>	Checks the validity of the Apollonius graph hierarchy. If <i>verbose</i> is <i>true</i> a short message is sent to <code>std::cerr</code> . If <i>level</i> is 0, the data structure at all levels is validated, as well as the inter-level pointers. If <i>level</i> is 1, then the data structure at all levels is validated, the inter-level pointers are validated and all levels of the Apollonius graph hierarchy are also validated. Negative values of <i>level</i> always return <i>true</i> , and values greater than 1 are equivalent to <i>level</i> being 1.
-------------------	---	---

Miscellaneous

<code>void</code>	<code>agh.clear()</code>	Clears all contents of the Apollonius graph hierarchy.
<code>void</code>	<code>agh.swap(other)</code>	The Apollonius graph hierarchies <i>other</i> and <i>agh</i> are swapped. <code>agh.swap(other)</code> should be preferred to <code>agh= other</code> or to <code>agh(other)</code> if <i>other</i> is deleted afterwards.

ApolloniusGraphHierarchyVertexBase_2

Definition

The vertex of an Apollonius graph included in an Apollonius graph hierarchy has to provide some pointers to the corresponding vertices in the graphs of the next and preceding levels. Therefore, the concept *ApolloniusGraphHierarchyVertexBase_2* refines the concept *ApolloniusGraphVertexBase_2*, by adding two vertex handles to the corresponding vertices for the next and previous level graphs.

Refines

ApolloniusGraphVertexBase_2

Types

ApolloniusGraphHierarchyVertexBase_2 does not introduce any types in addition to those of *ApolloniusGraphVertexBase_2*.

Creation

ApolloniusGraphHierarchyVertexBase_2 *v*;
ApolloniusGraphHierarchyVertexBase_2 *v*(*Site_2* *s*);

Default constructor.
 Constructs a vertex associated with the site *s* and embedded at the center of *s*.

ApolloniusGraphHierarchyVertexBase_2 *v*(*Site_2* *s*, *Face_handle* *f*);

Constructs a vertex associated with the site *s*, embedded at the center of *s*, and pointing to face *f*.

Operations

<i>Vertex_handle</i>	<i>v.up()</i>	Returns a handle to the corresponding vertex of the next level Apollonius graph. If such a vertex does not exist <i>Vertex_handle(NULL)</i> is returned.
<i>Vertex_handle</i>	<i>v.down()</i>	Returns a handle to the corresponding vertex of the previous level Apollonius graph.
<i>void</i>	<i>v.set_up(Vertex_handle u)</i>	Sets the handle for the vertex of the next level Apollonius graph.
<i>void</i>	<i>v.set_down(Vertex_handle d)</i>	Sets the handle for the vertex of the previous level Apollonius graph;

This chapter describes an adaptor that adapts two-dimensional triangulated Delaunay graphs to the corresponding Voronoi diagrams. We start with a few definitions and a description of the issues that this adaptor addresses in Section [44.1](#). The software design of the Voronoi diagram adaptor package is described in Section [44.2](#). In Section [44.3](#) we discuss the traits required for performing the adaptation, and finally in Section [44.5](#) we present a few examples using this adaptor.

44.1 Introduction

A Voronoi diagram is typically defined for a set of objects, also called sites in the sequel, that lie in some space Σ and a distance function that measures the distance of a point x in Σ from an object in the object set. In this package we are interested in planar Voronoi diagrams, so in the sequel the space Σ will be the space \mathbb{R}^2 . Let $\mathcal{S} = \{S_1, S_2, \dots, S_n\}$ be our set of sites and let $\delta(x, S_i)$ denote the distance of a point $x \in \mathbb{R}^2$ from the site S_i . Given two sites S_i and S_j , the set V_{ij} of points that are closer to S_i than to S_j with respect to the distance function $\delta(x, \cdot)$ is simply the set:

$$V_{ij} = \{x \in \mathbb{R}^2 : \delta(x, S_i) < \delta(x, S_j)\}.$$

We can then define the set V_i of points on the plane that are closer to S_i than to any other object in \mathcal{S} as:

$$V_i = \bigcap_{i \neq j} V_{ij}.$$

The set V_i is said to be the *Voronoi cell* or *Voronoi face* of the site S_i . The locus of points on the plane that are equidistant from exactly two sites S_i and S_j is called a *Voronoi bisector*. A point that is equidistant to three or

more objects in S is called a *Voronoi vertex*. A simply connected subset of a Voronoi bisector is called a *Voronoi edge*. The collection of Voronoi faces, edges and vertices is called the *Voronoi diagram* of the set S with respect to the distance function $\delta(x, \cdot)$, and it turns out that it is a subdivision of the plane, i.e., it is a planar graph.

We typically think of faces as 2-dimensional objects, edges as 1-dimensional objects and vertices as 0-dimensional objects. However, this may not be the case for several combinations of sites and distance functions (for example points in \mathbb{R}^2 under the L_1 or the L_∞ distance can produce 2-dimensional Voronoi edges). We call a Voronoi diagram *nice* if no such artifacts exist, i.e., if all vertices edges and faces are 0-, 1- and 2-dimensional, respectively.

Even nice Voronoi diagrams can end up being not so nice. The cell of a site can in general consist of several disconnected components. Such a case can happen, for example, when we consider weighted points $Q_i = (p_i, \lambda_i)$, where $p_i \in \mathbb{R}^2$, $\lambda_i \in \mathbb{R}$, and the distance function is the Euclidean distance multiplied by the weight of each site, i.e., $\delta_M(x, Q_i) = \lambda_i \|x - p_i\|$, where $\|\cdot\|$ denotes the Euclidean norm. In this package we are going to restrict ourselves to nice Voronoi diagrams that have the property that the Voronoi cell of each site is a simply connected region of the plane. We are going to call such Voronoi diagrams *simple Voronoi diagrams*. Examples of simple Voronoi diagrams include the usual Euclidean Voronoi diagram of points, the Euclidean Voronoi diagram of a set of disks on the plane (i.e., the Apollonius diagram), the Euclidean Voronoi diagram of a set of disjoint convex objects on the plane, or the power or (Laguerre) diagram for a set of circles on the plane. In fact every instance of an *abstract Voronoi diagram* in the sense of Klein [Kle89] is a simple Voronoi diagram in our setting. In the sequel when we refer to Voronoi diagrams we will refer to simple Voronoi diagrams.

In many cases we are not really interested in computing the Voronoi diagram itself, but rather its dual graph, called the *Delaunay graph*. In general the Delaunay graph is a planar graph, each face of which consists of at least three edges. Under the non-degeneracy assumption that no point on the plane is equidistant, under the distance function, to more than three sites, the Delaunay graph is a planar graph with triangular faces. In certain cases this graph can actually be embedded with straight line segments in which case we talk about a triangulation. This is the case, for example, for the Euclidean Voronoi diagram of points, or the power diagram of a set of circles. The dual graphs are, respectively, the Delaunay triangulation and the regular triangulation of the corresponding site sets. Graphs of non-constant non-uniform face complexity can be undesirable in many applications, so typically we end up triangulating the non-triangular faces of the Delaunay graph. Intuitively this amounts to imposing an implicit or explicit perturbation scheme during the construction of the Delaunay graph, that perturbs the input sites in such a way so as not to have degenerate configurations.

Choosing between computing the Voronoi diagram or the (triangulated) Delaunay graph is a major decision while implementing an algorithm. It heavily affects the design and choice of the different data structures involved. Although in theory the two approaches are entirely equivalent, it is not so straightforward to go from one representation to the other. The objective of this package is to provide a generic way of going from triangulated Delaunay graphs to planar subdivisions represented through a DCEL data structure. The goal is to provide an adaptor that gives the look and feel of a DCEL data structure, although internally it keeps a graph data structure representing triangular graphs.

The adaptation might seem straightforward at a first glance, and more or less this is case; after all one graph is the dual of the other. The situation becomes complicated whenever we want to treat artifacts of the representation used. Suppose for example that we have a set of sites that contains subsets of sites in degenerate positions. The computed triangulated Delaunay graph has triangular faces that may be the result of an implicit or explicit perturbation scheme. The dual of such a triangulated Delaunay graph is a Voronoi diagram that has all its vertices of degree 3, and for that purpose we are going to call it a *degree-3 Voronoi diagram* in order to distinguish it from the true Voronoi diagram of the input sites. A degree-3 Voronoi diagram can have degenerate features, namely Voronoi edges of zero length, and/or Voronoi faces of zero area. Although we can potentially treat such artifacts, they are nonetheless artifacts of the algorithm we used and do not correspond to the true geometry of the Voronoi diagram.

The manner that we treat such issues in this package in a generic way is by defining an *adaptation policy*. The adaptation policy is responsible for determining which features in the degree-3 Voronoi diagram are to be

rejected and which not. The policy to be used can vary depending on the application or the intended usage of the resulting Voronoi diagram. What we care about is that firstly the policy itself is consistent and, secondly, that the adaptation is also done in a consistent manner. The latter is the responsibility of the adaptor provided by this package, whereas the former is the responsibility of the implementor of a policy.

In this package we currently provide two types of adaptation policies. The first one is the simplest: we reject no feature of the degree-3 Voronoi diagram; we call such a policy an *identity policy* since the Voronoi diagram produced is identical to the degree-3 Voronoi diagram. The second type of policy eliminates the degenerate features from the degree-3 Voronoi diagram yielding the true geometry of the Voronoi diagram of the input sites; we call such policies *degeneracy removal policies*.

Delaunay graphs can be mutable or non-mutable. By mutable we mean that sites can be inserted or removed at any time, in an entirely on-line fashion. By non-mutable we mean that once the Delaunay graph has been created, no changes, with respect to the set of sites defining it, are allowed. If the Delaunay graph is a non-mutable one, then the Voronoi diagram adaptor is a non-mutable adaptor as well.

If the Delaunay graph is mutable then the question of whether the Voronoi diagram adaptor is also mutable is slightly more complex to answer. As long as the adaptation policy used does not maintain a state, the Voronoi diagram adaptor is a mutable one; this is the case, for example, with our identity policy or the degeneracy removal policies. If, however, the adaptor maintains a state, then whether it is mutable or non-mutable really depends on whether its state can be updated after every change in the Delaunay graph. Such policies are our caching degeneracy removal policies: some of them result in mutable adaptors others result in non-mutable ones. In Section 44.4 we discuss the issue in more detail.

44.2 Software Design

The *Voronoi_diagram_2*<*DG,AT,AP*> class is parameterized by three template parameters. The first one must be a model of the *DelaunayGraph_2* concept. It corresponds to the API required by an object representing a Delaunay graph. All classes of CGAL that represent Delaunay diagrams are models of this concept, namely, Delaunay triangulations, regular triangulations, Apollonius graphs and segment Delaunay graphs. The second template parameter must be a model of the *AdaptationTraits_2* concept. We discuss this concept in detail in Section 44.3. The third template parameter must be model of the *AdaptationPolicy_2* concept, which we discuss in detail in Section 44.4.

The *Voronoi_diagram_2*<*DG,AT,AP*> class has been intentionally designed to provide an API similar to the arrangements class in CGAL: Voronoi diagrams are special cases of arrangements after all. The API of the two classes, however, could not be identical. The reason is that arrangements in CGAL do not yet support more than one unbounded faces, or equivalently, cannot handle unbounded curves. On the contrary, a Voronoi diagram defined over at least two generating sites, has at least two unbounded faces.

On a more technical level, the *Voronoi_diagram_2*<*DG,AT,AP*> class imitates the representation of the Voronoi diagram (seen as a planar subdivision) by a DCEL (Doubly Connected Edge List) data structure. We have vertices (the Voronoi vertices), halfedges (oriented versions of the Voronoi edges) and faces (the Voronoi cells). In particular, we can basically perform every operation we can perform in a standard DCEL data structure:

- go from a halfedge to its next and previous in the face;
- go from one face to an adjacent one through a halfedge and its twin (opposite) halfedge;
- walk around the boundary of a face;
- enumerate/traverse the halfedges incident to a vertex
- from a halfedge, access the adjacent face;

- from a face, access an adjacent halfedges;
- from a halfedges, access its source and target vertices;
- from a vertex, access an incident halfedge.

In addition to the above possibilities for traversal, we can also traverse the following features through iterators:

- the vertices of the Voronoi diagram;
- the edges or halfedges of the Voronoi diagram;
- the faces of the Voronoi diagram;
- the bounded faces of the Voronoi diagram;
- the bounded halfedges of the Voronoi diagram;
- the unbounded faces of the Voronoi diagram;
- the unbounded halfedges of the Voronoi diagram;
- the sites defining the Voronoi diagram.

Finally, depending on the adaptation traits passed to the Voronoi diagram adaptor, we can perform point location queries, namely given a point p we can determine the feature of the Voronoi diagram (vertex, edge, face) on which p lies.

44.3 The Adaptation Traits

The *AdaptationTraits_2* concept defines the types and functor required by the adaptor in order to access geometric information in the Delaunay graph that is needed by the *Voronoi_diagram_2<DG,AT,AP>* class. In particular, it provides functors for accessing sites in the Delaunay graph and constructing Voronoi vertices from their dual faces in the Delaunay graph. Finally, it defines a tag that indicates whether nearest site queries are to be supported by the Voronoi diagram adaptor. If such queries are to be supported, a functor is required.

Given a query point, the nearest site functor should return information related to how many and which sites of the Voronoi diagram are at equal and minimal distance from the query point. In particular, if the query point is closest to a single site, the vertex handle of the Delaunay graph corresponding to this site is returned. If the query point is closest to exactly two site, the edge of the Delaunay graph that is dual to the Voronoi edges on which the query point lies is returned. If three (or more) sites are closest to the query point, then the query point coincides with a vertex in the Voronoi diagram, and the face handle of the face in the Delaunay graph that is dual to the Voronoi vertex is returned. This way of abstracting the point location mechanism allows for multiple different point location strategies, which are passed to the Voronoi diagram adaptor through different models of the *AdaptationTraits_2* concept. The point location and nearest sites queries of the *Voronoi_diagram_2<DG,AT,AP>* class use internally this nearest site query functor.

In this package we provide four adaptation traits classes, all of which support nearest site queries:

- The *Apollonius_graph_adaptation_traits_2<AG2>* class: it provides the adaptation traits for Apollonius graphs.
- The *Delaunay_triangulation_adaptation_traits_2<DT2>* class: it provides the adaptation traits for Delaunay triangulations.

- The *Regular_triangulation_adaptation_traits_2<RT2>* class: it provides the adaptation traits for regular triangulations.
- The *Segment_Delaunay_graph_adaptation_traits_2<SDG2>* class: it provides the adaptation traits for segment Delaunay graphs.

44.4 The Adaptation Policy

As mentioned above, when we perform the adaptation of a triangulated Delaunay graph to a Voronoi diagram, a question that arises is whether we want to eliminate certain features of the Delaunay graph when we construct its Voronoi diagram representation (such features could be the Voronoi edges of zero length or, for the Voronoi diagram of a set of segments forming a polygon, all edges outside the polygon). The manner that we treat such issues in this package in a generic way is by defining an adaptation policy. The adaptation policy is responsible for determining which features in the degree-3 Voronoi diagram are to be rejected and which not. The policy to be used can vary depending on the application or the intended usage of the resulting Voronoi diagram.

The concept *AdaptationPolicy_2* defines the requirements on the predicate functors that determine whether a feature of the triangulated Delaunay graph should be rejected or not. More specifically it defines an *Edge_rejector* and a *Face_rejector* functor that answer the question: “should this edge (face) of the Voronoi diagram be rejected?”. In addition to the edge and face rejectors the adaptation policy defines a tag, the *Has_inserter* tag. This tag is either set to *CGAL::Tag_true* or to *CGAL::Tag_false*. Semantically it determines if the adaptor is allowed to insert sites in an on-line fashion (on-line removals are not yet supported). In the former case, i.e., when on-line site insertions are allowed, an additional functor is required, the *Site_inserter* functor. This functor takes a reference to a Delaunay graph and a site, and inserts the site in the Delaunay graph. Upon successful insertion, a handle to the vertex representing the site in the Delaunay graph is returned.

We have implemented two types of policies that provide two different ways for answering the question of which features of the Voronoi diagram to keep and which to discard. The first one is called the *identity policy* and corresponds to the *Identity_policy_2<DG,VT>* class. This policy is in some sense the simplest possible one, since it does not reject any feature of the Delaunay graph. The Voronoi diagram provided by the adaptor is the true dual (from the graph-theoretical point of view) of the triangulated Delaunay graph adapted. This policy assumes that the Delaunay graph adapted allows for on-line insertions, and the *Has_inserter* tag is set to *CGAL::Tag_true*. A default site inserter functor is also provided.

The second type of policy we provide is called *degeneracy removal policy*. If the set of sites defining the triangulated Delaunay graph contains subsets of sites in degenerate configurations, the graph-theoretical dual of the triangulated Delaunay graph has edges and potentially faces that are geometrically degenerate. By that we mean that the dual of the triangulated Delaunay graph can have Voronoi edges of zero length or Voronoi faces/cells of zero area. Such features may not be desirable and ideally we would like to eliminate them. The degeneracy removal policies eliminate exactly these features and provide a Voronoi diagram where all edges have non-zero length and all cells have non-zero area. More specifically, in these policies the *Edge_rejector* and *Face_rejector* functors reject the edges and vertices of the Delaunay graph that correspond to dual edges and faces that have zero length and area, respectively. In this package we provide four degeneracy removal policies, namely:

- The *Apollonius_graph_degeneracy_removal_policy_2<AG2>* class: it provides an adaptation policy for removing degeneracies when adapting an Apollonius graph to an Apollonius diagram.
- The *Delaunay_triangulation_degeneracy_removal_policy_2<DT2>* class: it provides an adaptation policy for removing degeneracies when adapting a Delaunay triangulation to a point Voronoi diagram.
- The *Regular_triangulation_degeneracy_removal_policy_2<RT2>* class: it provides an adaptation policy for removing degeneracies when adapting a regular triangulation to a power diagram

- The *Segment_Delaunay_graph_degeneracy_removal_policy_2<SDG2>* class: it provides an adaptation policy for removing degeneracies when adapting a segment Delaunay graph to a segment Voronoi diagram.

A variation of the degeneracy removal policies are the *caching degeneracy removal policies*. In these policies we cache the results of the edge and face rejectors. In particular, every time we want to determine, for example, if an edge of the Delaunay graph has, as dual edge in the Voronoi diagram, an edge of zero length, we check if the result has already been computed. If yes, we simply return the outcome. If not, we perform the necessary geometric tests, compute the answer, cache it and return it. Such a policy really pays off when we have a lot of degenerate data in our input set of sites. Verifying whether a Voronoi edge is degenerate or not implies computing the outcome of a predicate in a possibly degenerate or near degenerate configuration, which is typically very costly (compared to computing the same predicate in a generic configuration). To avoid this cost every single time we want to check if a Voronoi edge is degenerate or not, we compute the result of the geometric predicate the first time the adaptor asks for it, and simply lookup the answer in the future. In this package we provide four caching degeneracy removal policies, one per degeneracy removal policy mentioned above. Intentionally, we have not indicated the value of the *Has_inserter* tag for the degeneracy removal and caching degeneracy removal policies. The issue is discussed in detail in the sequel.

We raised the question above, as to whether the adaptor is a mutable or non-mutable one, in the sense of whether we can add/remove sites in an on-line fashion. The answer to this question depends on: (1) whether the Delaunay graph adapted allows for on-line insertions/removals and (2) whether the adaptation policies maintains a state and whether this state is easily maintainable when we want to allow for on-line modifications.

The way we indicate if we allow on-line insertions of sites is via the *Has_inserter* tag (as mentioned, on-line removals are currently not supported). The *Has_inserter* tag has two possible values, namely, *CGAL::Tag_true* and *CGAL::Tag_false*. The value *CGAL::Tag_true* indicates that the Delaunay graph allows for on-line insertions, whereas the value *CGAL::Tag_false* indicates the opposite. Note that these values *do not* indicate if the Delaunay graph supports on-line insertions, but rather whether the Voronoi diagram adaptor should be able to perform on-line insertions or not. This delicate point will become clearer below.

Let us consider the various scenarios. If the Delaunay graph is non-mutable, the Voronoi diagram adaptor cannot perform on-line insertions of sites. In this case not only degeneracy removal policies, but rather every single adaptation policy for adapting the Delaunay graph in question should have the *Has_inserter* tag set to *CGAL::Tag_false*.

If the Delaunay graph is mutable, i.e., on-line site insertions are allowed, we can choose between two types of adaptation policies, those that allow these on-line insertions and those that do not. In the former case the *Has_inserter* tag should be set to *CGAL::Tag_true*, whereas in the latter to *CGAL::Tag_false*. In other words, even if the Delaunay graph is mutable, we can choose (by properly determining the value of the *Has_inserter* tag) if the adaptor should be mutable as well. At a first glance it may seem excessive to restrict existing functionality. There are situations, however, where such a choice is necessary.

Consider a caching degeneracy removal policy. If we do not allow for on-line insertions then the cached quantities are always valid since the Voronoi diagram never changes. If we allow for on-line insertions the Voronoi diagram can change, which implies that the results of the edge and faces degeneracy testers that we have cached are no longer valid or relevant. In these cases, we need to somehow update these cached results, and ideally we would like to do this in an efficient manner. The inherent dilemma in the above discussion is whether the Voronoi diagram adaptor should be able to perform on-line insertions of sites. The answer to this question in this framework is given by the *Has_inserter* tag. If the tag is set to *CGAL::Tag_false* the adaptor cannot insert sites on-line, whereas if the tag is set to *CGAL::Tag_true* the adaptor can add sites on-line. In other words, the *Has_inserter* tag determines how the Voronoi diagram adaptor should behave, and this is enough from the adaptor's point of view.

From the point of view of a policy writer the dilemma is still there: should the policy allow for on-line insertions or not? The answer really depends on what are the consequences of such a choice. For a policy that

has no state, such as our degeneracy removal policies, it is natural to set the *Has_inserter* tag to *CGAL::Tag_true*. For our caching degeneracy removal policies, our choice was made on the grounds of whether we can update the cached results efficiently when insertions are performed. For CGAL's Apollonius graphs, Delaunay triangulation and regular triangulations it is possible to ask what are the edges and faces of the Delaunay graph that are to be destroyed when a query site is inserted. This is done via the *get_conflicts* method provided by these classes. Using the outcome of the *get_conflicts* method the site inserter can first update the cached results (i.e., indicate which are invalidated) and then perform the actual insertion. Such a method does not yet exist for segment Delaunay graphs. We have thus chosen to support on-line insertions for all non-caching degeneracy removal policies. The caching degeneracy removal policy for segment Delaunay graphs does not support on-line insertions, whereas the remaining three caching degeneracy removal policies support on-line insertions.

Efficiency Considerations

One last item that merits some discussion are the different choices from the point of view of time- and space-efficiency.

As far as the Voronoi diagram adaptor is concerned, only a copy of the adaptation traits and a copy of the adaptation policy are stored in it. The various adaptation traits classes we provide are empty classes (i.e., they do not store anything). The major time and space efficiency issues arise from the various implementations of the adaptation policies. Clearly, the identity policy has no dominant effect on neither the time or space efficiency. The costs when choosing this policy are due to the underlying Delaunay graph.

The non-caching degeneracy removal policies create a significant time overhead since every time we want to access a feature of the Voronoi diagram, we need to perform geometric tests in order to see if this feature or one of its neighboring ones has been rejected. Such a policy is acceptable if we know we are away from degeneracies or for small input sizes. In the case of the segment Delaunay graph, it is also the only policy we provide that at the same time removes degeneracies and allows for on-line insertion of sites. Caching policies seem to be the best choice for moderate to large input sizes (1000 sites and more). They do not suffer from the problem of dealing with degenerate configurations, but since they cache the results, they increase the space requirements by linear additive factor. To conclude, if the user is interested in getting a Voronoi diagram without degenerate features and knows all sites in advance, the best course of action is to insert all sites at construction time and use a caching degeneracy removal policy. This strategy avoids the updates of the cached results after each individual insertion, due to the features of the Voronoi diagram destroyed because of the site inserted.

44.5 Examples

In this section we present an example that shows how to perform point location queries.

```
#include <CGAL/basic.h>

// standard includes
#include <iostream>
#include <fstream>
#include <cassert>

// includes for defining the Voronoi diagram adaptor
#include <CGAL/Exact_predicates_inexact_constructions_kernel.h>
#include <CGAL/Delaunay_triangulation_2.h>
#include <CGAL/Voronoi_diagram_2.h>
#include <CGAL/Delaunay_triangulation_adaptation_traits_2.h>
#include <CGAL/Delaunay_triangulation_adaptation_policies_2.h>
```

```

2D Voronoi Diagram Adaptor Reference Manual

Menelaos Karavelas

CGAL provides the class `CGAL::Voronoi_diagram_2<DG,AT,AP>` for adapting the various (triangulated) Delaunay graphs to Voronoi diagrams according to some adaptation policy. In particular, the class `CGAL::Voronoi_diagram_2<DG,AT,AP>` provides an API for the duals of (triangulated) Delaunay graphs, that makes them look like planar subdivisions. The adaptation policy is responsible for deciding which edges and faces of these duals should be eliminated. This is especially important when, for instance, we want to eliminate degenerate features in the Voronoi diagram that are the result of the fact that Delaunay graphs are always triangulated and are due to degenerate configurations in the generating data.

The three template parameters must be models of the *DelaunayGraph_2*, *AdaptationTraits_2* and *AdaptationPolicy_2* concepts, respectively. The first concept is related to the Delaunay graphs that are to be adapted, whereas the second one is responsible for manipulating/accessing in a unified way the geometry of a specific Voronoi diagram as well as for performing nearest site queries. The third template parameter corresponds to the chosen adaptation policy and provides the necessary types and functors needed for performing this adaptation.

CGAL::Voronoi_diagram_2<DG,AT,AP>

Definition

The class *Voronoi_diagram_2<DG,AT,AP>* provides an adaptor that enables us to view a triangulated Delaunay graph as their dual subdivision, the Voronoi diagram. The class *Voronoi_diagram_2<DG,AT,AP>* is designed to provide an API that is similar to that of CGAL's arrangements.

The first template parameter of the *Voronoi_diagram_2<DG,AT,AP>* class corresponds to the triangulated Delaunay graph and must be a model of the *DelaunayGraph_2* concept. The second template parameter must be a model of the *AdaptationTraits_2* concept. The third template parameter must be a model of the *AdaptationPolicy_2* concept. The third template parameter defaults to *CGAL::Identity_policy_2<DG,AT>*.

```
#include <CGAL/Voronoi_diagram_2.h>
```

Types

<i>typedef DG</i>	<i>Delaunay_graph;</i>	A type for the dual Delaunay graph.
<i>typedef AT</i>	<i>Adaptation_traits;</i>	A type for the adaptation traits needed by the Voronoi diagram adaptor.
<i>typedef AP</i>	<i>Adaptation_policy;</i>	A type for the adaptation policy used.
<i>typedef Adaptation_traits::Point_2</i>	<i>Point_2;</i>	A type a point.
<i>typedef Adaptation_traits::Site_2</i>	<i>Site_2;</i>	A type for the sites of the Voronoi diagram.
<i>typedef Delaunay_graph::size_type</i>	<i>size_type;</i>	A type for sizes.
<i>typedef Delaunay_graph::Geom_traits</i>	<i>Delaunay_geom_traits;</i>	A type for the geometric traits of the Delaunay graph.
<i>typedef Delaunay_graph::Vertex_handle</i>	<i>Delaunay_vertex_handle;</i>	A type for the vertex handles of the Delaunay graph.
<i>typedef Delaunay_graph::Face_handle</i>	<i>Delaunay_face_handle;</i>	A type for the face handles of the Delaunay graph.
<i>typedef Delaunay_graph::Edge</i>	<i>Delaunay_edge;</i>	A type for the edges of the Delaunay graph.
<i>Voronoi_diagram_2<DG,AT,AP>:: Halfedge</i>	A type for the halfedges of the Voronoi diagram.	
<i>Voronoi_diagram_2<DG,AT,AP>:: Vertex</i>	A type for the vertices of the Voronoi diagram.	
<i>Voronoi_diagram_2<DG,AT,AP>:: Face</i>	A type for the faces of the Voronoi diagram.	

The vertices, edges and faces of the Voronoi diagram are accessed through *handles*, *iterators* and *circulators*. The iterators and circulators are all bidirectional and non-mutable. The circulators and iterators are assignable to the corresponding handle types, and they are also convertible to the corresponding handles.

Voronoi_diagram_2<DG,AT,AP>:: Halfedge_handle Handle for halfedges.

<i>Voronoi_diagram_2<DG,AT,AP>:: Vertex_handle</i>	Handle for vertices.
<i>Voronoi_diagram_2<DG,AT,AP>:: Face_handle</i>	Handle for faces.
<i>Voronoi_diagram_2<DG,AT,AP>:: Edge_iterator</i>	A type for an iterator over Voronoi edges. Edges are considered non-oriented. Its value type is <i>Halfedge</i> .
<i>Voronoi_diagram_2<DG,AT,AP>:: Halfedge_iterator</i>	A type for an iterator over Voronoi halfedges. Halfedges are oriented and come in pairs. Its value type is <i>Halfedge</i> .
<i>Voronoi_diagram_2<DG,AT,AP>:: Face_iterator</i>	A type for an iterator over Voronoi faces. Its value type is <i>Face</i> .
<i>Voronoi_diagram_2<DG,AT,AP>:: Vertex_iterator</i>	A type for an iterator over Voronoi vertices. Its value type is <i>Vertex</i> .
<i>Voronoi_diagram_2<DG,AT,AP>:: Halfedge_around_vertex_circulator</i>	A type for a circulator over the halfedges that have a common vertex as their target. Its value type is <i>Halfedge</i> .
<i>Voronoi_diagram_2<DG,AT,AP>:: Ccb_halfedge_circulator</i>	A type for a circulator over the halfedges on the boundary of a Voronoi face. Its value type of is <i>Halfedge</i> .
<i>Voronoi_diagram_2<DG,AT,AP>:: Unbounded_faces_iterator</i>	A type for an iterator over the unbounded faces of the Voronoi diagram. Its value type is <i>Face</i> .
<i>Voronoi_diagram_2<DG,AT,AP>:: Bounded_faces_iterator</i>	A type for an iterator over the bounded faces of the Voronoi diagram. Its value type is <i>Face</i> .
<i>Voronoi_diagram_2<DG,AT,AP>:: Unbounded_halfedges_iterator</i>	A type for an iterator over the unbounded halfedges of the Voronoi diagram. Its value type is <i>Halfedge</i> .
<i>Voronoi_diagram_2<DG,AT,AP>:: Bounded_halfedges_iterator</i>	A type for an iterator over the bounded halfedges of the Voronoi diagram. Its value type is <i>Halfedge</i> .
<i>Voronoi_diagram_2<DG,AT,AP>:: Site_iterator</i>	A type for an iterator over the sites of the Voronoi diagram. Its value type is <i>Site_2</i> .
<i>typedef boost::variant<Face_handle,Halfedge_handle,Vertex_handle></i>	<i>Locate_result;</i> The result type of the point location queries.

Creation

```
Voronoi_diagram_2<DG,AT,AP> vd( Adaptation_traits at = Adaptation_traits(),
                                Adaptation_policy ap = Adaptation_policy(),
                                Delaunay_geom_traits gt = Delaunay_geom_traits())
```

Creates a Voronoi diagram using *at* as adaptation traits and *ap* as adaptation policy; the underlying Delaunay graph is created using *gt* as geometric traits.

```
Voronoi_diagram_2<DG,AT,AP> vd( Delaunay_graph dg,
                                bool swap_dg = false,
                                Adaptation_traits at = Adaptation_traits(),
                                Adaptation_policy ap = Adaptation_policy())
```

Creates a Voronoi diagram from the Delaunay graph *dg* and using *at* as adaptation traits and *ap* as adaptation policy. The Delaunay graph *dg* is fully copied if *swap_dg* is set to *false*, or swapped with the one stored internally if *swap_dg* is set to *true*.

```
template<class Iterator>
Voronoi_diagram_2<DG,AT,AP> vd( Iterator first,
                                Iterator beyond,
                                Adaptation_traits at = Adaptation_traits(),
                                Adaptation_policy ap = Adaptation_policy(),
                                Delaunay_geom_traits gt = Delaunay_geom_traits())
```

Creates a Voronoi diagram using as sites the sites in the iterator range [*first*, *beyond*), *at* as adaptation traits and *ap* as adaptation policy; the underlying Delaunay graph is created using *gt* as geometric traits. *Iterator* must be a model of the *InputIterator* concept and its value type must be *Site_2*.

Access Methods

<i>Delaunay_graph</i>	<i>vd.dual()</i>	Returns a const reference to the dual graph, i.e., the Delaunay graph.
<i>Halfedge_handle</i>	<i>vd.dual(Delaunay_edge e)</i>	Returns a handle to the halfedge in the Voronoi diagram that is dual to the edge <i>e</i> in the Delaunay graph.
<i>Face_handle</i>	<i>vd.dual(Delaunay_vertex_handle v)</i>	Returns a handle to the face in the Voronoi diagram that is dual to the vertex corresponding to the vertex handle <i>v</i> in the Delaunay graph.
<i>Vertex_handle</i>	<i>vd.dual(Delaunay_face_handle f)</i>	Returns a handle to the vertex in the Voronoi diagram that is dual to the face corresponding to the face handle <i>f</i> in the Delaunay graph.
<i>Adaptation_traits</i>	<i>vd.adaptation_traits()</i>	Returns a reference to the Voronoi traits.
<i>Adaptation_policy</i>	<i>vd.adaptation_policy()</i>	Returns a reference to the adaptation policy.
<i>size_type</i>	<i>vd.number_of_vertices()</i>	Returns the number of Voronoi vertices.
<i>size_type</i>	<i>vd.number_of_faces()</i>	Returns the number of Voronoi faces (bounded and unbounded).
<i>size_type</i>	<i>vd.number_of_halfedges()</i>	Returns the number of halfedges (bounded and unbounded) in the Voronoi diagram. This is always an even number.
<i>size_type</i>	<i>vd.number_of_connected_components()</i>	Returns the number of connected components of the Voronoi skeleton.
<i>Face_handle</i>	<i>vd.unbounded_face()</i>	Returns one of the unbounded faces of the Voronoi diagram. If no unbounded faces exist (this can happen if the number of sites is zero) the default constructed face handle is returned.

<i>Face_handle</i>	<i>vd.bounded_face()</i>	Returns one of the bounded faces of the Voronoi diagram. If no bounded faces exist the default constructed face handle is returned.
<i>Halfedge_handle</i>	<i>vd.unbounded_halfedge()</i>	Returns one of the unbounded halfedges of the Voronoi diagram. If no unbounded halfedges exist the default constructed halfedge handle is returned.
<i>Halfedge_handle</i>	<i>vd.bounded_halfedge()</i>	Returns one of the bounded halfedges of the Voronoi diagram. If no bounded halfedges exist the default constructed halfedge handle is returned.

Traversal of the Voronoi diagram

A Voronoi diagram can be seen as a container of faces, vertices and halfedges. Therefore the Voronoi diagram provides several iterators and circulators that allow to traverse it.

Iterators

The following iterators allow respectively to visit the faces (all or only the unbounded/bounded ones), edges, halfedges (all or only the unbounded/bounded ones) and vertices of the Voronoi diagram. These iterators are non-mutable, bidirectional and their value types are respectively *Face*, *Halfedge*, *Halfedge* and *Vertex*. All iterators are convertible to the corresponding handles and are invalidated by any change in the Voronoi diagram.

<i>Face_iterator</i>	<i>vd.faces_begin()</i>	Starts at an arbitrary Voronoi face.
<i>Face_iterator</i>	<i>vd.faces_end()</i>	Past-the-end iterator.
<i>Unbounded_faces_iterator</i>	<i>vd.unbounded_faces_begin()</i>	Starts at an arbitrary unbounded Voronoi face.
<i>Unbounded_faces_iterator</i>	<i>vd.unbounded_faces_end()</i>	Past-the-end iterator.
<i>Bounded_faces_iterator</i>	<i>vd.bounded_faces_begin()</i>	Starts at an arbitrary bounded Voronoi face.
<i>Bounded_faces_iterator</i>	<i>vd.bounded_faces_end()</i>	Past-the-end iterator.
<i>Edge_iterator</i>	<i>vd.edges_begin()</i>	Starts at an arbitrary Voronoi edge.
<i>Edge_iterator</i>	<i>vd.edges_end()</i>	Past-the-end iterator.
<i>Halfedge_iterator</i>	<i>vd.halfedges_begin()</i>	Starts at an arbitrary Voronoi halfedge.
<i>Halfedge_iterator</i>	<i>vd.halfedges_end()</i>	Past-the-end iterator.
<i>Unbounded_halfedges_iterator</i>	<i>vd.unbounded_halfedges_begin()</i>	Starts at an arbitrary unbounded Voronoi edge.
<i>Unbounded_halfedges_iterator</i>	<i>vd.unbounded_halfedges_end()</i>	Past-the-end iterator.
<i>Bounded_halfedges_iterator</i>	<i>vd.bounded_halfedges_begin()</i>	Starts at an arbitrary bounded Voronoi edge.
<i>Bounded_halfedges_iterator</i>	<i>vd.bounded_halfedges_end()</i>	Past-the-end iterator.

<i>Vertex_iterator</i>	<i>vd.vertices_begin()</i>	Starts at an arbitrary Voronoi vertex.
<i>Vertex_iterator</i>	<i>vd.vertices_end()</i>	Past-the-end iterator.

The following iterator provides access to the sites that define the Voronoi diagram. Its value type is *Site_2*. It is invalidated by any change in the Voronoi diagram.

<i>Site_iterator</i>	<i>vd.sites_begin()</i>	Starts at an arbitrary site.
<i>Site_iterator</i>	<i>vd.sites_end()</i>	Past-the-end iterator.

Circulators

The Voronoi diagram adaptor also provides circulators that allow to visit all halfedges whose target is a given vertex – this is the *Halfedge_around_vertex_circulator*, as well as all halfedges on the boundary of a Voronoi face – this is the *Ccb_halfedge_circulator*. These circulators are non-mutable and bidirectional. The operator *operator++* moves the former circulator counterclockwise around the vertex while the *operator--* moves clockwise. The latter circulator is moved by the operator *operator++* to the next halfedge on the boundary in the counterclockwise sense, while *operator--* moves clockwise. When the *Ccb_halfedge_circulator* is defined over an infinite Voronoi face *f*, then applying *operator++* to a circulator corresponding to a halfedge whose target is not finite moves to the next infinite (or semi-infinite) halfedge of *f* in the counterclockwise sense. Similarly, applying *operator++* to a circulator corresponding to a halfedge whose source is not finite, moves to the previous infinite (or semi-infinite) halfedge of *f* in the clockwise sense. The *Halfedge_around_vertex_circulator* circulator is invalidated by any modification in the faces adjacent to the vertex over which it is defined. The *Ccb_halfedge_circulator* is invalidated by any modification in the face over which it is defined.

<i>Ccb_halfedge_circulator</i>	<i>vd.ccb_halfedges(Face_handle f)</i>	Returns a circulator over the halfedges on the boundary of <i>f</i> . The circulator is initialized to an arbitrary halfedge on the boundary of the Voronoi face <i>f</i> .
--------------------------------	---	---

<i>Ccb_halfedge_circulator</i>	<i>vd.ccb_halfedges(Face_handle f, Halfedge_handle h)</i>	Returns a circulator over the halfedges on the boundary of <i>f</i> . The circulator is initialized with the halfedge <i>h</i> . <i>Precondition:</i> The halfedge <i>h</i> must lie on the boundary of <i>f</i> .
--------------------------------	--	---

<i>Halfedge_around_vertex_circulator</i>	<i>vd.incident_halfedges(Vertex_handle v)</i>	Returns a circulator over the halfedges whose target is the Voronoi vertex <i>v</i> . The circulator is initialized to an arbitrary halfedge incident to <i>v</i> .
--	--	---

<i>Halfedge_around_vertex_circulator</i>	<i>vd.incident_halfedges(Vertex_handle v, Halfedge_handle h)</i>	Returns a circulator over the halfedges whose target is the Voronoi vertex <i>v</i> . The circulator is initialized with the halfedge <i>h</i> . <i>Precondition:</i> The vertex <i>v</i> must be the target vertex of the halfedge <i>h</i> .
--	---	---

Insertion

Face_handle *vd.insert(Site_2 t)* Inserts the site *t* in the Voronoi diagram. A handle to the face corresponding to the Voronoi face of *t* in the Voronoi diagram is returned. If *t* has an empty Voronoi cell, the default constructed face handle is returned. This method is supported only if *Voronoi_traits::Has_inserter* is set to *CGAL::Tag_true*.

template<class Iterator>
size_type *vd.insert(Iterator first, Iterator beyond)*

Inserts, in the Voronoi diagram, the sites in the iterator range [*first*, *beyond*). The value type of *Iterator* must be *Site_2*. The number of sites in the iterator range is returned. This method is supported only if *Voronoi_traits::Has_inserter* is set to *CGAL::Tag_true*.

Queries

Locate_result *vd.locate(Point_2 p)* Performs point location for the query point *p*. In other words, the face, halfedge or vertex of the Voronoi diagram is found on which the point *p* lies. This method is supported only if *Voronoi_traits::Has_nearest_site_2* is set to *CGAL::Tag_true*.
Precondition: The Voronoi diagram must contain at least one face.

I/O

void *vd.file_output(std::ostream& os)* Writes the current state of the Voronoi diagram to the output stream *os*.
The following operator must be defined:
std::ostream& operator<<(std::ostream&, Delaunay_graph)

void *vd.file_input(std::istream& is)* Reads the current state of the Voronoi diagram from the input stream *is*.
The following operator must be defined:
std::istream& operator>>(std::istream&, Delaunay_graph)

std::ostream& *std::ostream& os << vd* Writes the current state of the Voronoi diagram to the output stream *os*.
The following operator must be defined:
std::ostream& operator<<(std::ostream&, Delaunay_graph)

std::istream& *std::istream& is >> vd* Reads the current state of the Voronoi diagram from the input stream *is*.
The following operator must be defined:
std::istream& operator>>(std::istream&, Delaunay_graph)

Validity check

bool *vd.is_valid()* Checks the validity of the dual Delaunay graph and the Voronoi diagram adaptor.

Miscellaneous

`void vd.clear()` Clears all contents of the Voronoi diagram.
`void vd.swap(other)` The Voronoi diagrams *other* and *vd* are swapped. *vd.swap(other)* should be preferred to *vd= other* or to *vd(other)* if *other* is deleted afterwards.

CGAL::Voronoi_diagram_2<DG,AT,AP>::Halfedge

Definition

The class *Halfedge* is the class provided by the *Voronoi_diagram_2<DG,AT,AP>* class for Voronoi halfedges. Below we present its interface.

Is Model for the Concepts

DefaultConstructible, *CopyConstructible*, *Assignable*, *EqualityComparable*, *LessThanComparable*

Types

<i>Halfedge::Vertex</i>		A type for the vertices of the Voronoi diagram.
<i>Halfedge::Face</i>		A type for the faces of the Voronoi diagram.
<i>Halfedge::Vertex_handle</i>		Handle for the vertices of the Voronoi diagram.
<i>Halfedge::Face_handle</i>		Handle for the faces of the Voronoi diagram.
<i>Halfedge::Halfedge_handle</i>		Handle for the halfedges of the Voronoi diagram.
<i>Halfedge::Ccb_halfedge_circulator</i>		A type for a bidirectional circulator over the halfedges of the boundary of a Voronoi face. The value type of the circulator is <i>CGAL::Voronoi_diagram_2<DG,AT,AP>::Halfedge</i> and is convertible to <i>Halfedge_handle</i> .
<i>Halfedge::Delaunay_graph</i>		A type for the Delaunay graph. It is a model of the <i>DelaunayGraph_2</i> concept.
<i>typedef Delaunay_graph::Edge</i>	<i>Delaunay_edge;</i>	A type for the dual edge in the Delaunay graph.
<i>typedef Delaunay_graph::Vertex_handle</i>	<i>Delaunay_vertex_handle;</i>	A type for vertex handles in the Delaunay graph.

Access Methods

<i>Halfedge_handle</i>	<i>e.twin()</i>	Returns the twin halfedge.
<i>Halfedge_handle</i>	<i>e.opposite()</i>	Same as <i>e.twin()</i> .
<i>Halfedge_handle</i>	<i>e.next()</i>	Returns the next halfedge in the counterclockwise sense around the boundary of the face that <i>e</i> is incident to.
<i>Halfedge_handle</i>	<i>e.previous()</i>	Returns the previous halfedge in the counterclockwise sense around the boundary of the adjacent face.

<i>Face_handle</i>	<i>e.face()</i>	Returns the face that <i>e</i> is incident to.
<i>Vertex_handle</i>	<i>e.source()</i>	Returns the source vertex of <i>e</i> . <i>Precondition:</i> The source vertex must exist, i.e., <i>has_source()</i> must return <i>true</i> .
<i>Vertex_handle</i>	<i>e.target()</i>	Returns the target vertex of <i>e</i> . <i>Precondition:</i> The target vertex must exist, i.e., <i>has_target()</i> must return <i>true</i> .
<i>Ccb_halfedge_circulator</i>	<i>e.ccb()</i>	Returns a bidirectional circulator to traverse the halfedges on the boundary of the Voronoi face containing <i>e</i> . The circulator is initialized to <i>e</i> . Applying <i>operator++</i> (resp. <i>operator--</i>) to this circulator returns the next halfedge on the boundary of the face containing <i>e</i> in the counterclockwise (resp. clockwise) sense.
<i>Delaunay_edge</i>	<i>e.dual()</i>	Returns the corresponding dual edge in the Delaunay graph.

In the four methods below we consider Voronoi halfedges to be “parallel” to the *x*-axis, oriented from left to right.

<i>Delaunay_vertex_handle</i>	<i>e.up()</i>	Returns a handle to the vertex in the Delaunay graph corresponding to the defining site above the Voronoi edge.
<i>Delaunay_vertex_handle</i>	<i>e.down()</i>	Returns a handle to the vertex in the Delaunay graph corresponding to the defining site below the Voronoi edge.
<i>Delaunay_vertex_handle</i>	<i>e.left()</i>	Returns a handle to the vertex in the Delaunay graph corresponding to the defining site to the left of the Voronoi edge. <i>Precondition:</i> <i>has_source()</i> must be <i>true</i> .
<i>Delaunay_vertex_handle</i>	<i>e.right()</i>	Returns a handle to the vertex in the Delaunay graph corresponding to the defining site to the right of the Voronoi edge. <i>Precondition:</i> <i>has_target()</i> must be <i>true</i> .

Predicate Methods

<i>bool e.has_source()</i>	Returns <i>true</i> iff the halfedge corresponds to a bisecting segment or a bisecting ray oriented appropriately so that its apex is its source.
<i>bool e.has_target()</i>	Returns <i>true</i> iff the halfedge corresponds to a bisecting segment or a bisecting ray oriented appropriately so that its apex is its target.
<i>bool e.is_unbounded()</i>	Returns <i>true</i> iff the source or the target of the halfedge does not exist, i.e., if either of <i>has_source()</i> or <i>has_target()</i> return <i>false</i> .
<i>bool e.is_bisector()</i>	Returns <i>true</i> iff the Voronoi edge is an entire bisector.
<i>bool e.is_segment()</i>	Returns <i>true</i> iff the Voronoi edge has both a source and a target Voronoi vertex.
<i>bool e.is_ray()</i>	Returns <i>true</i> iff the Voronoi edge has either a source or a target Voronoi vertex, but not both; in other words it is a bisecting ray.
<i>bool e.is_valid()</i>	Returns <i>true</i> if the following conditions are met: the halfedge is not a rejected edge with respect to the chosen adaptation policy; the twin edge of its twin edge is itself; its adjacent face is not a rejected face with respect to the chosen adaptation policy; its source and target vertices are valid (provided they exist, of course); the previous of its next halfedge is itself and the next of its previous halfedge is itself.

CGAL::Voronoi_diagram_2<DG,AT,AP>::Vertex

Definition

The class *Vertex* is the Voronoi vertex class provided by the class *Voronoi_diagram_2<DG,AT,AP>* class. Below we present its interface.

Is Model for the Concepts

DefaultConstructible, *CopyConstructible*, *Assignable*, *EqualityComparable*, *LessThanComparable*

Types

<i>Vertex:: Halfedge</i>	A type for the halfedges of the Voronoi diagram.
<i>Vertex:: Face</i>	A type for the faces of the Voronoi diagram.
<i>Vertex:: Vertex_handle</i>	Handle for the vertices of the Voronoi diagram.
<i>Vertex:: Face_handle</i>	Handle for the faces of the Voronoi diagram.
<i>Vertex:: Halfedge_handle</i>	Handle for the halfedges of the Voronoi diagram.
<i>Vertex:: Point_2</i>	A type for the point represented by the vertex.
<i>Vertex:: size_type</i>	A type for sizes.
<i>Vertex:: Halfedge_around_vertex_circulator</i>	A type for a bidirectional circulator that allows to traverse all incident halfedges, i.e., all halfedges that have the vertex as their target. The value type of the circulator is <i>CGAL::Voronoi_diagram_2<DG,AT,AP>::Halfedge</i> and is convertible to <i>Halfedge_handle</i> .
<i>Vertex:: Delaunay_graph</i>	A type for the Delaunay graph. It is a model of the <i>DelaunayGraph_2</i> concept.
<i>typedef Delaunay_graph::Face_handle Delaunay_face_handle;</i>	A type for the handle of the dual face.
<i>typedef Delaunay_graph::Vertex_handle Delaunay_vertex_handle;</i>	A type for the vertex handles in the Delaunay graph.

Access Methods

<i>Halfedge_handle</i>	<i>v.halfedge()</i>	Returns an incident halfedge that has <i>v</i> as its target.
<i>size_type</i>	<i>v.degree()</i>	Returns the in-degree of the vertex, i.e. the number of halfedges that have <i>v</i> as their target.
<i>Point_2</i>	<i>v.point()</i>	Returns the point represented by the vertex.
<i>Delaunay_face_handle</i>	<i>v.dual()</i>	Returns a handle to the corresponding dual face in the Delaunay graph.

Delaunay_vertex_handle *v.site(unsigned int i)* Returns a handle to the vertex in the Delaunay graph corresponding to the $(i + 1)$ -th generating site of the Voronoi vertex.

Precondition: *i* must be smaller or equal to 2.

Halfedge_around_vertex_circulator *v.incident_halfedges()* Returns a bidirectional circulator that allows the traversal of the halfedges that have *v* as their target. Applying *operator++* (resp. *operator--*) to this circulator returns the next incident halfedge in the counterclockwise (resp. clockwise) sense.

Predicate Methods

bool v.is_incident_edge(Halfedge_handle e) Returns *true* if the halfedge *e* is incident to *v*.
bool v.is_incident_face(Face_handle e) Returns *true* if the face *f* is incident to *v*.
bool v.is_valid() Returns *true* if the following conditions are met: the dual face is not an infinite face; all incident halfedges have the vertex as their target.

CGAL::Voronoi_diagram_2<DG,AT,AP>::Face

Definition

The class *Face* is the class provided by the *Voronoi_diagram_2<DG,AT,AP>* class for Voronoi faces. Below we present its interface.

Is Model for the Concepts

DefaultConstructible, *CopyConstructible*, *Assignable*, *EqualityComparable*, *LessThanComparable*

Types

<i>Face:: Vertex</i>	A type for the vertices of the Voronoi diagram.
<i>Face:: Halfedge</i>	A type for the halfedges of the Voronoi diagram.
<i>Face:: Vertex_handle</i>	Handle for the vertices of the Voronoi diagram.
<i>Face:: Face_handle</i>	Handle for the faces of the Voronoi diagram.
<i>Face:: Halfedge_handle</i>	Handle for the halfedges of the Voronoi diagram.
<i>Face:: Ccb_halfedge_circulator</i>	A type for a bidirectional circulator over the halfedges on the boundary of the face. The value type of the circulator is <i>CGAL::Voronoi_diagram_2<DG,AT,AP>::Halfedge</i> , and is convertible to <i>Halfedge_handle</i> .
<i>Face:: Delaunay_graph</i>	A type for the Delaunay graph. It is a model of the <i>DelaunayGraph_2</i> concept.
<i>typedef Delaunay_graph::Vertex_handle</i>	<i>Delaunay_vertex_handle</i> ; A type for the handle of the dual vertex.

Access Methods

<i>Halfedge_handle</i>	<i>f.halfedge()</i>	Returns an incident halfedge on the boundary of <i>f</i> .
<i>Ccb_halfedge_circulator</i>	<i>f.ccb()</i>	Returns a bidirectional circulator for traversing the halfedges on the boundary of <i>f</i> . The halfedges are traversed in counterclockwise order.
<i>Delaunay_vertex_handle</i>	<i>f.dual()</i>	Returns a handle to the corresponding dual vertex in the Delaunay graph.

Predicate Methods

<i>bool</i>	<i>f.is_unbounded()</i>	Returns <i>true</i> iff the face is an unbounded face in the Voronoi diagram.
<i>bool</i>	<i>f.is_halfedge_on_ccb(Halfedge e)</i>	Returns <i>true</i> iff <i>e</i> is a halfedge of the boundary of <i>f</i> .

bool *f.is_valid()*

Returns *true* iff the following conditions are met: the face is not rejected by the chosen adaptation policy; all its adjacent halfedges do not have zero length; all its adjacent halfedges return the face as their adjacent face.

DelaunayGraph_2

DelaunayGraph_2

Definition

The concept *DelaunayGraph_2* defines the requirements for the first template parameter of the *Voronoi_diagram_2*<DG,AT,AP> class. The *DelaunayGraph_2* concept essentially defines the requirements that a class representing a Delaunay graph must obey so that the Voronoi diagram adaptor can adapt it.

Refines

DefaultConstructible, *CopyConstructible*, *Assignable*

Types

<i>DelaunayGraph_2:: size_type</i>	A type for sizes.
<i>DelaunayGraph_2:: Geom_traits</i>	A type for the geometric traits associated with the Delaunay graph.
<i>DelaunayGraph_2:: Triangulation_data_structure</i>	A type for the underlying triangulation data structure. It must be a model of the concept <i>TriangulationDataStructure_2</i> .
<i>DelaunayGraph_2:: Vertex</i>	A type for the vertices of the Delaunay graph.
<i>DelaunayGraph_2:: Face</i>	A type for the faces of the Delaunay graph.
<i>typedef std::pair<Face_handle,int> Edge;</i>	The type of the edges of the Delaunay graph.
<i>DelaunayGraph_2:: Vertex_handle</i>	Handle to the vertices of the Delaunay graph.
<i>DelaunayGraph_2:: Face_handle</i>	Handle to the faces of the Delaunay graph.

The following iterators and circulators must be defined. All iterators and circulators must be assignable and convertible to their corresponding handles.

<i>DelaunayGraph_2:: All_edges_iterator</i>	A type for an iterator over all edges of the Delaunay graph. Its value type must be <i>Edge</i> .
<i>DelaunayGraph_2:: Finite_edges_iterator</i>	A type for an iterator over the finite edges of the Delaunay graph. Its value type must be <i>Edge</i> .
<i>DelaunayGraph_2:: All_faces_iterator</i>	A type for an iterator over all faces of the Delaunay graph. Its value type must be <i>Face</i> .
<i>DelaunayGraph_2:: Finite_faces_iterator</i>	A type for an iterator over the finite faces of the Delaunay graph. Its value type must be <i>Face</i> .
<i>DelaunayGraph_2:: All_vertices_iterator</i>	A type for an iterator over all vertices of the Delaunay graph. Its value type must be <i>Vertex</i> .
<i>DelaunayGraph_2:: Finite_vertices_iterator</i>	A type for an iterator over the finite vertices of the Delaunay graph. Its value type must be <i>Vertex</i> .
<i>DelaunayGraph_2:: Face_circulator</i>	A type for a circulator over the adjacent faces of a vertex of the Delaunay graph. Its value type must be <i>Face</i> .
<i>DelaunayGraph_2:: Vertex_circulator</i>	A type for a circulator over the adjacent vertices of a vertex of the Delaunay graph. Its value type must be <i>Vertex</i> .
<i>DelaunayGraph_2:: Edge_circulator</i>	A type for a circulator over the adjacent edges of a vertex of the Delaunay graph. Its value type must be <i>Edge</i> .

Creation

In addition to the default and copy constructors, as well as the assignment operator, the following constructors are required.

<i>DelaunayGraph_2</i> <i>dg</i> (<i>Geom_traits</i> <i>gt</i>);	Constructor that takes an instance of the geometric traits.
<i>template<class It></i> <i>DelaunayGraph_2</i> <i>dg</i> (<i>It</i> <i>first</i> , <i>It</i> <i>beyond</i>);	Constructor that takes an iterator range. The value type of the iterator must be the type of the sites of the Delaunay graph.
<i>template<class It></i> <i>DelaunayGraph_2</i> <i>dg</i> (<i>It</i> <i>first</i> , <i>It</i> <i>beyond</i> , <i>Geom_traits</i> <i>gt</i>);	Constructor that takes an iterator range and an instance of the geometric traits. The value type of the iterator must be the type of the sites of the Delaunay graph.

Access methods

<i>Triangulation_data_structure</i>	<i>dg.tds()</i>	Returns a reference to the underlying triangulation data structure.
<i>Geom_traits</i>	<i>dg.geom_traits()</i>	Returns a reference to the geometric traits object.
<i>Vertex_handle</i>	<i>dg.infinite_vertex()</i>	Returns a handle to the infinite vertex.
<i>Vertex_handle</i>	<i>dg.finite_vertex()</i>	Returns a handle to a finite vertex, provided there exists one.
<i>Face_handle</i>	<i>dg.infinite_face()</i>	Returns a handle to a face incident to the infinite vertex.
<i>int</i>	<i>dg.dimension()</i>	Returns the dimension of the Delaunay graph.
<i>size_type</i>	<i>dg.number_of_vertices()</i>	Returns the number of finite vertices.
<i>size_type</i>	<i>dg.number_of_faces()</i>	Returns the number of faces (both finite and infinite).

Traversal of the Delaunay graph

A model of the *DelaunayGraph_2* concept must provide several iterators and circulators that allow to traverse it (completely or partially). All iterators and circulators must be convertible to the corresponding handles.

Face, Edge and Vertex Iterators

The following iterators must allow, respectively, to visit finite faces, finite edges and finite vertices of the Delaunay graph. These iterators must be non-mutable, bidirectional and their value types are respectively *Face*, *Edge* and *Vertex*.

<i>Finite_vertices_iterator</i>	<i>dg.finite_vertices_begin()</i>	Starts at an arbitrary finite vertex.
<i>Finite_vertices_iterator</i>	<i>dg.finite_vertices_end()</i>	Past-the-end iterator.
<i>Finite_edges_iterator</i>	<i>dg.finite_edges_begin()</i>	Starts at an arbitrary finite edge.
<i>Finite_edges_iterator</i>	<i>dg.finite_edges_end()</i>	Past-the-end iterator.
<i>Finite_faces_iterator</i>	<i>dg.finite_faces_begin()</i>	Starts at an arbitrary finite face.

<i>Finite_faces_iterator</i>	<i>dg.finite_faces_end()</i>	Past-the-end iterator.
------------------------------	------------------------------	------------------------

The following iterators must allow, respectively, to visit all (both finite and infinite) faces, edges and vertices of the Delaunay graph. These iterators are non-mutable, bidirectional and their value types are respectively *Face*, *Edge* and *Vertex*.

<i>All_vertices_iterator</i>	<i>dg.all_vertices_begin()</i>	Starts at an arbitrary vertex.
<i>All_vertices_iterator</i>	<i>dg.all_vertices_end()</i>	Past-the-end iterator.
<i>All_edges_iterator</i>	<i>dg.all_edges_begin()</i>	Starts at an arbitrary edge.
<i>All_edges_iterator</i>	<i>dg.all_edges_end()</i>	Past-the-end iterator.
<i>All_faces_iterator</i>	<i>dg.all_faces_begin()</i>	Starts at an arbitrary face.
<i>All_faces_iterator</i>	<i>dg.all_faces_end()</i>	Past-the-end iterator.

Face, Edge and Vertex Circulators

A model of the *DelaunayGraph_2* concept must also provide circulators that allow to visit, respectively, all faces or edges incident to a given vertex or all vertices adjacent to a given vertex. These circulators are non-mutable and bidirectional. The operator *operator++* must move the circulator counterclockwise around the vertex while the *operator--* must move the circulator clockwise.

<i>Face_circulator</i>	<i>dg.incident_faces(Vertex_handle v)</i>	Starts at an arbitrary face incident to <i>v</i> .
<i>Face_circulator</i>	<i>dg.incident_faces(Vertex_handle v, Face_handle f)</i>	Starts at face <i>f</i> . <i>Precondition:</i> Face <i>f</i> must be incident to vertex <i>v</i> .
<i>Edge_circulator</i>	<i>dg.incident_edges(Vertex_handle v)</i>	Starts at an arbitrary edge incident to <i>v</i> .
<i>Edge_circulator</i>	<i>dg.incident_edges(Vertex_handle v, Face_handle f)</i>	Starts at the first edge of <i>f</i> incident to <i>v</i> , in counterclockwise order around <i>v</i> . <i>Precondition:</i> Face <i>f</i> must be incident to vertex <i>v</i> .
<i>Vertex_circulator</i>	<i>dg.incident_vertices(Vertex_handle v)</i>	Starts at an arbitrary vertex incident to <i>v</i> .
<i>Vertex_circulator</i>	<i>dg.incident_vertices(Vertex_handle v, Face_handle f)</i>	Starts at the first vertex of <i>f</i> adjacent to <i>v</i> in counterclockwise order around <i>v</i> . <i>Precondition:</i> Face <i>f</i> must be incident to vertex <i>v</i> .

Predicates

A model of the *DelaunayGraph_2* concept must provide methods to test the finite or infinite character of any feature.

<i>bool</i>	<i>dg.is_infinite(Vertex_handle v)</i>	<i>true</i> , iff <i>v</i> is the <i>infinite_vertex</i> .
<i>bool</i>	<i>dg.is_infinite(Face_handle f)</i>	<i>true</i> , iff face <i>f</i> is infinite.
<i>bool</i>	<i>dg.is_infinite(Face_handle f, int i)</i>	<i>true</i> , iff edge (<i>f</i> , <i>i</i>) is infinite.
<i>bool</i>	<i>dg.is_infinite(Edge e)</i>	<i>true</i> , iff edge <i>e</i> is infinite.
<i>bool</i>	<i>dg.is_infinite(Edge_circulator ec)</i>	<i>true</i> , iff edge <i>*ec</i> is infinite.

Validity check

<i>bool</i>	<i>dg.is_valid(bool verbose = false)</i>	Checks the validity of the Delaunay graph. If <i>verbose</i> is <i>true</i> a short message is sent to <i>std::cerr</i> .
-------------	---	---

Miscellaneous

<i>void</i>	<i>dg.clear()</i>	Clears all contents of the Delaunay graph.
<i>void</i>	<i>dg.swap(other)</i>	The Delaunay graphs <i>other</i> and <i>dg</i> are swapped. <i>dg.swap(other)</i> should be preferred to <i>dg= other</i> or to <i>dg(other)</i> if <i>other</i> is deleted afterwards.

Has Models

CGAL::Delaunay_triangulation_2<Traits,Tds>
CGAL::Regular_triangulation_2<Traits,Tds>

AdaptationTraits_2

Definition

The concept *AdaptationTraits_2* defines the functors required for accessing geometric information in the Delaunay graph that is needed by the *Voronoi_diagram_2<DG,AT,AP>* class. It optionally defines a functor for performing nearest site queries. A tag is provided for determining whether this functor is defined or not.

Refines

DefaultConstructible, *CopyConstructible*, *Assignable*

Types

<i>AdaptationTraits_2:: Point_2</i>	A type for a point.	
<i>AdaptationTraits_2:: Site_2</i>	A type for the sites of the Voronoi diagram.	
<i>AdaptationTraits_2:: Delaunay_graph</i>	A type for the triangulated Delaunay graph. The type <i>Delaunay_graph</i> must be a model of the <i>DelaunayGraph_2</i> concept.	
<i>typedef Delaunay_graph::Edge</i>	<i>Delaunay_edge;</i>	The type of the edges of the Delaunay graph
<i>typedef Delaunay_graph::Face_handle</i>	<i>Delaunay_face_handle;</i>	The type of the face handles of the Delaunay graph
<i>typedef Delaunay_graph::Vertex_handle</i>	<i>Delaunay_vertex_handle;</i>	The type of the vertex handles of the Delaunay graph.
<i>AdaptationTraits_2:: Access_site_2</i>	<p>A type for a functor that accesses the site associated with a vertex. The functor should be a model of the concepts <i>DefaultConstructible</i>, <i>CopyConstructible</i>, <i>Assignable</i> and <i>AdaptableFunctor</i> (with one argument). The functor must provide the following operator:</p> <p style="text-align: center;"><i>result_type operator()(Delaunay_vertex_handle v)</i></p> <p>where the result type <i>result_type</i> must be either <i>Site_2</i> or <i>const Site_2&</i>.</p>	
<i>AdaptationTraits_2:: Construct_Voronoi_point_2</i>	<p>A type for a functor that constructs the dual point of a (triangular) face in the Delaunay graph. This point is the Voronoi vertex of the three sites defining the face in the Delaunay graph. The functor must be a model of the concepts <i>DefaultConstructible</i>, <i>CopyConstructible</i>, <i>Assignable</i>, <i>AdaptableFunctor</i> (with one argument). It must provide the following operator:</p> <p style="text-align: center;"><i>Point_2 operator()(Delaunay_face_handle f)</i> .</p> <p>The face handle <i>f</i> must not correspond to an infinite face.</p>	
<i>AdaptationTraits_2:: Has_nearest_site_2</i>	<p>A tag for determining if the adaptation traits class provides a functor for performing nearest site queries. This tag is equal to either <i>CGAL::Tag_true</i> (a nearest site query functor is available) or <i>CGAL::Tag_false</i> (a nearest site query functor is not available).</p>	

AdaptationTraits_2::Nearest_site_2

A type for a functor that performs nearest site queries. Semantically, the result of the query is either a face, edge or vertex of the Delaunay graph. It is a face if the query point has at least three closest sites; the returned face has closest sites as vertices. It is an edge if the query point is equidistant to exactly two vertices of the Delaunay graph, which are the source and target vertices of the edge. In all other cases, the search result is a vertex, namely, the unique vertex of the Delaunay graph closest to the query point. The functor must be a model of the concepts *DefaultConstructible*, *CopyConstructible*, *Assignable*, *AdaptableFunctor* (with two arguments). It must provide the following operator:

result_type operator()(Delaunay_graph dg, Point_2 p)
where the result type *result_type* is *boost::variant< Delaunay_vertex_handle, Delaunay_edge, Delaunay_face_handle>*.

This type is required only if *Has_nearest_site_2* is equal to *CGAL::Tag_true*.

Access to objects

<i>Access_site_2</i>	<i>at.access_site_2_object()</i>
<i>Construct_Voronoi_point_2</i>	<i>at.construct_Voronoi_point_2_object()</i>
<i>Nearest_site_2</i>	<i>at.nearest_site_2_object()</i>

This method is required only if *Has_nearest_site_2* is equal to *CGAL::Tag_true*.

Has Models

AdaptationPolicy_2

Definition

The concept *AdaptationPolicy_2* defines the requirements on the predicate functors that determine whether a feature of the triangulated Delaunay graph should be rejected or not. It also provides a functor for inserting sites in the Delaunay graph. The last functor is optional and a tag determines whether it is provided or not. Note that while the first two functors do not modify the Delaunay graph they take as an argument, the last ones does.

Refines

DefaultConstructible, *CopyConstructible*, *Assignable*

Types

<i>AdaptationPolicy_2:: Site_2</i>	A type for the sites of the Voronoi diagram.
<i>AdaptationPolicy_2:: Delaunay_graph</i>	A type for the triangulated Delaunay graph. The type <i>Delaunay_graph</i> must be a model of the <i>DelaunayGraph_2</i> concept.
<i>typedef Delaunay_graph::Vertex_handle</i>	<i>Delaunay_vertex_handle;</i>
<i>typedef Delaunay_graph::Face_handle</i>	<i>Delaunay_face_handle;</i>
<i>typedef Delaunay_graph::Edge</i>	<i>Delaunay_edge;</i>
<i>typedef Delaunay_graph::All_edges_iterator</i>	<i>All_Delaunay_edges_iterator;</i>
<i>typedef Delaunay_graph::Finite_edges_iterator</i>	<i>Finite_Delaunay_edges_iterator;</i>
<i>typedef Delaunay_graph::Edge_circulator</i>	<i>Delaunay_edge_circulator;</i>
<i>AdaptationPolicy_2:: Edge_rejector</i>	<p>A type for the predicate functor that is responsible for rejecting an edge of the Delaunay graph (or equivalently rejecting its dual edge in the Voronoi diagram). It must be model of the concepts <i>DefaultConstructible</i>, <i>CopyConstructible</i>, <i>Assignable</i>, and <i>AdaptableFunctor</i> (with two arguments). It must provide the following operators:</p> <pre> bool operator()(Delaunay_graph dg, Delaunay_edge e) bool operator()(Delaunay_graph dg, Delaunay_face_handle f, int i) bool operator()(Delaunay_graph dg, Delaunay_edge_circulator ec) bool operator()(Delaunay_graph dg, All_Delaunay_edges_iterator eit) bool operator()(Delaunay_graph dg, Finite_Delaunay_edges_iterator eit) </pre> <p>The functor returns <i>true</i> iff the edge is rejected.</p>
<i>AdaptationPolicy_2:: Face_rejector</i>	<p>A type for the predicate functor that is responsible for rejecting a vertex of the Delaunay graph (or equivalently its dual face in the Voronoi diagram – hence the name of the functor). It must be model of the concepts <i>DefaultConstructible</i>, <i>CopyConstructible</i>, <i>Assignable</i>, <i>AdaptableFunctor</i> (with two arguments). It must provide the following operator:</p> <pre> bool operator()(Delaunay_graph dg, Delaunay_vertex_handle v) </pre> <p>The functor returns <i>true</i> iff the face is rejected.</p>
<i>AdaptationPolicy_2:: Has_inserter</i>	A tag for determining if the adaptation policy class provides a functor for inserting sites in the Delaunay graph. This tag is equal to either <i>CGAL::Tag_true</i> (a site inserter functor is available) or <i>CGAL::Tag_false</i> (a site inserter functor is not available).

CGAL::Apollonius_graph_adaptation_traits_2<AG2>

Definition

The class *Apollonius_graph_adaptation_traits_2*<AG2> provides a model for the *AdaptationTraits_2* concept. The template parameter of the *Apollonius_graph_adaptation_traits_2*<AG2> class must be a model of the *DelaunayGraph_2* concept, and in particular it has the semantics of a (triangulated) 2D Apollonius graph.

CGAL::Identity_policy_2<DG,AT>

Definition

The class *Identity_policy_2<DG,AT>* provides a model for the *AdaptationPolicy_2* concept. The first template parameter of the *Identity_policy_2<DG,AT>* class must be a model of the *DelaunayGraph_2* concept, whereas as the second template parameter must be a model of the *AdaptationTraits_2* concept. This policy rejects no edge and no face of the Delaunay graph, thus giving a Voronoi diagram which is the true dual of the triangulation Delaunay graph. The Voronoi diagram created with this adaptation policy may have degenerate features, such as Voronoi edges of zero length, or Voronoi faces of zero area. This policy assumes that the Delaunay graph, that is adapted, allows for site insertions through an *insert* method that takes as argument an object of type *AT::Site_2*. The site inserter functor provided by this policy uses the aforementioned *insert* method.

```
#include <CGAL/Identity_policy_2.h>

This package implements Shewchuk's algorithm [[She00](#)] to construct conforming triangulations and 2D meshes. Conforming triangulations will be described in Section [45.1](#) and meshes in Section [45.2](#).

45.1 Conforming Triangulations

45.1.1 Definitions

A triangulation is a *Delaunay triangulation* if the circumscribing circle of any facet of the triangulation contains no vertex in its interior. A *constrained Delaunay triangulation* is a constrained triangulation which is as much Delaunay as possible. The circumscribing circle of any facet of a constrained Delaunay triangulation contains in its interior no data point *visible* from the facet.

An edge is said to be a *Delaunay edge* if it is inscribed in an empty circle (containing no data point in its interior). This edge is said to be a *Gabriel edge* if its diametrical circle is empty.

A constrained Delaunay triangulation is said to be a *conforming Delaunay triangulation* if every constrained edge is a Delaunay edge. Because any edge in a constrained Delaunay triangulation is either a Delaunay edge or a constrained edge, a conforming Delaunay triangulation is in fact a Delaunay triangulation. The only difference is that some of the edges are marked as constrained edges.

A constrained Delaunay triangulation is said to be a *conforming Gabriel triangulation* if every constrained edge is a Gabriel edge. The Gabriel property is stronger than the Delaunay property and each Gabriel edge is a Delaunay edge. Conforming Gabriel triangulations are thus also conforming Delaunay triangulations.

Any constrained Delaunay triangulation can be refined into a conforming Delaunay triangulation or into a conforming Gabriel triangulation by adding vertices, called *Steiner vertices*, on constrained edges until they are decomposed into subconstraints small enough to be Delaunay or Gabriel edges.

45.1.2 Building Conforming Triangulations

Constrained Delaunay triangulations can be refined into conforming triangulations by the two following global functions:

```
template<class CDT> void make_conforming_Delaunay_2 (CDT& t) and
template<class CDT> void make_conforming_Gabriel_2 (CDT& t).
```

In both cases, the template parameter *CDT* must be instantiated by a constrained Delaunay triangulation class. Such a class must be a model of the concept *ConstrainedDelaunayTriangulation_2*.

The geometric traits of the constrained Delaunay triangulation used to instantiate the parameter *CDT* has to be a model of the concept *ConformingDelaunayTriangulationTraits_2*.

The constrained Delaunay triangulation *t* is passed by reference and is refined into a conforming Delaunay triangulation or into a conforming Gabriel triangulation by adding vertices. The user is advised to make a copy of the input triangulation in the case where the original triangulation has to be preserved for other computations.

The algorithm used by *make_conforming_Delaunay_2* and *make_conforming_Gabriel_2* builds internal data structures that would be computed twice if the two functions are called consecutively on the same triangulation. In order to avoid these data to be constructed twice, the advanced user can use the class *Triangulation_conformer_2<CDT>* to refine a constrained Delaunay triangulation into a conforming Delaunay triangulation and then into a conforming Gabriel triangulation. For additional control of the refinement algorithm, this class also provides separate functions to insert one Steiner point at a time.

45.1.3 Example: Making a Triangulation Conforming Delaunay and Then Conforming Gabriel

This example inserts several segments into a constrained Delaunay triangulation, makes it conforming Delaunay, and then conforming Gabriel. At each step, the number of vertices of the triangulation is printed.

```
#include <CGAL/Exact_predicates_inexact_constructions_kernel.h>
#include <CGAL/Constrained_Delaunay_triangulation_2.h>
#include <CGAL/Triangulation_conformer_2.h>

#include <iostream>
```

```

typedef CGAL::Exact_predicates_inexact_constructions_kernel K;
typedef CGAL::Constrained_Delaunay_triangulation_2<K> CDT;
typedef CDT::Point Point;
typedef CDT::Vertex_handle Vertex_handle;

int main()
{
    CDT cdt;

    // construct a constrained triangulation
    Vertex_handle
        va = cdt.insert(Point( 5., 5.)),
        vb = cdt.insert(Point(-5., 5.)),
        vc = cdt.insert(Point( 4., 3.)),
        vd = cdt.insert(Point( 5.,-5.)),
        ve = cdt.insert(Point( 6., 6.)),
        vf = cdt.insert(Point(-6., 6.)),
        vg = cdt.insert(Point(-6.,-6.)),
        vh = cdt.insert(Point( 6.,-6.));

    cdt.insert_constraint(va,vb);
    cdt.insert_constraint(vb,vc);
    cdt.insert_constraint(vc,vd);
    cdt.insert_constraint(vd,va);
    cdt.insert_constraint(ve,vf);
    cdt.insert_constraint(vf,vg);
    cdt.insert_constraint(vg,vh);
    cdt.insert_constraint(vh,ve);

    std::cout << "Number of vertices before: "
                << cdt.number_of_vertices() << std::endl;

    // make it conforming Delaunay
    CGAL::make_conforming_Delaunay_2(cdt);

    std::cout << "Number of vertices after make_conforming_Delaunay_2: "
                << cdt.number_of_vertices() << std::endl;

    // then make it conforming Gabriel
    CGAL::make_conforming_Gabriel_2(cdt);

    std::cout << "Number of vertices after make_conforming_Gabriel_2: "
                << cdt.number_of_vertices() << std::endl;
}

```

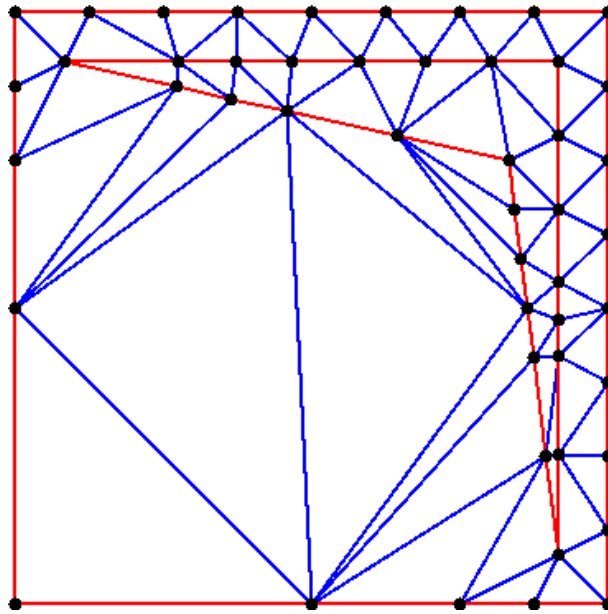

Figure 45.3: The corresponding conforming Gabriel triangulation.

45.2 Meshes

45.2.1 Definitions

A mesh is a partition of a given region into simplices whose shapes and sizes satisfy several criteria.

The domain is the region that the user wants to mesh. It has to be a bounded region of the plane. The domain is defined by a *planar straight line graph*, PSLG for short, which is a set of segments such that two segments in the set are either disjoint or share an endpoint. The segments of the PSLG are constraints that will be represented by a union of edges in the mesh. The PSLG can also contain isolated points that will appear as vertices of the mesh.

The segments of the PSLG are either segments of the boundary or internal constraints. The segments of the PSLG have to cover the boundary of the domain.

The PSLG divides the plane into several connected components. By default, the domain is the union of the bounded connected components. The user can override this default by providing a set of seed points. Either seed points mark components to be meshed or they mark components not to be meshed (holes).

See figures 45.4 and 45.5 for an example of a domain defined without using seed points, and a possible mesh of it. See figure 45.6 for another domain defined with the same PSLG and two seed points used to define holes. In the corresponding mesh (figure 45.7), these two holes are triangulated but not meshed.

45.2.2 Shape and Size Criteria

The shape criterion for triangles is a lower bound B on the ratio between the circumradius and the shortest edge length. Such a bound implies a lower bound of $\arcsin \frac{1}{2B}$ on the minimum angle of the triangle and an upper

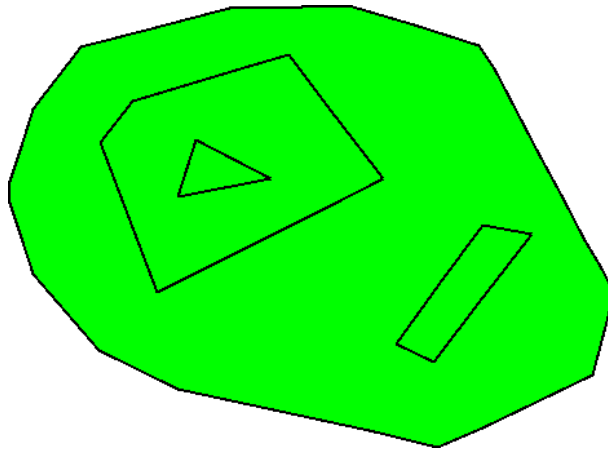

Figure 45.4: A domain defined without seed points.

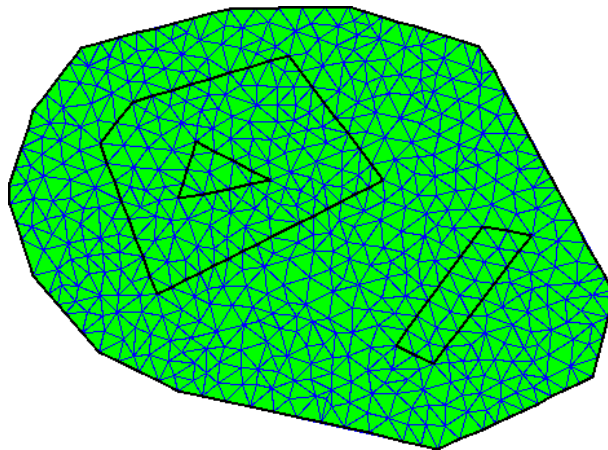

Figure 45.5: A mesh of the domain defined without seed points.

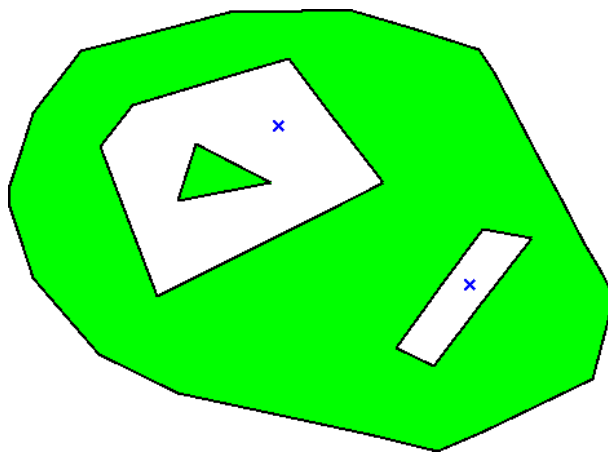

Figure 45.6: A domain with two seeds points defining holes.

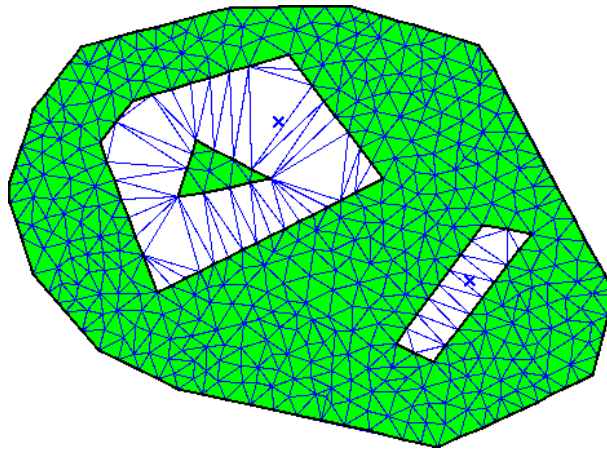

Figure 45.7: A mesh of the domain with two seeds defining holes.

bound of $\pi - 2 * \arcsin \frac{1}{2B}$ on the maximum angle. Unfortunately, the termination of the algorithm is guaranteed only if $B \geq \sqrt{2}$, which corresponds to a lower bound of 20.7 degrees over the angles.

The size criterion can be any criterion that tends to prefer small triangles. For example, the size criterion can be an upper bound on the length of longest edge of triangles, or an upper bound on the radius of the circumcircle. The size bound can vary over the domain. For example, the size criterion could impose a small size for the triangles intersecting a given line.

Both types of criteria are defined in an object *criteria* passed as parameter of the meshing functions.

45.2.3 The Meshing Algorithm

The input to a meshing problem is a PSLG and a set of seeds describing the domain to be meshed, and a set of size and shape criteria. The algorithm implemented in this package starts with a constrained Delaunay triangulation of the input PSLG and produces a mesh using the Delaunay refinement method. This method inserts new vertices to the triangulation, as far as possible from other vertices, and stops when the criteria are satisfied.

If all angles between incident segments of the input PSLG are greater than 60 degrees and if the bound on the circumradius/edge ratio is greater than $\sqrt{2}$, the algorithm is guaranteed to terminate with a mesh satisfying the size and shape criteria.

If some input angles are smaller than 60 degrees, the algorithm will end up with a mesh in which some triangles violate the criteria near small input angles. This is unavoidable since small angles formed by input segments cannot be suppressed. Furthermore, it has been shown ([She00]), that some domains with small input angles cannot be meshed with angles even smaller than the small input angles. Note that if the domain is a polygonal region, the resulting mesh will satisfy size and shape criteria except for the small input angles. In addition, the algorithm may succeed in producing meshes with a lower angle bound greater than 20.7 degrees, but there is no such guarantee.

45.2.4 Building Meshes

Meshes are obtained from constrained Delaunay triangulations by calling the global function `template<class CDT, class Criteria> void refine_Delaunay_mesh_2 (CDT &t, typename CDT::Geom_traits gt)`. The template parameter `CDT` must be instantiated by a constrained Delaunay triangulation class, which is a model of the concept `ConstrainedDelaunayTriangulation_2`. In order to override the domain, a version of this function has two more arguments that define a sequence of seed points.

The geometric traits class of `CDT` has to be a model of the concept `DelaunayMeshTraits_2`. This concept refines the concept `ConformingDelaunayTriangulationTraits_2` adding the geometric predicates and constructors. The template parameter `Criteria` must be a model of `MeshingCriteria_2`. This concept defines criteria that the triangles have to satisfy. CGAL provides two models for this concept:

- `Delaunay_mesh_criteria_2<CDT>`, that defines a shape criterion that bounds the minimum angle of triangles,
- `Delaunay_mesh_size_criteria_2<CDT>`, that adds to the previous criterion a bound on the maximum edge length.

If the function `refine_Delaunay_mesh_2` is called several times on the same triangulation with different criteria, the algorithm rebuilds the internal data structure used for meshing at every call. In order to avoid rebuild the data structure at every call, the advanced user can use the class `Delaunay_mesher_2<CDT>`. This class provides also step by step functions. Those functions insert one vertex at a time.

Any object of type `Delaunay_mesher_2<CDT>` is constructed from a reference to a `CDT`, and has several member functions to define the domain to be meshed and to mesh the `CDT`. See the example given below and the reference manual for details. Note that the `CDT` should not be externally modified during the life time of the `Delaunay_mesher_2<CDT>` object.

Once the mesh is constructed, one can determine which faces of the triangulation are in the mesh domain using the `is_in_domain()` member function of the face type (see the concept `DelaunayMeshFaceBase_2`).

45.2.5 Example Using the Global Function

The following example inserts several segments into a constrained triangulation and then meshes it using the global function `refine_Delaunay_mesh_2`. The size and shape criteria are the default ones provided by the criteria class `Delaunay_mesh_criteria_2<K>`. No seeds are given, meaning that the mesh domain covers the whole plane except the unbounded component.

```
#include <CGAL/Exact_predicates_inexact_constructions_kernel.h>
#include <CGAL/Constrained_Delaunay_triangulation_2.h>
#include <CGAL/Delaunay_mesher_2.h>
#include <CGAL/Delaunay_mesh_face_base_2.h>
#include <CGAL/Delaunay_mesh_size_criteria_2.h>

#include <iostream>

typedef CGAL::Exact_predicates_inexact_constructions_kernel K;
typedef CGAL::Triangulation_vertex_base_2<K> Vb;
typedef CGAL::Delaunay_mesh_face_base_2<K> Fb;
typedef CGAL::Triangulation_data_structure_2<Vb, Fb> Tds;
typedef CGAL::Constrained_Delaunay_triangulation_2<K, Tds> CDT;
```

```

typedef CGAL::Delaunay_mesh_size_criteria_2<CDT> Criteria;

typedef CDT::Vertex_handle Vertex_handle;
typedef CDT::Point Point;

int main()
{
    CDT cdt;

    Vertex_handle va = cdt.insert(Point(-4,0));
    Vertex_handle vb = cdt.insert(Point(0,-1));
    Vertex_handle vc = cdt.insert(Point(4,0));
    Vertex_handle vd = cdt.insert(Point(0,1));
    cdt.insert(Point(2, 0.6));

    cdt.insert_constraint(va, vb);
    cdt.insert_constraint(vb, vc);
    cdt.insert_constraint(vc, vd);
    cdt.insert_constraint(vd, va);

    std::cout << "Number of vertices: " << cdt.number_of_vertices() <<
        std::endl;

    std::cout << "Meshing the triangulation..." << std::endl;
    CGAL::refine_Delaunay_mesh_2(cdt, Criteria(0.125, 0.5));

    std::cout << "Number of vertices: " << cdt.number_of_vertices() <<
        std::endl;
}

```

File: examples/Mesh_2/mesh_global.cpp

45.2.6 Example Using the Class `Delaunay_mesher_2<CDT>`

This example uses the class `Delaunay_mesher_2<CDT>` and calls the `refine_mesh()` member function twice, changing the size and shape criteria in between. In such a case, using twice the global function `refine_Delaunay_mesh_2` would be less efficient, because some internal structures needed by the algorithm would be built twice.

```

#include <CGAL/Exact_predicates_inexact_constructions_kernel.h>
#include <CGAL/Constrained_Delaunay_triangulation_2.h>
#include <CGAL/Delaunay_mesher_2.h>
#include <CGAL/Delaunay_mesh_face_base_2.h>
#include <CGAL/Delaunay_mesh_size_criteria_2.h>

#include <iostream>

typedef CGAL::Exact_predicates_inexact_constructions_kernel K;
typedef CGAL::Triangulation_vertex_base_2<K> Vb;
typedef CGAL::Delaunay_mesh_face_base_2<K> Fb;
typedef CGAL::Triangulation_data_structure_2<Vb, Fb> Tds;
typedef CGAL::Constrained_Delaunay_triangulation_2<K, Tds> CDT;
typedef CGAL::Delaunay_mesh_size_criteria_2<CDT> Criteria;

```

```

typedef CGAL::Delaunay_mesher_2<CDT, Criteria> Mesher;

typedef CDT::Vertex_handle Vertex_handle;
typedef CDT::Point Point;

int main()
{
    CDT cdt;

    Vertex_handle va = cdt.insert(Point(-4,0));
    Vertex_handle vb = cdt.insert(Point(0,-1));
    Vertex_handle vc = cdt.insert(Point(4,0));
    Vertex_handle vd = cdt.insert(Point(0,1));
    cdt.insert(Point(2, 0.6));

    cdt.insert_constraint(va, vb);
    cdt.insert_constraint(vb, vc);
    cdt.insert_constraint(vc, vd);
    cdt.insert_constraint(vd, va);

    std::cout << "Number of vertices: " << cdt.number_of_vertices() <<
        std::endl;

    std::cout << "Meshing the triangulation with default criterias..."
        << std::endl;

    Mesher mesher(cdt);
    mesher.refine_mesh();

    std::cout << "Number of vertices: " << cdt.number_of_vertices() <<
        std::endl;

    std::cout << "Meshing with new criterias..." << std::endl;
    // 0.125 is the default shape bound. It corresponds to about 20.6
    // degree.
    // 0.5 is the upper bound on the length of the longest edge.
    // See reference manual for Delaunay_mesh_size_traits_2<K>.
    mesher.set_criteria(Criteria(0.125, 0.5));
    mesher.refine_mesh();

    std::cout << "Number of vertices: " << cdt.number_of_vertices() <<
        std::endl;
}

```

File: examples/Mesh_2/mesh_class.cpp

45.2.7 Example Using Seeds

This example uses the global function *refine_Delaunay_mesh_2* but defines a domain by using one seed. The size and shape criteria are the default ones provided by the criteria class *Delaunay_mesh_criteria_2<K>*.

Once the mesh is constructed, the *is_in_domain()* member function of faces is used to count them.

```

#include <CGAL/Exact_predicates_inexact_constructions_kernel.h>
#include <CGAL/Constrained_Delaunay_triangulation_2.h>
#include <CGAL/Delaunay_mesher_2.h>
#include <CGAL/Delaunay_mesh_face_base_2.h>
#include <CGAL/Delaunay_mesh_size_criteria_2.h>

#include <iostream>

typedef CGAL::Exact_predicates_inexact_constructions_kernel K;
typedef CGAL::Triangulation_vertex_base_2<K> Vb;
typedef CGAL::Delaunay_mesh_face_base_2<K> Fb;
typedef CGAL::Triangulation_data_structure_2<Vb, Fb> Tds;
typedef CGAL::Constrained_Delaunay_triangulation_2<K, Tds> CDT;
typedef CGAL::Delaunay_mesh_size_criteria_2<CDT> Criteria;

typedef CDT::Vertex_handle Vertex_handle;
typedef CDT::Point Point;

int main()
{
    CDT cdt;
    Vertex_handle va = cdt.insert(Point(2,0));
    Vertex_handle vb = cdt.insert(Point(0,2));
    Vertex_handle vc = cdt.insert(Point(-2,0));
    Vertex_handle vd = cdt.insert(Point(0,-2));

    cdt.insert_constraint(va, vb);
    cdt.insert_constraint(vb, vc);
    cdt.insert_constraint(vc, vd);
    cdt.insert_constraint(vd, va);

    va = cdt.insert(Point(3,3));
    vb = cdt.insert(Point(-3,3));
    vc = cdt.insert(Point(-3,-3));
    vd = cdt.insert(Point(3,0-3));

    cdt.insert_constraint(va, vb);
    cdt.insert_constraint(vb, vc);
    cdt.insert_constraint(vc, vd);
    cdt.insert_constraint(vd, va);

    std::list<Point> list_of_seeds;

    list_of_seeds.push_back(Point(0, 0));

    std::cout << "Number of vertices: " << cdt.number_of_vertices() <<
        std::endl;

    std::cout << "Meshing the domain..." << std::endl;
    CGAL::refine_Delaunay_mesh_2(cdt, list_of_seeds.begin(),
        list_of_seeds.end(),
                                Criteria());

    std::cout << "Number of vertices: " << cdt.number_of_vertices() <<

```

```

    std::endl;
    std::cout << "Number of finite faces: " << cdt.number_of_faces() <<
        std::endl;
    int mesh_faces_counter = 0;
    for(CDT::Finite_faces_iterator fit = cdt.finite_faces_begin();
        fit != cdt.finite_faces_end(); ++fit)
    {
        if(fit->is_in_domain()) ++mesh_faces_counter;
    }
    std::cout << "Number of faces in the mesh domain: " <<
        mesh_faces_counter << std::endl;
}

```

ConformingDelaunayTriangulationTraits_2

Definition

The concept `ConformingDelaunayTriangulationTraits_2` refines the concept `ConstrainedDelaunayTriangulationTraits_2` by providing a numeric field type *FT*, a type *Vector_2* and several constructors on *Vector_2*, *Point_2*, and a predicate on angles. The field type has to be a model of the concept *SqrtFieldType*. This field type and the constructors are used by the conforming algorithm to compute Steiner points on constrained edges.

Refines

DelaunayTriangulationTraits_2

Types

ConformingDelaunayTriangulationTraits_2:: FT

The field type. It must be a model of *SqrtFieldType*, that is must be a number type supporting the operations $+$, $-$, $*$, $/$, and $\sqrt{\cdot}$.

ConformingDelaunayTriangulationTraits_2:: Vector_2

The vector type.

ConformingDelaunayTriangulationTraits_2:: Construct_vector_2

Constructor object. Must provide the operator *Vector_2 operator()(Point a, Point b)* that computes the vector $b - a$.

ConformingDelaunayTriangulationTraits_2:: Construct_scaled_vector_2

Constructor object. Must provide the operator *Vector_2 operator()(Vector_2 v, FT scale)* that computes the vector $scale \cdot v$.

ConformingDelaunayTriangulationTraits_2:: Construct_translated_point_2

Constructor object. Must provide the operator *Point_2 operator()(Point_2 p, Vector_2 v)* that computes the point $p + v$.

ConformingDelaunayTriangulationTraits_2:: Construct_midpoint_2

Constructor object. Must provide the operator *Point_2 operator()(Point_2 a, Point_2 b)* that computes the midpoint of the segment ab .

ConformingDelaunayTriangulationTraits_2:: Compute_squared_distance_2

Constructor object. Must provide the operator *FT operator()(Point_2 a, Point_2 b)* that computes the squared distance between *a* and *b*.

ConformingDelaunayTriangulationTraits_2:: Angle_2

Predicate object. Must provide the operator *CGAL::Angle operator()(Point_2 p, Point_2 q, Point_2 r)* that returns OB-TUSE, RIGHT or ACUTE depending on the angle formed by the three points *p*, *q*, *r* (*q* being the vertex of the angle).

Access to predicate and constructor objects

<i>Construct_vector_2</i>	<i>traits.construct_vector_2_object()</i>
<i>Construct_scaled_vector_2</i>	<i>traits.construct_scaled_vector_2_object()</i>
<i>Construct_translated_point_2</i>	<i>traits.construct_translated_point_2_object()</i>
<i>Constructor_midpoint_2</i>	<i>traits.construct_midpoint_2_object()</i>
<i>Compute_squared_distance_2</i>	<i>traits.compute_squared_distance_2_object()</i>
<i>Angle_2</i>	<i>traits.angle_2_object()</i>

Has Models

Any model of *Kernel* concept. In particular, all CGAL kernels.

DelaunayMeshFaceBase_2

Definition

The concept `DelaunayMeshFaceBase_2` refines the concept `TriangulationFaceBase_2`. It adds two functions giving access to a Boolean marker, that indicates if the face is in the meshing domain or not.

Refines

ConstrainedTriangulationFaceBase_2

Access Functions

bool *f.is_in_domain()* returns true if this face is in the domain to be refined.

void *f.set_in_domain(const bool b)*
sets if this face is in the domain.

Has Models

Delaunay_mesh_face_base_2<Traits, Fb>

DelaunayMeshTraits_2

Definition

The concept `DelaunayMeshTraits_2` refines the concept `ConformingDelaunayTriangulationTraits_2`. It provides a construction object `Construct_circumcenter_2`.

Refines

`ConformingDelaunayTriangulationTraits_2`

Types

`DelaunayMeshTraits_2::Construct_circumcenter_2`

Constructor object. Must provide an operator `Point_2 operator()(Point_2 p, Point_2 q, Point_2 r)`; that computes the center of the circle passing through the points p , q and r .
Precondition: p , q and r are not collinear.

Access to predicate and constructor objects

`Construct_circumcenter_2` `traits.construct_circumcenter_2_object()`

Has Models

Any model of the *Kernel* concept. In particular, all CGAL kernels.

CGAL::Delaunay_mesher_2<CDT, Criteria>

This class implements a 2D mesh generator.

```
#include <CGAL/Delaunay_mesher_2.h>
```

Parameters

The template parameter *CDT* should be a model of the concept *ConstrainedDelaunayTriangulation_2*, and type *CDT::Face* should be a model of the concept *MeshFaceBase_2*.

The geometric traits class of the instance of *CDT* has to be a model of the concept *DelaunayMeshTraits_2*.

The template parameter *Criteria* should be a model of the concept *MeshingCriteria_2*. This traits class defines the shape and size criteria for the triangles of the mesh. *Criteria::Face_handle* has to be the same as *CDT::Face_handle*.

Using this class

The constructor of the class *Delaunay_mesher_2<CDT, Criteria>* takes a reference to a *CDT* as an argument. A call to the refinement method *refine_mesh()* will refine the constrained Delaunay triangulation into a mesh satisfying the size and shape criteria specified in the traits class. Note that if, during the life time of the *Delaunay_mesher_2<CDT, Criteria>* object, the triangulation is externally modified, any further call to its member methods may crash. Consider constructing a new *Delaunay_mesher_2<CDT, Criteria>* object if the triangulation has been modified.

Meshing domain

The domain to be mesh is defined by the constrained edges and a set of seed points. The constrained edges divides the plane into several connected components. The mesh domain is either the union of the bounded connected components including at least one seed, or the union of the bounded connected components that do not contain any seed. Note that the unbounded component of the plane is never meshed.

Types

```
typedef CDT::Geom_traits
```

Geom_traits; the geometric traits class.

```
Delaunay_mesher_2<CDT, Criteria>:: Seeds_iterator
```

const iterator over defined seeds. Its value type is *Geom_traits::Point_2*.

Creation

```
Delaunay_mesher_2<CDT, Criteria> mesher( CDT& t, Criteria criteria = Criteria());
```

Create a new mesher, working on *t*, with meshing criteria *criteria*.

Seeds functions

The following functions are used to define seeds.

<i>void</i>	<i>mesher.clear_seeds()</i>	Sets seeds to the empty set. All finite connected components of the constrained triangulation will be refined.
-------------	-----------------------------	--

<i>template<class InputIterator></i>		
<i>void</i>	<i>mesher.set_seeds(InputIterator begin, InputIterator end, const bool mark=false)</i>	Sets seeds to the sequence <i>[begin, end]</i> . If <i>mark=true</i> , the mesh domain is the union of the bounded connected components including at least one seed. If <i>mark=false</i> , the domain is the union of the bounded components including no seed. Note that the unbounded component of the plane is never meshed. <i>Requirement:</i> The <i>value_type</i> of <i>begin</i> and <i>end</i> is <i>Geom_traits::Point_2</i> .

<i>Seeds_const_iterator</i>	<i>mesher.seeds_begin()</i>	Start of the seeds sequence.
<i>Seeds_const_iterator</i>	<i>mesher.seeds_end()</i>	Past the end of the seeds sequence.

Meshing methods

<i>void</i>	<i>mesher.refine_mesh()</i>	Refines the constrained Delaunay triangulation into a mesh satisfying the criteria defined by the traits.
-------------	-----------------------------	---

<i>Criteria</i>	<i>mesher.get_criteria()</i>	Returns a const reference to the criteria traits object.
-----------------	------------------------------	--

<i>void</i>	<i>mesher.set_criteria(Criteria criteria)</i>	
		Assigns <i>criteria</i> to the criteria traits object.

— *advanced* —

The function *set_criteria* scans all faces to recalculate the list of *bad faces*, that are faces not conforming to the meshing criteria. This function actually has an optional argument that permits to prevent this recalculation. The filling of the list of bad faces can then be done by a call to *set_bad_faces*.

<i>void</i>	<i>mesher.set_criteria(Criteria criteria, bool recalculate_bad_faces)</i>	
		Assigns <i>criteria</i> to the criteria traits object. If <i>recalculate_bad_faces</i> is <i>false</i> , the list of bad faces is let empty and the function <i>set_bad_faces</i> should be called before <i>refine_mesh</i> .

template <class InputIterator>

void *mesher.set_bad_faces(InputIterator begin, InputIterator end)*

This method permits to set the list of bad triangles directly, from the sequence [begin, end], so that the algorithm will not scan the whole set of triangles to find bad ones. To use if there is a non-naive way to find bad triangles.

Requirement: The *value_type* of *begin* and *end* is *Face_handle*.

|_____ *advanced* _____|

|_____ *advanced* _____|

Step by step operations

The *Delaunay_mesher_2*<*CDT*, *Criteria*> class allows, for debugging or demos, to play the meshing algorithm step by step, using the following methods.

void *mesher.init()*

This method must be called just before the first call to the following step by step refinement method, that is when all vertices and constrained edges have been inserted into the constrained Delaunay triangulation. It must be called again before any subsequent calls to the step by step refinement method if new vertices or constrained edges have been inserted since the last call.

bool *mesher.is_refinement_done()*

Tests if the step by step refinement algorithm is done. If it returns *true*, the following calls to *step_by_step_refine_mesh* will not insert any points, until some new constrained segments or points are inserted in the triangulation and *init* is called again.

bool *mesher.step_by_step_refine_mesh()*

Applies one step of the algorithm, by inserting one point, if the algorithm is not done. Returns *false* iff no point has been inserted because the algorithm is done.

|_____ *advanced* _____|

CGAL::Delaunay_mesh_criteria_2<CDT>

Definition

The class *Delaunay_mesh_criteria_2<CDT>* is a model for the *MeshingCriteria_2* concept. The shape criterion on triangles is given by a bound B such that for good triangles $\frac{r}{l} \leq B$ where l is the shortest edge length and r is the circumradius of the triangle. By default, $B = \sqrt{2}$, which is the best bound one can use with the guarantee that the refinement algorithm will terminate. The upper bound B is related to a lower bound α_{min} on the minimum angle in the triangle:

$$\sin \alpha_{min} = \frac{1}{2B}$$

so $B = \sqrt{2}$ corresponds to $\alpha_{min} \geq 20.7$ degrees.

```
#include <CGAL/Delaunay_mesh_criteria_2.h>
```

Is Model for the Concepts

MeshingCriteria_2

Creation

Delaunay_mesh_criteria_2<CDT> traits; Default constructor. $B = \sqrt{2}$.

Delaunay_mesh_criteria_2<CDT> traits(double $b = 0.125$);

Construct a traits class with bound $B = \sqrt{\frac{1}{4b}}$.

CGAL::Delaunay_mesh_face_base_2<Traits, Fb>

Definition

The class *Delaunay_mesh_face_base_2*<*Traits*, *Fb*> is a model for the concept *DelaunayMeshFaceBase_2*.

This class can be used directly or it can serve as a base to derive other classes with some additional attributes (a color for example) tuned to a specific application.

```
#include <CGAL/Delaunay_mesh_face_base_2.h>
```

Parameters

- The first parameter *Traits* is the geometric traits class. It must be the same as the one used for the Delaunay mesh.
- The second parameter *Fb* is the base class from which *Delaunay_mesh_face_base_2*<*Traits*, *Fb*> derives. It must be a model of the *TriangulationFaceBase_2* concept.

Inherits From

Fb

DelaunayMeshFaceBase_2

CGAL::Delaunay_mesh_size_criteria_2<CDT>

Definition

The class *Delaunay_mesh_size_criteria_2<CDT>* is a model for the *MeshingCriteria_2* concept. The shape criterion on triangles is given by a bound B such that for good triangles $\frac{l}{r} \leq B$ where l is the shortest edge length and r is the circumradius of the triangle. By default, $B = \sqrt{2}$, which is the best bound one can use with the guarantee that the refinement algorithm will terminate. The upper bound B is related to a lower bound α_{min} on the minimum angle in the triangle:

$$\sin \alpha_{min} = \frac{1}{2B}$$

so $B = \sqrt{2}$ corresponds to $\alpha_{min} \geq 20.7$ degrees.

This traits class defines also a size criteria: all segments of all triangles must be shorter than a bound S .

```
#include <CGAL/Delaunay_mesh_size_criteria_2.h>
```

Is Model for the Concepts

MeshingCriteria_2

Creation

Delaunay_mesh_size_criteria_2<CDT> traits; Default constructor. $B = \sqrt{2}$. No bound on size

Delaunay_mesh_size_criteria_2<CDT> traits(double $b = 0.125$, double $S = 0$);

Construct a traits class with bound $B = \sqrt{\frac{1}{4b}}$. If $S \neq 0$, the size bound is S . If $S = 0$, there is no bound on size.

CGAL::Mesh_2::Face_badness

```
#include <CGAL/Mesh_2/Face_badness.h>
```

```
enum Mesh_2::Face_badness { NOT_BAD, BAD, IMPERATIVELY_BAD};
```

CGAL::make_conforming_Delaunay_2

```
#include <CGAL/Triangulation_conformer_2.h>
```

```
template<class CDT>  
void make_conforming_Delaunay_2( CDT &t)
```

Refines the constrained Delaunay triangulation t into a conforming Delaunay triangulation. After a call to this function, all edges of t are Delaunay edges.

Requirement: The template parameter CDT should be a model of the concept *ConstrainedDelaunayTriangulation_2*. The geometric traits class of into the constrained Delaunay triangulation must be a model of *ConformingDelaunayTriangulationTraits_2*.

CGAL::make_conforming_Gabriel_2

```
#include <CGAL/Triangulation_conformer_2.h>
```

```
template<class CDT>  
void make_conforming_Gabriel_2( CDT &t)
```

Refines the constrained Delaunay triangulation t into a conforming Gabriel triangulation. After a call to this function, all constrained edges of t have the *Gabriel property*: the circle that has e as diameter does not contain any vertex from the triangulation.

Requirement: The template parameter CDT should be a model of the concept *ConstrainedDelaunayTriangulation_2*. The geometric traits class of the constrained Delaunay triangulation must be a model of *ConformingDelaunayTriangulationTraits_2*.

MeshingCriteria_2

Definition

The concept `MeshingCriteria_2` defines the meshing criteria to be used in the algorithm. It provides a predicate *Is_bad* that tests a triangle according to criteria. The return type of *Is_bad* is an enum *Mesh_2::Face_badness*.

The possible values of *Mesh_2::Face_badness* are *NOT_BAD*, *BAD* and *IMPERATIVELY_BAD*. If the predicate returns *BAD*, the triangle is marked as bad and the algorithm will try to destroy it. If the predicate returns *IMPERATIVELY_BAD*, the algorithm will destroy the triangle unconditionally during its execution.

The termination of the algorithm is guaranteed when criteria are shape criteria corresponding to a bound on smallest angles not less than 20.7 degrees (this corresponds to a radius-edge ratio bound not less than $\sqrt{2}$). Any size criteria that are satisfied by small enough tetrahedra can be added to the set of criteria without compromising the termination.

Note that, in the presence of input angles smaller than 60 degrees, some bad shaped triangles can appear in the finale mesh in the neighboring of small angles. To achieve termination and the respect of size criteria everywhere, the *Is_bad* predicate has to return *IMPERATIVELY_BAD* when size criteria are not satisfied, and *BAD* when shape criteria are not satisfied.

`MeshingCriteria_2` also provides a type *Quality* designed to code a quality measure for triangles. The type *Quality* must be *less-than comparable* as the meshing algorithm will order bad triangles by quality, to split those with smallest quality first. The predicate *Is_bad* computes the quality of the triangle as a by-product.

Types

<i>MeshingCriteria_2:: Face_handle</i>	Handle to a face of the triangulation.
<i>MeshingCriteria_2:: Quality</i>	Default constructible, copy constructible, assignable, and less-than comparable type.
<i>MeshingCriteria_2:: Is_bad</i>	Predicate object. Must provide two operators. The first operator <i>Mesh_2::Face_badness operator()(Face_handle fh, Quality& q)</i> returns <i>NOT_BAD</i> if it satisfies the desired criteria for mesh triangles, <i>BAD</i> if it does not, and <i>IMPERATIVELY_BAD</i> if it does not and should be refined unconditionally. In addition, this operator assigns to <i>q</i> a value measuring the quality of the triangle pointed by <i>fh</i> . The second operator <i>Mesh_2::Face_badness operator()(Quality q)</i> returns <i>NOT_BAD</i> if <i>q</i> is the quality of a good triangle, <i>BAD</i> if the <i>q</i> represents a poor quality, and <i>IMPERATIVELY_BAD</i> if <i>q</i> represents the quality of a bad triangle that should be refined unconditionally.

Access to predicate and constructor objects

Is_bad *traits.is_bad_object()*

Has Models

Delaunay_mesh_criteria_2<CDT>

Delaunay_mesh_size_criteria_2<CDT>

CGAL::refine_Delaunay_mesh_2

```
template<class CDT, class Criteria>
void refine_Delaunay_mesh_2( CDT &t, Criteria criteria = Criteria())
```

Refines the default domain defined by a constrained Delaunay triangulation without seeds into a mesh satisfying the criteria defined by the traits *criteria*. The domain of the mesh covers all the connected components of the plane defined by the constrained edges of *t*, except for the unbounded component.

Precondition: The template parameter *CDT* must be a model of the concept *ConstrainedDelaunayTriangulation_2*. The geometric traits class of the constrained Delaunay triangulation must be a model of *DelaunayMeshTraits_2*.

Requirement: The face of the constrained Delaunay triangulation must be a model of the concept *DelaunayMeshFaceBase_2*. *Criteria* must be a model of the concept *MeshingCriteria_2* and *CDT::Face_handle* must be the same as *Criteria::Face_handle*.

```
template <class CDT, class Criteria, class InputIterator>
void refine_Delaunay_mesh_2( CDT& t,
                             InputIterator begin,
                             InputIterator end,
                             Criteria criteria = Criteria(),
                             bool mark = false)
```

Refines the default domain defined by a constrained Delaunay triangulation into a mesh satisfying the criteria defined by the traits *criteria*. The sequence *[begin, end]* gives a set of seeds points, that defines the domain to be meshed as follows. The constrained edges of *t* partition the plane into connected components. If *mark=true*, the mesh domain is the union of the bounded connected components including at least one seed. If *mark=false*, the domain is the union of the bounded components including no seed. Note that the unbounded component of the plane is never meshed.

Requirement: The *value_type* of *begin* and *end* is *CDT::Geom_traits::Point_2*.

CGAL::Triangulation_conformer_2<CDT>

The class *Triangulation_conformer_2<CDT>* is an auxiliary class of *Delaunay_mesher_2<CDT>*. It permits to refine a constrained Delaunay triangulation into a conforming Delaunay or conforming Gabriel triangulation. For standard needs, consider using the global functions *make_conforming_Gabriel_2* and *make_conforming_Delaunay_2*.

```
#include <CGAL/Triangulation_conformer_2.h>
```

Parameters

The template parameter *CDT* should be a model of the concept *ConstrainedDelaunayTriangulation_2*.

The geometric traits class of the instance of *CDT* has to be a model of the concept *ConformingDelaunayTriangulationTraits_2*.

Using this class

The constructor of the class *Triangulation_conformer_2<CDT>* takes a reference to a *CDT* as an argument. A call to the method *make_conforming_Delaunay()* or *make_conforming_Gabriel()* will refine this constrained Delaunay triangulation into a conforming Delaunay or conforming Gabriel triangulation. Note that if, during the life time of the *Triangulation_conformer_2<CDT>* object, the triangulation is externally modified, any further call to its member methods may lead to undefined behavior. Consider reconstructing a new *Triangulation_conformer_2<CDT>* object if the triangulation has been modified.

The conforming methods insert points into constrained edges, thereby splitting them into several sub-constraints. You have access to the initial inserted constraints if you instantiate the template parameter by a *CGAL::Constrained_triangulation_plus_2<CDT>*.

Creation

```
Triangulation_conformer_2<CDT> m( CDT& t);
```

Create a new conforming maker, working on *t*.

Operations

Conforming methods

```
void m.make_conforming_Delaunay()
```

Refines the triangulation into a conforming Delaunay triangulation. After a call to this method, all triangles fulfill the Delaunay property, that is the empty circle property.

void *m.make_conforming_Gabriel()*

Refines the triangulation into a conforming Gabriel triangulation. After a call to this method, all constrained edges *e* have the *Gabriel property*: the circle with diameter *e* does not contain any vertex of the triangulation.

Checking

The following methods verify that the constrained triangulation is conforming Delaunay or conforming Gabriel. These methods scan the whole triangulation and their complexity is proportional to the number of edges.

bool *m.is_conforming_Delaunay()*

Returns *true* iff all triangles fulfill the Delaunay property.

bool *m.is_conforming_Gabriel()*

Returns *true* iff all constrained edges have the Gabriel property: their circumsphere is empty.

— *advanced* —

Step by step operations

The *Triangulation_conformer_2<CDT>* class allows, for debugging or demos, to play the conforming algorithm step by step, using the following methods. They exist in two versions, depending on whether you want the triangulation to be conforming Delaunay or conforming Gabriel, respectively. Any call to a *step_by_step_conforming_XX* function requires a previous call to the corresponding function *init_XX* and Gabriel and Delaunay methods can not be mixed between two calls of *init_XX*.

void *m.init_Delaunay()*

The method must be called after all points and constrained segments are inserted and before any call to the following methods. If some points or segments are then inserted in the triangulation, this method must be called again.

bool *m.step_by_step_conforming_Delaunay()*

Applies one step of the algorithm, by inserting one point, if the algorithm is not done. Returns *false* iff no point has been inserted because the algorithm is done.

void *m.init_Gabriel()*

Analog to *init_Delaunay* for Gabriel conforming.

bool *m.step_by_step_conforming_Gabriel()*

Analog to *step_by_step_conforming_Delaunay()* for Gabriel conforming.

bool

m.is_conforming_done()

Tests if the step by step conforming algorithm is done. If it returns *true*, the following calls to *step_by_step_conforming_XX* will not insert any points, until some new constrained segments or points are inserted in the triangulation and *init_XX* is called again.

46.1 Introduction

This package provides a function template to compute a triangular mesh approximating a surface.

The meshing algorithm requires to know the surface to be meshed only through an oracle able to tell whether a given segment, line or ray intersects the surface or not and to compute an intersection point if any. This feature makes the package generic enough to be applied in a wide variety of situations. For instance, it can be used to mesh implicit surfaces described as the zero level set of some function. It may also be used in the field of medical imaging to mesh surfaces described as a gray level set in a three dimensional image.

The meshing algorithm is based on the notion of the restricted Delaunay triangulation. Basically the algorithm computes a set of sample points on the surface, and extract an interpolating surface mesh from the three dimensional triangulation of these sample points. Points are iteratively added to the sample, as in a Delaunay refinement process, until some size and shape criteria on the elements of the surface mesh are satisfied.

The size and shape criteria guide the behavior of the refinement process and control its termination. They also condition the size and shape of the elements in the final mesh. Naturally, those criteria can be customized to satisfy the user needs. The *Surface mesh generation* package offers a set of standard criteria that can be scaled through three numerical values. Also the user can also plug in its own set of refinement criteria.

There is no restriction on the topology and number of components of the surface provided that the oracle (or the user) is able to provide one initial sample point on each connected component. If the surface is smooth enough, and if the size criteria are small enough, the algorithm guarantees that the output mesh is homeomorphic to the surface, and is within a small bounded distance (Hausdorff or even Frechet distance) from the surface. The algorithm can also be used for non smooth surfaces but then there is no guarantee.

46.2 The Surface Mesh Generator Interface for Smooth Surfaces

The meshing process is launched through a call to a function template. There are two overloaded versions of the meshing function whose signatures are the following:

```
template <class SurfaceMeshC2T3, class Surface, class FacetsCriteria, class Tag >
void make_surface_mesh(
    SurfaceMeshC2T3& c2t3,
    Surface surface,
    FacetsCriteria criteria,
    Tag)
```

```
template <class SurfaceMeshC2T3, class SurfaceMeshTraits, class FacetsCriteria, class Tag >
void make_surface_mesh(
    SurfaceMeshC2T3& c2t3,
    SurfaceMeshTraits::Surface_3 surface,
    SurfaceMeshTraits traits,
    FacetsCriteria criteria,
    Tag)
```

The template parameter *SurfaceMeshC2T3* stands for a data structure type that is used to store the surface mesh. This type is required to be a model of the concept *SurfaceMeshComplex_2InTriangulation_3*. Such a data structure has a pointer to a three dimensional triangulation and encodes the surface mesh as a subset of facets in this triangulation. An argument of type *SurfaceMeshC2T3* is passed by reference to the meshing function. This argument holds the output mesh at the end of the process.

The template parameter *Surface* stands for the surface type. This type has to be a model of the concept *Surface_3*.

The knowledge on the surface, required by the surface mesh generator is encapsulated in a traits class. Actually, the mesh generator accesses the surface to be meshed through this traits class only. The traits class is required to be a model of the concept *SurfaceMeshTraits_3*. The difference between the two overloaded versions of *make_surface_mesh* can be explained as follows

- In the first overloaded version of *make_surface_mesh*, the surface type is given as template parameter (*Surface*) and the *surface* to be meshed is passed as parameter to the mesh generator. In that case the surface mesh generator traits type is automatically generated from the surface type by an auxiliary class called the *Surface_mesh_traits_generator_3*.
- In the second overloaded version of *make_surface_mesh*, the surface mesh generator traits type is provided by the template parameter *SurfaceMeshTraits_3* and the surface type is obtained from this traits type. Both a surface and a traits are passed to the mesh generator as arguments.

The first overloaded version can be used whenever the surface type either provides a nested type *Surface::Surface_mesher_traits_3* that is a model of *SurfaceMeshTraits_3* or is a surface type for which a specialization of the traits generator *Surface_mesh_traits_generator_3<Surface>* is provided. Currently, the library provides partial specializations of *Surface_mesher_traits_generator_3<Surface>* for implicit surfaces (*Implicit_surface_3<Traits, Function>*) and gray level images (*Gray_level_image_3<FT, Point>*).

The parameter *criteria* handles the description of the size and shape criteria driving the meshing process. The template parameter *FacetsCriteria* has to be instantiated by a model of the concept *SurfaceMeshFacetsCriteria*.

The parameter *Tag* is a tag whose type influences the behavior of the meshing algorithm. For instance, this parameter can be used to enforce the manifold property of the output mesh while avoiding an over-refinement of the mesh. Further details on this subject are given in Section [46.4](#).

A call to *make_surface_mesh(c2t3, surface, criteria, tag)* launches the meshing process with an initial set of points which is the union of two subsets: the set of vertices in the initial triangulation pointed to by *c2t3*, and a set of points provided by the *Compute_initial_points()* functor of the traits class. This initial set of points is required to include at least one point on each connected component of the surface to be meshed.

46.3 Examples

46.3.1 Meshing Isosurfaces defined by Implicit Functions

The first code example meshes a sphere given as the zero level set of a function $\mathbb{R}^3 \longrightarrow \mathbb{R}$. More precisely, the surface to be meshed is created by the constructor of the class *Implicit_surface_3<Kernel, Function>* from a pointer to the function (*sphere_function*) and a bounding sphere.

The default meshing criteria are determined by three numerical values:

- *angular_bound* is a lower bound in degrees for the angles of mesh facets.
- *radius_bound* is an upper bound on the radii of surface Delaunay balls. A surface Delaunay ball is a ball circumscribing a mesh facet and centered on the surface.
- *distance_bound* is an upper bound for the distance between the circumcenter of a mesh facet and the center of a surface Delaunay ball of this facet.

Given this surface type, the surface mesh generator will use an automatically generated traits class.

The resulting mesh is shown in Figure [46.1](#).

```
#include <CGAL/Surface_mesh_default_triangulation_3.h>
#include <CGAL/Complex_2_in_triangulation_3.h>
#include <CGAL/make_surface_mesh.h>
#include <CGAL/Implicit_surface_3.h>

// default triangulation for Surface_mesher
typedef CGAL::Surface_mesh_default_triangulation_3 Tr;

// c2t3
typedef CGAL::Complex_2_in_triangulation_3<Tr> C2t3;

typedef Tr::Geom_traits GT;
typedef GT::Sphere_3 Sphere_3;
typedef GT::Point_3 Point_3;
typedef GT::FT FT;

typedef FT (*Function) (Point_3);

typedef CGAL::Implicit_surface_3<GT, Function> Surface_3;

FT sphere_function (Point_3 p) {
```

```

const FT x2=p.x()*p.x(), y2=p.y()*p.y(), z2=p.z()*p.z();
return x2+y2+z2-1;
}

int main() {
    Tr tr;           // 3D-Delaunay triangulation
    C2t3 c2t3 (tr);  // 2D-complex in 3D-Delaunay triangulation

    // defining the surface
    Surface_3 surface(sphere_function,           // pointer to function
                     Sphere_3(CGAL::ORIGIN, 2.)); // bounding sphere
    // Note that "2." above is the *squared* radius of the bounding sphere!

    // defining meshing criteria
    CGAL::Surface_mesh_default_criteria_3<Tr> criteria(30., // angular
                                                       bound
                                                       0.1, // radius
                                                       bound
                                                       0.1); // distance
    // meshing surface
    CGAL::make_surface_mesh(c2t3, surface, criteria,
                           CGAL::Non_manifold_tag());

    std::cout << "Final number of points: " << tr.number_of_vertices() <<
        "\n";
}

```

```
}
```

File: examples/Surface_mesher/mesh_an_implicit_function.cpp

46.3.2 Meshing Isosurfaces Defined as Gray Levels in 3D Images

In this example the surface to be meshed is defined as the locus of points with a given gray level in a 3D image. The code is quite similar to the previous example.

The main difference with the previous code is that the function used to define the surface is an object of type `CGAL::Gray_level_image_3` created from an image file and a numerical value that is the gray value of the level one wishes to mesh.

Note that surface, which is still an object of type `Implicit_surface_3` is now, defined by three parameters that are the function, the bounding sphere and a numerical value called *the precision*. This precision, whose value is relative to the bounding sphere radius, is used in the intersection computation. This parameter has a default which was used in the previous example. Also note that the center of the bounding sphere is required to be internal a point where the function has a negative value.

The chosen iso-value of this 3D image corresponds to a head skull. The resulting mesh is shown in Figure 46.2.

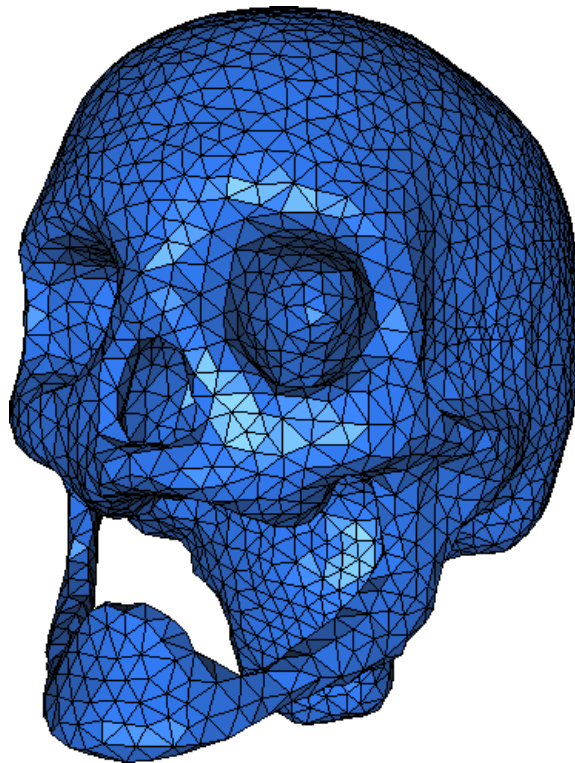

Figure 46.2: Surface mesh of an iso-contour extracted from a gray level 3D image

```
#include <CGAL/Surface_mesh_default_triangulation_3.h>
#include <CGAL/Surface_mesh_default_criteria_3.h>
#include <CGAL/Complex_2_in_triangulation_3.h>
```

```

#include <CGAL/IO/Complex_2_in_triangulation_3_file_writer.h>
#include <fstream>
#include <CGAL/make_surface_mesh.h>
#include <CGAL/Gray_level_image_3.h>
#include <CGAL/Implicit_surface_3.h>

// default triangulation for Surface_mesher
typedef CGAL::Surface_mesh_default_triangulation_3 Tr;

// c2t3
typedef CGAL::Complex_2_in_triangulation_3<Tr> C2t3;

typedef Tr::Geom_traits GT;
typedef CGAL::Gray_level_image_3<GT::FT, GT::Point_3> Gray_level_image;
typedef CGAL::Implicit_surface_3<GT, Gray_level_image> Surface_3;

int main() {
    Tr tr;                // 3D-Delaunay triangulation
    C2t3 c2t3 (tr);       // 2D-complex in 3D-Delaunay triangulation

46.4 Meshing Criteria, Guarantees and Variations

The guarantees on the output mesh depend on the mesh criteria. Theoretical guarantees are given in [BO05]. First, the meshing algorithm is proved to terminate if the lower bound on facets angles is not bigger than 30 degrees. Furthermore, the output mesh is guaranteed to be homeomorphic to the surface, and there is a guaranteed bound on the distance (Hausdorff and even Frechet distance) between the mesh and the surface if the radius bound is everywhere smaller than ϵ times the local feature size. Here ϵ is a constant that has to be less than 0.16, and the local feature size $lfs(x)$ is defined on each point x of the surface as the distance from x to the medial axis. Note that the radius bound need not be uniform, although it is a uniform bound in the default criteria.

Naturally, such a theoretical guarantee can be only achieved for smooth surfaces that have a finite, non zero reach value. (The reach of a surface is the minimum value of local feature size on this surface).

The value of the local feature size on any point of the surface or its minimum on the surface it usually unknown although it can sometimes be guessed. Also it happens frequently that setting the meshing criteria so as to fulfill the theoretical conditions yields an over refined mesh. On the other hand, when the size criteria are relaxed, no homeomorphism with the input surface is guaranteed, and the output mesh is not even guaranteed to be manifold. To remedy this problem and give a more flexible meshing algorithm, the function template *make_surface_mesh* has a tag template parameter allowing to slightly change the behavior of the refinement process. This feature allows, for instance, to run the meshing algorithm with a relaxed size criteria, more coherent with the size of the mesh expected by the user, and still have a guarantee that the output mesh forms a manifold surface. The function *make_surface_mesh* has specialized versions for the following tag types:

Manifold_tag: the output mesh is guaranteed to be a manifold surface without boundary.

Manifold_with_boundary_tag: the output mesh is guaranteed to be manifold but may have boundaries.

Non_manifold_tag: the algorithm relies on the given criteria and guarantees nothing else.

46.5 Output

This CGAL component also provides functions to write the reconstructed surface mesh to the Object File Format (OFF) [Phi96] and to convert it to a polyhedron (when it is manifold):

CGAL::output_surface_facets_to_off

CGAL::output_surface_facets_to_polyhedron

46.6 Undocumented Features Available in Demos

The Polyhedron demo has a feature that allows to remesh a polyhedral surface, using the 3D Surface Mesh Generator. That has been implemented as a special model of *SurfaceMeshTraits_3*, for polyhedra. That traits class is not yet documented because its interface and code have not yet been stabilized. It will probably be shipped with next release of CGAL.

The Surface Mesh Generator demo allows to mesh not only gray level images, but also segmented images, when voxels are labelled with a domain index. Such images are for example the result of a segmentation of 3D medical images. This feature is not yet ready to be documented in current release, but will probably be in next release of CGAL.

46.7 Design and Implementation History

The algorithm implemented in this package is mainly based on the work of Jean-Daniel Boissonnat and Steve Oudot [BO05]. Steve Oudot implemented a first working prototype of the algorithm during his PhD thesis.

The meshing algorithm is implemented using the design of mesher levels described in [RY07].

David Rey, Steve Oudot and Andreas Fabri have participated in the development of this package.

3D Surface Mesh Generation

Reference Manual

Laurent Rineau and Mariette Yvinec

The surface mesh generation package offers a function template which builds a triangular mesh approximating a surface.

The meshing algorithms requires to know the surface to be meshed through an oracle that mainly can tell whether a given segment, ray or line intersects the surface or not and can compute the intersections point if any. The oracle is represented by a traits class which can be passed to the meshing function or automatically generated for certain types of surfaces. The current implementation provides traits classes to mesh implicit surfaces as well as surfaces described as a gray level in a three dimensional image.

The output mesh conforms to some size and shape criteria which are customizable. The criteria are passed to the mesher through a parameter whose type is a model of the concept *SurfaceMeshFacetsCriteria_3*.

The meshing algorithm is a Delaunay refinement process which is mainly guided by the criteria. The output mesh may offer some guarantees, as being manifold, homeomorphic to the surface or within a given Hausdorff distance. However, these guarantees depend on the quality of the input surface (smoothness, with or without boundary, manifold or not), the type and values of the given criteria. The behavior of the refinement process can also be influenced through a tag, which allows for instance to enforce the manifold property of the output mesh while avoiding an over-refinement of the mesh.

CGAL::Gray_level_image_3<FT, Point>

Definition

A 3D gray image is a tri-dimensional array that associates a scalar value to each triple of integer (x, y, z) in the range of the image. A trilinear interpolation algorithm provides a map $f : \mathbb{R}^3 \longrightarrow \mathbb{R}$.

The class *Gray_level_image_3<FT, Point>* is a 3D gray image loader and a model of the concept *ImplicitFunction*. An object of the class *Gray_level_image_3<FT, Point>* is created with a parameter *iso* and then its *operator()* implements the function *sign of (f(p) - iso)*, for $p \in \mathbb{R}^3$. Plugging such a function in the creation of the *Implicit_surface_3* object given as parameter to *make_surface_mesh* yields a mesh approximating the level with value *iso* in the input 3D gray image.

Gray_level_image_3<FT, Point> provides an interface with an auxiliary library called *CGALImageIO*. An executable that uses *Gray_level_image_3<FT, Point>* must be linked with the *CGALImageIO* library. This library is shipped with CGAL and will be linked automatically by any makefile created by the script *cgal_create_makefile*.

The library *CGALImageIO* and therefore *Gray_level_image_3<FT, Point>* support several types of 3D images: INRIMAGE (extension *.inr[.gz]*), GIS (extension *.dim*, of *.ima[.gz]*), and ANALYZE (extension *.hdr*, or *.img[.gz]*).

```
#include <CGAL/Gray_level_image_3.h>
```

Is Model for the Concepts

ImplicitFunction

Types

Gray_level_image_3<FT, Point>:: FT the numerical type *FT*

Gray_level_image_3<FT, Point>:: Point the point type *Point*

Creation

```
Gray_level_image_3<FT, Point> image( const char* filename, FT iso_value);
```

filename is the path to a file of a type supported by *ImageIO*.
iso_value is an isovalue of *f*.

CGAL::Implicit_surface_3<Traits, Function>

Definition

The class *Implicit_surface_3*<*Traits*, *Function*> implements a surface described as the zero level set of a function $f : \mathbb{R}^3 \longrightarrow \mathbb{R}$.

For this type of surface, the library provides a partial specialization of the surface mesher traits generator: *Surface_mesh_traits_generator_3*<*Implicit_surface_3*<*Traits*, *Function*> >, that provides a traits class, model of the concept *SurfaceMeshTraits_3*, to be used by the surface mesher.

The parameter *Traits* is a traits class that has to be implemented with a model of *ImplicitSurfaceTraits_3*. Actually, this traits class implements the oracle needed by the surface mesher: the types, predicates and constructors provided in *Traits* are passed by the surface mesher traits generator to the generated the traits class used by the surface mesh generator.

The template parameter *Function* stands for a model of the concept *ImplicitFunction*. The number type *Function::FT* has to match the type *Traits::FT*.

```
#include <CGAL/Implicit_surface_3.h>
```

Creation

```
Implicit_surface_3<Traits, Function> surface( Function f,
                                             Sphere_3 bounding_sphere,
                                             FT error_bound = FT(1e-3))
```

f is the object of type *Function* that represents the implicit surface.

bounding_sphere is a bounding sphere of the implicit surface. The evaluation of *f* at the center *c* of this sphere must be negative: $f(c) < 0$.

error_bound is a relative error bound used to compute intersection points between the implicit surface and query segments. This bound is used in the default generated traits class. In this traits class, the intersection points between the surface and segments/rays/line are constructed by dichotomy. The dichotomy is stopped when the size of the intersected segment is less than the product of *error_bound* by the radius of *bounding_sphere*.

ImplicitSurfaceTraits_3

Definition

The concept `ImplicitSurfaceTraits_3` describes the requirements of the traits class to be plugged as *Traits* in `Implicit_surface_3<Traits, Function>`.

When `make_surface_mesh` is called with a surface of type `Implicit_surface_3<Traits,Function>`, the surface mesher traits generator generates automatically a traits class that is a model of `SurfaceMeshTraits_3`. Actually, the concept `ImplicitSurfaceTraits_3` provides the types, predicates and constructors that are passed to the generated model of `SurfaceMeshTraits_3`.

Types

<code>ImplicitSurfaceTraits_3:: FT</code>	The numerical type. It must be model of <i>SqrtFieldNumber-Type</i> and constructible from a <i>double</i> .
<code>ImplicitSurfaceTraits_3:: Point_3</code>	The point type. This point type must have a constructor <code>Point_3(FT, FT, FT)</code> .
<code>ImplicitSurfaceTraits_3:: Line_3</code>	The line type.
<code>ImplicitSurfaceTraits_3:: Ray_3</code>	The ray type.
<code>ImplicitSurfaceTraits_3:: Segment_3</code>	The segment type.
<code>ImplicitSurfaceTraits_3:: Vector_3</code>	The vector type.
<code>ImplicitSurfaceTraits_3:: Sphere_3</code>	The sphere type.

`ImplicitSurfaceTraits_3:: Compute_scalar_product_3`

A function object that provides the operator
`FT operator()(Vector_3 v, Vector_3 w)` which returns the scalar (inner) product of the two vectors *v* and *w*.

`ImplicitSurfaceTraits_3:: Compute_squared_distance_3`

A function object that provides the operator
`FT operator()(Point_3, Point_3)` which returns the squared distance between two points.

`ImplicitSurfaceTraits_3:: Compute_squared_radius_3`

A function object providing the operator
`FT operator()(const Sphere_3& s)` which returns the squared radius of *s*.

`ImplicitSurfaceTraits_3:: Construct_center_3`

A function object providing the operator
`Point_3 operator()(const Sphere_3& s)` which computes the center of the sphere *s*.

ImplicitSurfaceTraits_3:: Construct_midpoint_3

A function object providing the operator

Point_3 operator()(const Point_3& p, const Point_3& q) which computes the midpoint of the segment pq .

ImplicitSurfaceTraits_3:: Construct_point_on_3

A function object providing the following operators:

Point_3 operator()(const Line_3& l, int i); which returns an arbitrary point on l . It holds $point(i) == point(j)$, iff $i=j$. Furthermore, is directed from $point(i)$ to $point(j)$, for all $i < j$.

Point_3 operator()(const Ray_3& r, int i); which returns a point on r . $point(0)$ is the source, $point(i)$, with $i > 0$, is different from the source.

Precondition: $i \geq 0$.

Point_3 operator()(const Segment_3& s, int i); which returns source or target of s : $point(0)$ returns the source of s , $point(1)$ returns the target of s . The parameter i is taken modulo 2, which gives easy access to the other end point.

ImplicitSurfaceTraits_3:: Construct_segment_3

A function object providing the operators

Segment_3 operator()(const Point_3& p, const Point_3& q); which returns a segment with source p and target q . It is directed from the source towards the target.

ImplicitSurfaceTraits_3:: Construct_scaled_vector_3

A function object providing the operator

Vector_3 operator()(const Vector_3& v, const FT& scale) which returns the vector v scaled by a factor $scale$.

ImplicitSurfaceTraits_3:: Construct_translated_point_3

A function object providing the operator

Point_3 operator()(const Point_3& p, const Vector_3& v) which returns the point obtained by translating p by the vector v .

ImplicitSurfaceTraits_3:: Construct_vector_3

A function object providing the operator

Vector_3 operator()(const Point_3& a, const Point_3& b) which returns the vector $b-a$.

ImplicitSurfaceTraits_3:: Has_on_bounded_side_3

A function object providing the operator

bool operator()(const Sphere_3& s, const Point_3& p); which returns true iff p lies on the bounded side of s .

Operations

The following functions give access to the predicate and construction objects:

<i>Compute_scalar_product_3</i>	<i>traits.compute_scalar_product_3_object()</i>
<i>Compute_squared_distance_3</i>	<i>traits.compute_squared_distance_3_object()</i>
<i>Compute_squared_radius_3</i>	<i>traits.compute_squared_radius_3_object()</i>
<i>Construct_center_3</i>	<i>traits.construct_center_3_object()</i>
<i>Construct_midpoint_3</i>	<i>traits.construct_midpoint_3_object()</i>
<i>Construct_point_on_3</i>	<i>traits.construct_point_on_3_object()</i>
<i>Construct_scaled_vector_3</i>	<i>traits.construct_scaled_vector_3_object()</i>
<i>Construct_segment_3</i>	<i>traits.construct_segment_3_object()</i>
<i>Construct_translated_point_3</i>	<i>traits.construct_translated_point_3_object()</i>
<i>Construct_vector_3</i>	<i>traits.construct_vector_3_object()</i>
<i>Has_on_bounded_side_3</i>	<i>traits.has_on_bounded_side_3_object()</i>

Has Models

Any CGAL Kernel.

make_surface_mesh

CGAL::make_surface_mesh

```
#include <CGAL/make_surface_mesh.h>
```

Definition

The function *make_surface_mesh* is a surface mesh generator, that is a function to build a two dimensional mesh approximating a surface.

The library provides two overloaded version of this function:

```
template <class SurfaceMeshC2T3, class Surface, class FacetsCriteria, class Tag >
void      make_surface_mesh( SurfaceMeshC2T3& c2t3,
                           Surface surface,
                           FacetsCriteria criteria,
                           Tag,
                           int initial_number_of_points = 20)
```

```
template <class SurfaceMeshC2T3, class SurfaceMeshTraits, class FacetsCriteria, class Tag >
void      make_surface_mesh( SurfaceMeshC2T3& c2t3,
                           SurfaceMeshTraits::Surface_3 surface,
                           SurfaceMeshTraits traits,
                           FacetsCriteria criteria,
                           Tag,
                           int initial_number_of_points = 20)
```

Parameters

The template parameter *SurfaceMeshC2T3* is required to be a model of the concept *SurfaceMeshComplex_2InTriangulation_3*, a data structure able to represent a two dimensional complex embedded in a three dimensional triangulation. The argument *c2t3* of type *SurfaceMeshC2T3*, passed by reference to the surface mesh generator, is used to maintain the current approximating mesh and it stores the final mesh at the end of the procedure. The type *SurfaceMeshC2T3* is in particular required to provide a type *SurfaceMeshC2T3::Triangulation_3* for the three dimensional triangulation embedding the surface mesh. The vertex and cell base classes of the triangulation *SurfaceMeshC2T3::Triangulation_3* are required to be models of the concepts *SurfaceMeshVertexBase_3* and *SurfaceMeshCellBase_3* respectively.

The template parameter *Surface* stands for the surface type. This type has to be a model of the concept *Surface_3*.

The knowledge on the surface, required by the surface mesh generator is encapsulated in a traits class. Actually, the mesh generator accesses the surface to be meshed through this traits class only. The traits class is required to be a model of the concept *SurfaceMeshTraits_3*.

In the first version of *make_surface_mesh* the surface type is a template parameter *Surface* and the surface mesh generator traits type is automatically generated from the surface type through the class *Surface_mesh_traits_generator_3<Surface>*.

The difference between the two overloaded versions of *make_surface_mesh* can be explained as follows

- In the first overloaded version of *make_surface_mesh*, the surface type is given as template parameter (*Surface*) and the *surface* to be meshed is passed as parameter to the mesh generator. In that case the surface mesh generator traits type is automatically generated from the surface type by an auxiliary class called the *Surface_mesh_traits_generator_3*.
- In the second overloaded version of *make_surface_mesh*, the surface mesh generator traits type is provided by the template parameter *SurfaceMeshTraits_3* and the surface type is obtained from this traits type. Both the surface and the traits are passed to the mesh generator as arguments.

The first overloaded version can be used whenever the surface type either provides a nested type *Surface::Surface_mesher_traits_3* that is a model of *SurfaceMeshTraits_3* or is a surface type for which a specialization of the traits generator *Surface_mesh_traits_generator_3*<*Surface*> is provided. Currently, the library provides partial specializations of *Surface_mesher_traits_generator_3*<*Surface*> for implicit surfaces (*Implicit_surface_3*<*Traits*, *Function*>) and gray level images (*Gray_level_image_3*<*FT*, *Point*>).

The template parameter *FacetsCriteria* has to be a model of the concept *SurfaceMeshFacetsCriteria_3*. The argument of type *FacetsCriteria* passed to the surface mesh generator specifies the size and shape requirements on the output surface mesh.

The template parameter *Tag* is a tag whose type affects the behavior of the meshing algorithm. The function *make_surface_mesh* has specialized versions for the following tag types:

- *Manifold_tag*: the output mesh is guaranteed to be a manifold surface without boundary.
- *Manifold_with_boundary_tag*: the output mesh is guaranteed to be manifold but may have boundaries.
- *Non_manifold_tag*: the algorithm relies on the given criteria and guarantees nothing else.

The Delaunay refinement process is started with an initial set of points which is the union of two sets: the set of vertices in the initial triangulation pointed to by the *c2t3* argument and a set of points provided by the traits class. The optional parameter *initial_number_of_points* allows to monitor the number of points in this second set. (This parameter is passed to the *operator()* of the constructor object *Construct_initial_points* in the traits class.) The meshing algorithm requires that the initial set of points includes at least one point on each connected components of the surface to be meshed. one.

Surface_3

Definition

The concept `Surface_3` describes the types of surfaces to be meshed. The surface types are required to be copy constructible and assignable.

Types

In addition, surface types are required

- either to provide a nested type: `Surface_3:: Surface_mesher_traits_3` a model of `SurfaceMesherTraits_3`
- or to be a surface type for which a specialization of the traits generator `Surface_mesh_traits_generator_3<Surface>` exists.

SurfaceMeshCellBase_3

Definition

The concept `SurfaceMeshCellBase_3` describes the cell base type of the three dimensional triangulation used to embed the surface mesh.

More precisely, the first template parameter `SurfaceMeshC2T3` of the surface mesher `make_surface_mesh` is a model of the concept `SurfaceMeshComplex_2InTriangulation_3` which describes a data structure to store a pure two dimensional complex embedded in a three dimensional triangulation. In particular, the type `SurfaceMeshC2T3` is required to provide a three dimensional triangulation type `SurfaceMeshC2T3::Triangulation_3`. The concept `SurfaceMeshCellBase_3` describes the cell base type required in this triangulation type.

Refines

TriangulationCellBase_3

The concept `SurfaceMeshCellBase_3` adds four markers to mark the facets of the triangulation that belong to the two dimensional complex, and four markers that are helpers used in some operations to mark for instance the facets that have been visited.

This concept also provides storage for the center of a Delaunay surface ball. Given a surface and a 3D Delaunay triangulation, a Delaunay surface ball is a ball circumscribed to a facet of the triangulation and centered on the surface and empty of triangulation vertices. Such a ball does exist when the facet is part of the restriction to the surface of a three dimensional triangulation. In the following we call *surface center* of a facet, the center of its biggest Delaunay surface ball.

Types

SurfaceMeshCellBase_3::Point

The point type, required to match the point type of the three dimensional triangulation in which the surface mesh is embedded.

Creation

Operations

bool `cell.is_facet_on_surface(int i)`

returns *true*, if *facet(i)* is in the 2D complex.

void `cell.set_facet_on_surface(int i, bool b)`

Sets *facet(i)* as part of the 2D complex, if *b* is *true*, and *NOT_IN_COMPLEX*, otherwise.

bool `cell.is_facet_visited(int i)`

Returns *true*, if *facet(i)* has been visited, *false* otherwise.

void *cell.set_facet_visited(int i, bool b)*

Marks *facet(i)* as visited, if *b* is *true*, and non visited otherwise.

Point *cell.get_facet_surface_center(int i)*

Returns a const reference to the surface center of *facet(i)*.

void *cell.set_facet_surface_center(int i, Point p)*

Sets point *p* as the surface center of *facet(i)*.

CGAL::Surface_mesh_complex_2_in_triangulation_3<Tr, Edge_info = void>

Definition

The class *Surface_mesh_complex_2_in_triangulation_3*<*Tr*, *Edge_info* = *void*> implements a data structure to store the restricted Delaunay triangulation used by the surface mesh generator. The restricted Delaunay triangulation is stored as a two dimensional complex embedded in a three dimensional triangulation.

The class *Surface_mesh_complex_2_in_triangulation_3*<*Tr*, *Edge_info* = *void*> is a model of the concept *SurfaceMeshComplex_2InTriangulation_3* and can be plugged as the template parameter *C2T3* in the function template *make_surface_mesh*.

The template parameter *Tr* has to be instantiated with a model of the concept *SurfaceMeshTriangulation_3*. (Any three dimensional triangulation of CGAL is a model of *Triangulation_3* provided that its vertex and cell base class be models of the concept *SurfaceMeshVertexBase_3* and *SurfaceMeshCellBase_3* respectively.)

SurfaceMeshTriangulation_3

SurfaceMeshComplex_2InTriangulation_3

Definition

The concept `SurfaceMeshComplex_2InTriangulation_3` describes a data structure designed to represent a two dimensional pure complex embedded in a three dimensional triangulation.

A *complex* is a set C of faces such that:

- any subface of a face in C is a face of C
- two faces of C are disjoint or share a common subface

The complex is *two dimensional*, if its faces have dimension at most two. It is *pure* if any face in the complex is a subface of some face of maximal dimension. Thus, a two dimensional pure complex is a set of facets together with their edges and vertices. A two dimensional pure complex embedded in a three dimensional triangulation is a subset of the facets of this triangulation, together with their edges and vertices.

The concept `SurfaceMeshComplex_2InTriangulation_3` is particularly suited to handle surface meshes obtained as the restriction to a surface of a three dimensional Delaunay triangulation. A model of this concept is a type to be plugged as first template parameter in the function template `make_surface_mesh`.

Types

`SurfaceMeshComplex_2InTriangulation_3` provides the following types.

SurfaceMeshComplex_2InTriangulation_3::Triangulation

The type of the embedding 3D triangulation. Must be a model of `SurfaceMeshTriangulation_3`.

typedef Triangulation::Vertex_handle

Vertex_handle;
typedef Triangulation::Cell_handle

The type of the embedding triangulation vertex handles.

Cell_handle;
typedef Triangulation::Facet

The type of the embedding triangulation cell handles.

Facet;
typedef Triangulation::Edge

The type of the embedding triangulation facets.

Edge;
typedef Triangulation::size_type

The type of the embedding triangulation edges.

size_type;

Size type (an unsigned integral type)

enum Face_status { NOT_IN_COMPLEX, BOUNDARY, REGULAR, SINGULAR};

A type to describe the status of a face (facet, edge, or vertex) with respect to the 2D pure complex. A *NOT_IN_COMPLEX* face does not belong to the 2D complex. Facets can only be *NOT_IN_COMPLEX* or *REGULAR* depending on whether they belong to the 2D complex or not. Edges and vertices can be *NOT_IN_COMPLEX*, *BOUNDARY*, *REGULAR* or *SINGULAR*. An edge in the complex is *BOUNDARY*, *REGULAR*, or *SINGULAR*, if it is incident to respectively 1, 2, or 3 or more facets in the complex. The status of a vertex is determined by the adjacency graph of the facets of the 2D complex incident to that vertex. The vertex of the 2D complex is *BOUNDARY*, if this adjacency graph is a simple path, it is *REGULAR*, if the adjacency graph is cyclic, and *SINGULAR* in any other case.

SurfaceMeshComplex_2InTriangulation_3:: Facet_iterator

An iterator type to visit the facets of the 2D complex.

SurfaceMeshComplex_2InTriangulation_3:: Edge_iterator

An iterator type to visit the edges of the 2D complex.

SurfaceMeshComplex_2InTriangulation_3:: Vertex_iterator

An iterator type to visit vertices of the 2D complex.

SurfaceMeshComplex_2InTriangulation_3:: Boundary_edges_iterator

An iterator type to visit the boundary edges of the 2D complex.

Creation

SurfaceMeshComplex_2InTriangulation_3 c2t3(Triangulation& t3);

Builds an empty 2D complex embedded in the triangulation *t3*

template < class FacetSelector>

SurfaceMeshComplex_2InTriangulation_3 c2t3(Triangulation& t3, FacetSelector select);

Builds a 2D complex embedded in the triangulation *t3*, including in the 2D complex the facets of *t3* for which the predicate *select* returns *true*.

The type *FacetSelector* must be a function object with an operator to select facets: *bool operator()(Facet f);*

Member access

Triangulation & *c2t3.triangulation()* Returns the reference to the triangulation.

Modifications

void *c2t3.add_to_complex(Facet f)*
Adds facet *f* to the 2D complex.

void *c2t3.add_to_complex(Cell_handle c, int i)*
Adds facet *(c,i)* to the 2D complex.

void *c2t3.remove_from_complex(Facet f)*
Removes facet *f* from the 2D complex.

void *c2t3.remove_from_complex(Cell_handle c, int i)*
Removes facet *(c,i)* from the 2D complex.

Queries

Queries on the status of individual face with respect to the 2D complex.

size_type *c2t3.number_of_facets()*
Returns the number of facets that belong to the 2D complex.

Face_status *c2t3.face_status(Facet f)*
Returns the status of the facet *f* with respect to the 2D complex.

Face_status *c2t3.face_status(Cell_handle c, int i)*
Returns the status of the facet *(c,i)* with respect to the 2D complex.

Face_status *c2t3.face_status(Edge e)*
Returns the status of edge *e* in the 2D complex.

Face_status *c2t3.face_status(Cell_handle c, int i, int j)*
Returns the status of edge *(c,i,j)* in the 2D complex.

Face_status *c2t3.face_status(Vertex_handle v)*
Returns the status of vertex *v* in the 2D complex.

bool *c2t3.is_in_complex(Facet f)*
Returns *true*, if the facet *f* belongs to the 2D complex.

<i>bool</i>	<i>c2t3.is_in_complex(Cell_handle c, int i)</i>	Returns <i>true</i> , if the facet (c,i) belongs to the 2D complex.
<i>bool</i>	<i>c2t3.is_in_complex(Edge e)</i>	Returns <i>true</i> , if the edge e belongs to the 2D complex.
<i>bool</i>	<i>c2t3.is_in_complex(Cell_handle c, int i, int j)</i>	Returns <i>true</i> , if the edge (c,i,j) belongs to the 2D complex.
<i>bool</i>	<i>c2t3.is_in_complex(Vertex_handle v)</i>	Returns <i>true</i> , if the vertex v belongs to the 2D complex.
<i>bool</i>	<i>c2t3.is_regular_or_boundary_for_vertices(Vertex_handle v)</i>	Returns <i>true</i> if the status of vertex v is <i>REGULAR</i> or <i>BOUNDARY</i> . <i>Precondition:</i> All the edges of the complex incident to v are <i>REGULAR</i> or <i>BOUNDARY</i> .

Traversal of the complex

The data structure provides iterators to visit the facets, edges and vertices of the complex. All those iterators are bidirectional and non mutable.

<i>Facet_iterator</i>	<i>c2t3.facets_begin()</i>	Returns an iterator with value type <i>Facet</i> to visit the facets of the 2D complex.
<i>Facet_iterator</i>	<i>c2t3.facets_end()</i>	Returns the past the end iterator for the above iterator.
<i>Edge_iterator</i>	<i>c2t3.edges_begin()</i>	Returns an iterator with value type <i>Edge</i> to visit the edges of the 2D complex which are not isolated.
<i>Edge_iterator</i>	<i>c2t3.edges_end()</i>	Returns the past the end iterator for the above iterator.
<i>Boundary_edges_iterator</i>	<i>c2t3.boundary_edges_begin()</i>	Returns an iterator with value type <i>Edge</i> to visit the boundary edges of the complex.
<i>Boundary_edges_iterator</i>	<i>c2t3.boundary_edges_end()</i>	Returns the past the end iterator for the above iterator.
<i>Vertex_iterator</i>	<i>c2t3.vertices_begin()</i>	Returns an iterator with value type <i>Vertex_handle</i> to visit the vertices of the 2D complex.
<i>Vertex_iterator</i>	<i>c2t3.vertices_end()</i>	Returns the past the end iterator for the above iterator.

template <class OutputIterator>

OutputIterator *c2t3.incident_facets(Vertex_handle v, OutputIterator facets)*

Copies the *Facets* of the complex incident to *v* to the output iterator *facets*. Returns the resulting output iterator.

Precondition: *c2t3.triangulation().dimension() = 3*, *v* \neq *Vertex_handle()*, *c2t3.triangulation().is_vertex(v)*.

The following function is the basic function to walk on the 2D complex

Facet *c2t3.neighbor(Facet f, int j)*

Returns the facet of the complex which is the neighbor of the facet *f* opposite to the vertex with index *j* of *f*. The vertices of the facet *f = (cell c, i)* are numbered (0,1,2) (according to the *vertex_triple_index(i,j)* member function of *Triangulation_3*) in such a way that facet *f* is oriented by the outward normal of tetraedra *c*. If there is no such neighbor, or if the edge is singular the functions returns *Facet()*.

Facet *c2t3.neighbor(Cell_handle c, int i, int j)*

Returns the facet of the complex which is the neighbor of the facet *f* opposite to the vertex with index *j* of *f*. See above.

make_surface_mesh.

SurfaceMeshFacetsCriteria_3

Definition

The Delaunay refinement process involved in the function template *make_surface_mesh* is guided by a set of refinement criteria. The concept `SurfaceMeshFacetsCriteria_3` describes the type which handles those criteria. It corresponds to the requirements for the template parameter *FacetsCriteria* of the surface mesher function *make_surface_mesh*<*SurfaceMeshC2T3*,*Surface*,*FacetsCriteria*,*Tag*> .

Typically the meshing criteria are a set of elementary criteria, each of which has to be met by the facets of the final mesh. The meshing algorithm eliminates in turn *bad* facets, i.e., facets that do not meet all the criteria.

The size and quality of the final mesh depends on the order according to which bad facets are handled. Therefore, the meshing algorithm needs to be able to quantify the facet qualities and to compare the qualities of different faces. The concept `SurfaceMeshFacetsCriteria_3` defines a type *Quality* designed to measure the quality of a mesh facet. Typically this quality is a multicomponent variable. Each component corresponds to one criterion and measures how much the facet deviates from meeting this criterion. Then, the comparison operator on qualities is just a lexicographical comparison. The meshing algorithm handles facets with lowest quality first. The qualities are computed by a function *is_bad*(*Facet* *f*, *Quality*& *q*).

Types

SurfaceMeshFacetsCriteria_3::Facet

The type of facets. This type has to match the *Facet* type in the triangulation type used by the mesher function. (This triangulation type is the type *SurfaceMeshC2T3::Triangulation* provided by the model of *SurfaceMeshComplex_2InTriangulation_3* plugged as first template parameter of *make_surface_mesh*).

SurfaceMeshFacetsCriteria_3::Quality

Default constructible, copy constructible, assignable, and less-than comparable type.

Operations

bool *criteria.is_bad*(*Facet* *f*, *Quality*& *q*)

Assigns the quality of the facet *f* to *q*, and returns *true* if *f* does not meet the criteria.

CGAL::Surface_mesh_default_criteria_3<Tr>

Definition

The class *Surface_mesh_default_criteria_3<Tr>* implements the most commonly used combination of meshing criteria. It involves mainly three criteria which are in order:

- a lower bound on the minimum angle in degrees of the surface mesh facets.
- an upper bound on the radius of surface Delaunay balls. A surface Delaunay ball is a ball circumscribing a facet, centered on the surface and empty of vertices. Such a ball exists for each facet of the current surface mesh. Indeed the current surface mesh is the Delaunay triangulation of the current sampling restricted to the surface which is just the set of facets in the three dimensional Delaunay triangulation of the sampling that have a Delaunay surface ball.
- an upper bound on the center-center distances of the surface mesh facets. The center-center distance of a surface mesh facet is the distance between the facet circumcenter and the center of its surface Delaunay ball.

```
#include <CGAL/Surface_mesh_default_criteria_3.h>
```

SurfaceMeshTraits_3

Definition

The concept `SurfaceMeshTraits_3` describes the knowledge that is required on the surface to be meshed. A model of this concept implements an oracle that is able to tell whether a segment (or a ray, or a line) intersects the surface or not and to compute some intersection points if any. The concept `SurfaceMeshTraits_3` also includes a constructor able to provide a small set of initial points on the surface.

Types

<code>SurfaceMeshTraits_3:: Point_3</code>	The type of points. This type is required to match the point type of the three dimensional embedding triangulation <code>C2T3::Triangulation_3</code> .
<code>SurfaceMeshTraits_3:: Segment_3</code>	The type of segments.
<code>SurfaceMeshTraits_3:: Ray_3</code>	The type of rays.
<code>SurfaceMeshTraits_3:: Line_3</code>	The type of lines.
<code>SurfaceMeshTraits_3:: Surface_3</code>	The surface type.

`SurfaceMeshTraits_3:: Intersect_3`

A model of this type provides the operator `CGAL::Object operator()(Surface_3 surface, Type1 type1)` to compute the intersection of the surface with an object of type `Type1` which may be `Segment_3`, `Ray_3` or `Line_3`.

`SurfaceMeshTraits_3:: Construct_initial_points`

A model of this type provides the following operators to construct initial points on the surface:

```
template <class OutputIteratorPoints>
OutputIteratorPoints operator()(OutputIteratorPoints pts)
which outputs a set of points on the surface,
template <class OutputIteratorPoints>
OutputIteratorPoints operator() (OutputIteratorPoints pts,
int n)
which outputs a set of n points on the surface.
```

Operations

The following functions give access to the construction objects:

```
Intersect_3          traits.intersect_3_object()
Construct_initial_points
                    traits.construct_initial_points_object()
```

`Surface_mesh_traits_generator_3<Surface>::Type`

See Also

make_surface_mesh

CGAL::Surface_mesh_traits_generator_3<Surface>

Definition

The class *Surface_mesh_traits_generator_3<Surface>* provides a type *Type*, that is a model of the concept *SurfaceMeshTraits_3* for the surface type *Surface*.

The type *Surface* is required to be a model of the concept *Surface_3*, which means that it is copy constructible and assignable. In addition, a *Surface* type is required

- either to provide a nested type *Surface::Surface_mesher_traits_3* that is a model of *SurfaceMeshTraits_3*
- or to be a surface type for which a specialization of the traits generator *Surface_mesh_traits_generator_3<Surface>* exists.

Currently, the library provides partial specializations of the traits generator for implicit surfaces (*Implicit_surface_3<Traits, Function>*) and gray level images (*Gray_level_image_3<FT, Point>*).

```
#include <CGAL/Surface_mesh_traits_generator_3.h>
```

```
Surface_mesh_traits_generator_3<Surface>:: Type
```

A model of the concept *SurfaceMeshTraits_3*.

SurfaceMeshTriangulation_3

Definition

The concept `SurfaceMeshTriangulation_3` describes the triangulation type used by the surface mesher *make_surface_mesh* to represent the three dimensional triangulation embedding the surface mesh. Thus, this concept describes the requirements for the triangulation type `SurfaceMeshC2T3::Triangulation` nested in the model of `SurfaceMeshComplex2InTriangulation3` plugged as the template parameter `SurfaceMeshC2T3` of *make_surface_mesh*. It also describes the requirements for the triangulation type plugged in the class `Surface_mesh_complex_2_in_triangulation_3<Tr>`.

Types

`SurfaceMeshTriangulation_3::Point` The point type. It must be `DefaultConstructible`, `CopyConstructible` and `Assignable`.

Vertices and *cells* of the triangulation are manipulated via handles, which support the two dereference operators *operator** and *operator->*.

`SurfaceMeshTriangulation_3::Vertex_handle` Handle to a data representing a *vertex*. *Vertex_handle* must be a model of *Handle* and its *value type* must be model of `TriangulationDataStructure_3::Vertex`.

`SurfaceMeshTriangulation_3::Cell_handle` Handle to a data representing a *cell*. *Cell_handle* must be a model of *Handle* and its *value type* must be model of `TriangulationDataStructure_3::Cell`.

`typedef CGAL::Triple<Cell_handle, int, int>`

Edge; The edge type.
`typedef std::pair<Cell_handle, int>`

Facet; The facet type.

The following iterators allow one to visit all finite vertices, edges and facets of the triangulation.

`SurfaceMeshTriangulation_3::Finite_vertices_iterator`
 Iterator over finite vertices

`SurfaceMeshTriangulation_3::Finite_edges_iterator`
 Iterator over finite edges

`SurfaceMeshTriangulation_3::Finite_facets_iterator`
 Iterator over finite facets

`SurfaceMeshTriangulation_3::Geom_traits` The geometric traits class. Must be a model of `DelaunayTriangulationTraits_3`.

Creation

<i>SurfaceMeshTriangulation_3</i> <i>t</i> ;	default constructor.
<i>SurfaceMeshTriangulation_3</i> <i>t</i> (<i>tr</i>);	Copy constructor. All vertices and faces are duplicated.

Assignment

<i>SurfaceMeshTriangulation_3</i> & <i>t</i> = <i>tr</i>	The triangulation <i>tr</i> is duplicated, and modifying the copy after the duplication does not modify the original. The previous triangulation held by <i>t</i> is deleted.
<i>void</i> <i>t.clear</i> ()	Deletes all finite vertices and all cells of <i>t</i> .

Access Functions

<i>int</i> <i>t.dimension</i> ()	Returns the dimension of the affine hull.
<i>DelaunayTriangulationTraits_3</i> <i>t.geom_traits</i> ()	Returns a const reference to a model of <i>DelaunayTriangulationTraits_3</i> .

Voronoi diagram

<i>Object</i> <i>t.dual</i> (<i>Facet</i> <i>f</i>)	Returns the dual of facet <i>f</i> , which is in dimension 3: either a segment, if the two cells incident to <i>f</i> are finite, or a ray, if one of them is infinite; in dimension 2: a point.
---	--

Queries

A point *p* is said to be in conflict with a cell *c* in dimension 3 (resp. a facet *f* in dimension 2) iff *t.side_of_sphere*(*c*, *p*) (resp. *t.side_of_circle*(*f*, *p*)) returns *ON_BOUNDED_SIDE*. The set of cells (resp. facets in dimension 2) which are in conflict with *p* is connected, and it forms a hole.

template <*class* *OutputIteratorBoundaryFacets*, *class* *OutputIteratorCells*, *class* *OutputIteratorInternalFacets*>

Triple<*OutputIteratorBoundaryFacets*, *OutputIteratorCells*, *OutputIteratorInternalFacets*>

t.find_conflicts(*Point* *p*,
 Cell_handle *c*,
 OutputIteratorBoundaryFacets *bfit*,
 OutputIteratorCells *cit*,

OutputIteratorInternalFacets ifit)

Computes the conflict hole induced by p . The starting cell (resp. facet) c must be in conflict. Then this function returns respectively in the output iterators:

- *cit*: the cells (resp. facets) in conflict.
- *bfit*: the facets (resp. edges) on the boundary, that is, the facets (resp. edges) (t, i) where the cell (resp. facet) t is in conflict, but $t \rightarrow neighbor(i)$ is not.
- *ifit*: the facets (resp. edges) inside the hole, that is, delimiting two cells (resp facets) in conflict.

Returns the *Triple* composed of the resulting output iterators.

The following iterators allow the user to visit facets, edges and vertices of the triangulation.

Finite_vertices_iterator

t.finite_vertices_begin()

Starts at an arbitrary finite vertex. Then ++ and -- will iterate over finite vertices. Returns *finite_vertices_end()* when *t.number_of_vertices()* = 0.

Finite_vertices_iterator

t.finite_vertices_end()

Past-the-end iterator

Finite_edges_iterator

t.finite_edges_begin()

Starts at an arbitrary finite edge. Then ++ and -- will iterate over finite edges. Returns *finite_edges_end()* when *t.dimension()* < 1.

Finite_edges_iterator

t.finite_edges_end()

Past-the-end iterator

Finite_facets_iterator

t.finite_facets_begin()

Starts at an arbitrary finite facet. Then ++ and -- will iterate over finite facets. Returns *finite_facets_end()* when *t.dimension()* < 2.

Finite_facets_iterator

t.finite_facets_end()

Past-the-end iterator

template <class OutputIterator>

OutputIterator *t*.incident_cells(Vertex_handle v, OutputIterator cells)

Copies the *Cell_handles* of all cells incident to v to the output iterator *cells*. If *t.dimension()* < 3, then do nothing. Returns the resulting output iterator.

Precondition: $v \neq \text{Vertex_handle}()$, $t.is_vertex(v)$.

template <class OutputIterator>

OutputIterator *t*.incident_cells(Vertex_handle v, OutputIterator cells)

Copies the *Cell_handles* of all cells incident to v to the output iterator *cells*. If *t.dimension()* < 3, then do nothing. Returns the resulting output iterator.

<i>bool</i>	<i>t.is_vertex(Point p, Vertex_handle & v)</i>	Tests whether <i>p</i> is a vertex of <i>t</i> by locating <i>p</i> in the triangulation. If <i>p</i> is found, the associated vertex <i>v</i> is given.
<i>bool</i>	<i>t.is_edge(Vertex_handle u, Vertex_handle v, Cell_handle & c, int & i, int & j)</i>	Tests whether <i>(u,v)</i> is an edge of <i>t</i> . If the edge is found, it gives a cell <i>c</i> having this edge and the indices <i>i</i> and <i>j</i> of the vertices <i>u</i> and <i>v</i> in <i>c</i> , in this order. <i>Precondition: u and v are vertices of t.</i>
<i>bool</i>	<i>t.is_infinite(const Vertex_handle v)</i>	<i>true</i> , iff vertex <i>v</i> is the infinite vertex.
<i>bool</i>	<i>t.is_infinite(const Cell_handle c)</i>	<i>true</i> , iff <i>c</i> is incident to the infinite vertex. <i>Precondition: t.dimension() = 3.</i>
<i>Facet</i>	<i>t.mirror_facet(Facet f)</i>	Returns the same facet viewed from the other adjacent cell.
<i>int</i>	<i>t.vertex_triple_index(const int i, const int j)</i>	Return the indexes of the <i>j</i> th vertex of the facet of a cell opposite to vertex <i>i</i> .

Point location

<i>Cell_handle</i>	<i>t.locate(Point query, Cell_handle start = Cell_handle())</i>	<p>If the point <i>query</i> lies inside the convex hull of the points, the cell that contains the query in its interior is returned. If <i>query</i> lies on a facet, an edge or on a vertex, one of the cells having <i>query</i> on its boundary is returned.</p> <p>If the point <i>query</i> lies outside the convex hull of the points, an infinite cell with vertices $\{p, q, r, \infty\}$ is returned such that the tetrahedron $(p, q, r, query)$ is positively oriented (the rest of the triangulation lies on the other side of facet (p, q, r)).</p> <p>Note that <i>locate</i> works even in degenerate dimensions: in dimension 2 (resp. 1, 0) the <i>Cell_handle</i> returned is the one that represents the facet (resp. edge, vertex) containing the query point.</p> <p>The optional argument <i>start</i> is used as a starting place for the search.</p>
--------------------	--	--

Cell_handle

```
t.locate( Point query,  
         Locate_type & lt,  
         int & li,  
         int & lj,  
         Cell_handle start = Cell_handle())
```

If *query* lies inside the affine hull of the points, the *k*-face (finite or infinite) that contains *query* in its interior is returned, by means of the cell returned together with *lt*, which is set to the locate type of the query (*VERTEX*, *EDGE*, *FACET*, *CELL*, or *OUTSIDE_CONVEX_HULL* if the cell is infinite and *query* lies strictly in it) and two indices *li* and *lj* that specify the *k*-face of the cell containing *query*.

If the *k*-face is a cell, *li* and *lj* have no meaning; if it is a facet (resp. vertex), *li* gives the index of the facet (resp. vertex) and *lj* has no meaning; if it is an edge, *li* and *lj* give the indices of its vertices.

If the point *query* lies outside the affine hull of the points, which can happen in case of degenerate dimensions, *lt* is set to *OUTSIDE_AFFINE_HULL*, and the cell returned has no meaning. As a particular case, if there is no finite vertex yet in the triangulation, *lt* is set to *OUTSIDE_AFFINE_HULL* and *locate* returns the default constructed handle.

The optional argument *start* is used as a starting place for the search.

template <class CellIt>

Vertex_handle

```
t.insert_in_hole( Point p, CellIt cell_begin, CellIt cell_end, Cell_handle begin, int i)
```

Creates a new vertex by starring a hole. It takes an iterator range [*cell_begin*; *cell_end*] of *Cell_handles* which specifies a hole: a set of connected cells (resp. facets in dimension 2) which is star-shaped wrt *p*. (*begin*, *i*) is a facet (resp. an edge) on the boundary of the hole, that is, *begin* belongs to the set of cells (resp. facets) previously described, and *begin*->*neighbor(i)* does not. Then this function deletes all the cells (resp. facets) describing the hole, creates a new vertex *v*, and for each facet (resp. edge) on the boundary of the hole, creates a new cell (resp. facet) with *v* as vertex. Then *v*->*set_point(p)* is called and *v* is returned.

Precondition: *t.dimension()* ≥ 2 , the set of cells (resp. facets in dimension 2) is connected, its boundary is connected, and *p* lies inside the hole, which is star-shaped wrt *p*.

SurfaceMeshVertexBase_3

Definition

The concept `SurfaceMeshVertexBase_3` describes the vertex base type of the three dimensional triangulation used to embed the surface mesh.

More precisely, the first template parameter `SurfaceMeshC2T3` of the surface mesher `make_surface_mesh` is a model of the concept `SurfaceMeshComplex_2InTriangulation_3` which describes a data structure to store a pure two dimensional complex embedded in a three dimensional triangulation. In particular, the type `SurfaceMeshC2T3` is required to provide a three dimensional triangulation type `SurfaceMeshC2T3::Triangulation_3`. The concept `SurfaceMeshVertexBase_3` describes the vertex base type required in this triangulation type.

Refines

TriangulationVertexBase_3

The surface mesher algorithm issues frequent queries about the status of the vertices with respect to the two dimensional complex that represents the current surface approximation. The class `SurfaceMeshVertexBase_3` offers a caching mechanism to answer more efficiently these queries. The caching mechanism includes two cached integers, which, when they are valid, store respectively the number of complex facets incident to the vertex and the number of connected components of the adjacency graph of those facets.

Creation

Operations

<i>bool</i>	<i>vb.is_c2t3_cache_valid()</i>	Returns <i>true</i> if the cache is valid.
<i>void</i>	<i>vb.invalidate_c2t3_cache()</i>	Invalidates the cache.
<i>int</i>	<i>vb.cached_number_of_incident_facets()</i>	Returns the cached number of facets of the complex incident to the vertex.
<i>int</i>	<i>vb.cached_number_of_components()</i>	This method concerns the adjacency graph of the facets of the complex incident to the vertex and returns a cached value for the number of connected components this graph.

CGAL::output_surface_facets_to_polyhedron

Definition

output_surface_facets_to_polyhedron() converts a surface reconstructed by *make_surface_mesh()* to a *Polyhedron_3<Traits>*.

```
#include <CGAL/IO/output_surface_facets_to_polyhedron.h>
```

```
template<class SurfaceMeshComplex_2InTriangulation_3, class Polyhedron>
bool      output_surface_facets_to_polyhedron( SurfaceMeshComplex_2InTriangulation_3 c2t3,
                                              Polyhedron& output_polyhedron)
```

Gets reconstructed surface out of a *SurfaceMeshComplex_2InTriangulation_3* object.

This variant exports the surface as a polyhedron. It requires the surface to be manifold. For this purpose, you may call *make_surface_mesh()* with *Manifold_tag* or *Manifold_with_boundary_tag* parameter.

Template Parameters:

SurfaceMeshComplex_2InTriangulation_3: model of the *SurfaceMeshComplex_2InTriangulation_3* concept. *Polyhedron*: an instance of *Polyhedron_3<Traits>*.

Returns: true if the surface is manifold and orientable.

Parameters:

c2t3: Input surface. *output_polyhedron*: Output polyhedron.

47.1 Introduction

This CGAL component implements a surface reconstruction method which takes as input point sets with oriented normals and computes an implicit function. We assume that the input points contain no outliers and little noise. The output surface mesh is generated by extracting an isosurface of this function with the CGAL Surface Mesh Generator [RY07] or potentially with any other surface contouring algorithm.

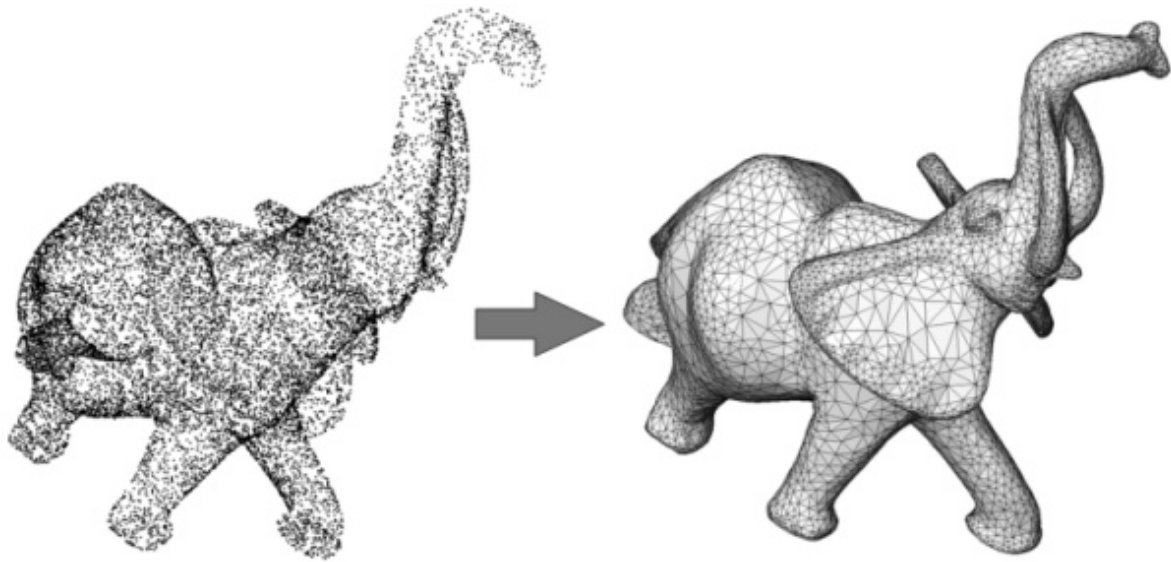

Figure 47.1: Poisson surface reconstruction. Left: 17K points sampled on the statue of an elephant with a Minolta laser scanner. Right: reconstructed surface mesh.

More specifically, the core surface reconstruction algorithm consists of computing an implicit function which is an approximate indicator function of the inferred solid (Poisson Surface Reconstruction - referred to as Poisson). Poisson is a two steps process: it requires solving for the implicit function before function evaluation.

47.2 Common Reconstruction Pipeline

Surface reconstruction from point sets is often a sequential process with the following steps: 1) Scanning and scan alignment produce a set of points or points with normals; 2) Outlier removal; 3) Simplification to reduce the number of input points; 4) Smoothing to reduce noise in the input data; 5) Normal estimation and orientation when the normals are not already provided by the acquisition device; and 6) Surface reconstruction.

CGAL provides algorithms for all steps listed above except alignment.

Chapter *Point_set_processing_3* [56](#) describes algorithms to pre-process the point set before reconstruction with functions devoted to the simplification, outlier removal, smoothing, normal estimation and normal orientation.

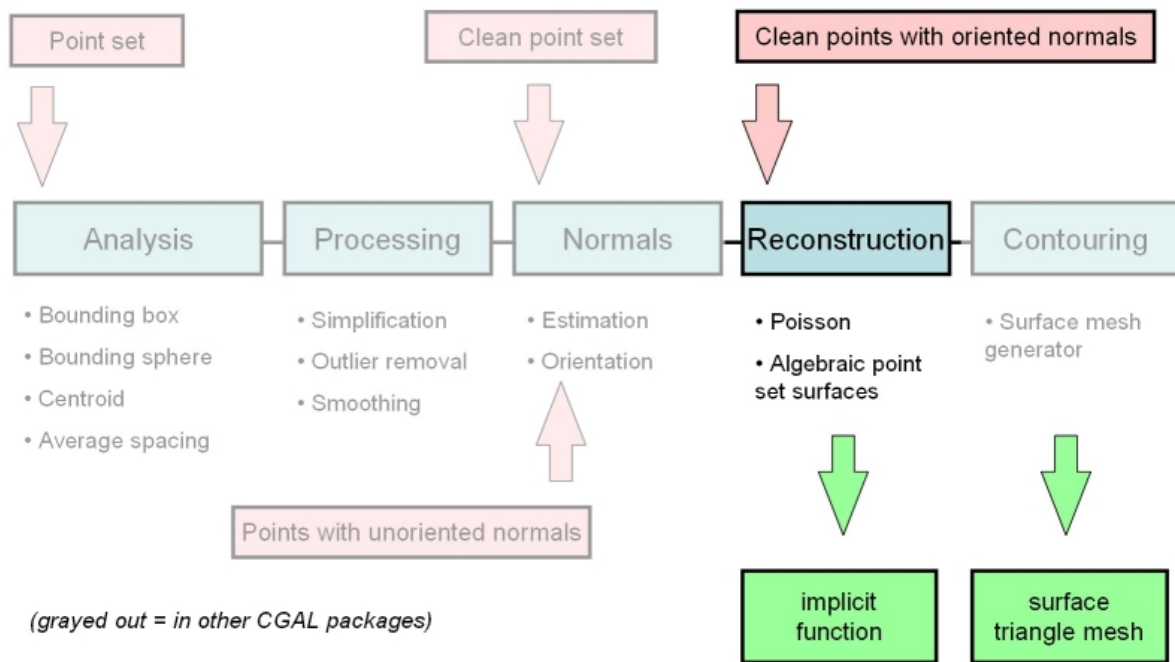

Figure 47.2: Common surface reconstruction pipeline.

47.3 Poisson

Given a set of 3D points with oriented normals (denoted oriented points in the sequel) sampled on the boundary of a 3D solid, the Poisson Surface Reconstruction method [KBH05] solves for an approximate indicator function of the inferred solid, whose gradient best matches the input normals. The output scalar function, represented in an adaptive octree, is then iso-contoured using an adaptive marching cubes.

CGAL implements a variant of this algorithm which solves for a piecewise linear function on a 3D Delaunay triangulation instead of an adaptive octree. The algorithm takes as input a set of 3D oriented points. It builds a 3D Delaunay triangulation from these points and refines it by Delaunay refinement so as to remove all badly shaped (non isotropic) tetrahedra and to tessellate a loose bounding box of the input oriented points. The normal of each Steiner point added during refinement is set to zero. It then solves for a scalar indicator function f represented as a piecewise linear function over the refined triangulation. More specifically, it solves for the Poisson equation $\Delta f = \text{div}(\mathbf{n})$ at each vertex of the triangulation using a sparse linear solver. Eventually, the CGAL surface mesh generator extracts an isosurface with function value set by default to be the median value of f at all input points.

47.3.1 Interface

The class template declaration is:

```

template<
class Gt>
class Poisson_reconstruction_function;

```

with
Gr: Geometric traits class.

Creation:

```
template<typename InputIterator, typename PointPMap, typename NormalPMap>
Poisson_reconstruction_function( InputIterator first,
                                InputIterator beyond,
                                PointPMap point_pmap,
                                NormalPMap normal_pmap)
```

Creates a Poisson implicit function from the [first, beyond) range of points.

Template Parameters:

InputIterator: iterator over input points. *PointPMap*: is a model of *boost::ReadablePropertyMap* with a *value_type* = *Point_3*. It can be omitted if *InputIterator* *value_type* is convertible to *Point_3*. *NormalPMap*: is a model of *boost::ReadablePropertyMap* with a *value_type* = *Vector_3*.

Parameters:

first: iterator over the first input point. *beyond*: past-the-end iterator over the input points. *point_pmap*: property map to access the position of an input point. *normal_pmap*: property map to access the **oriented** normal of an input point.

The main operations are:

<i>Sphere</i>	<i>bounding_sphere()</i>	Returns a sphere bounding the inferred surface.
<i>bool</i>	<i>compute_implicit_function()</i>	

The function *compute_implicit_function()* must be called after each insertion of oriented points. It computes the piecewise linear scalar function operator() by: applying Delaunay refinement, solving for operator() at each vertex of the triangulation with a sparse linear solver, and shifting and orienting operator() such that it is 0 at all input points and negative inside the inferred surface.

Returns false if the linear solver fails.

<i>FT</i>	<i>value(Point p)</i>	Evaluates the implicit function at a given 3D query point.
<i>Point</i>	<i>get_inner_point()</i>	Returns a point located inside the inferred surface.

See details in

CGAL::Poisson_reconstruction_function<GeomTraits>

47.3.2 Example

poisson_reconstruction_example.cpp reads a point set, creates a Poisson implicit function and reconstructs a surface.

File: examples/Surface_reconstruction_points_3/poisson_reconstruction_example.cpp

47.4 Contouring

The computed implicit functions can be iso-contoured to reconstruct a surface by using the CGAL surface mesh generator [RY07, BO05]:

CGAL::make_surface_mesh

The parameter *Tag* affects the behavior of *make_surface_mesh()*:

- *Manifold_tag*: the output mesh is guaranteed to be a manifold surface without boundary.
- *Manifold_with_boundary_tag*: the output mesh is guaranteed to be manifold and may have boundaries.
- *Non_manifold_tag*: the output mesh has no guarantee and hence is outputted as a polygon soup.

47.5 Output

The surface reconstructed by *make_surface_mesh()* is required to be a model of the concept *SurfaceMeshComplex_2InTriangulation_3*, a data structure devised to represent a two dimensional complex embedded into a three dimensional triangulation.

SurfaceMeshComplex_2InTriangulation_3 defines the methods to traverse the reconstructed surface, and e.g. convert it to a triangle soup.

Other CGAL components provide functions to write the reconstructed surface mesh to the Object File Format (OFF) [Phi96] and to convert it to a polyhedron (when it is manifold):

CGAL::output_surface_facets_to_off

CGAL::output_surface_facets_to_polyhedron

See *poisson_reconstruction_example.cpp* example above.

47.6 Case Studies

The surface reconstruction problem being inherently ill-posed, the proposed algorithm does not pretend to reconstruct all kinds of surfaces with arbitrary sampling conditions. This section provides the user with some hints about the ideal sampling and contouring conditions, and depicts some failure cases when these conditions are not matched.

47.6.1 Ideal Conditions

The user must keep in mind that the poisson surface reconstruction algorithm comprises two phases (computing the implicit function from the input point set and contouring an iso-surface of this function). Both require some care in terms of sampling conditions and parameter tuning.

Point Set

Ideally the current implementation of the Poisson surface reconstruction method expects a dense 3D oriented point set (typically matching the epsilon-sampling condition [BO05]) and sampled over a closed, smooth surface. Oriented herein means that all 3D points must come with consistently oriented normals to the inferred surface. Figures 47.3 and 47.4 illustrate cases where these ideal conditions are met.

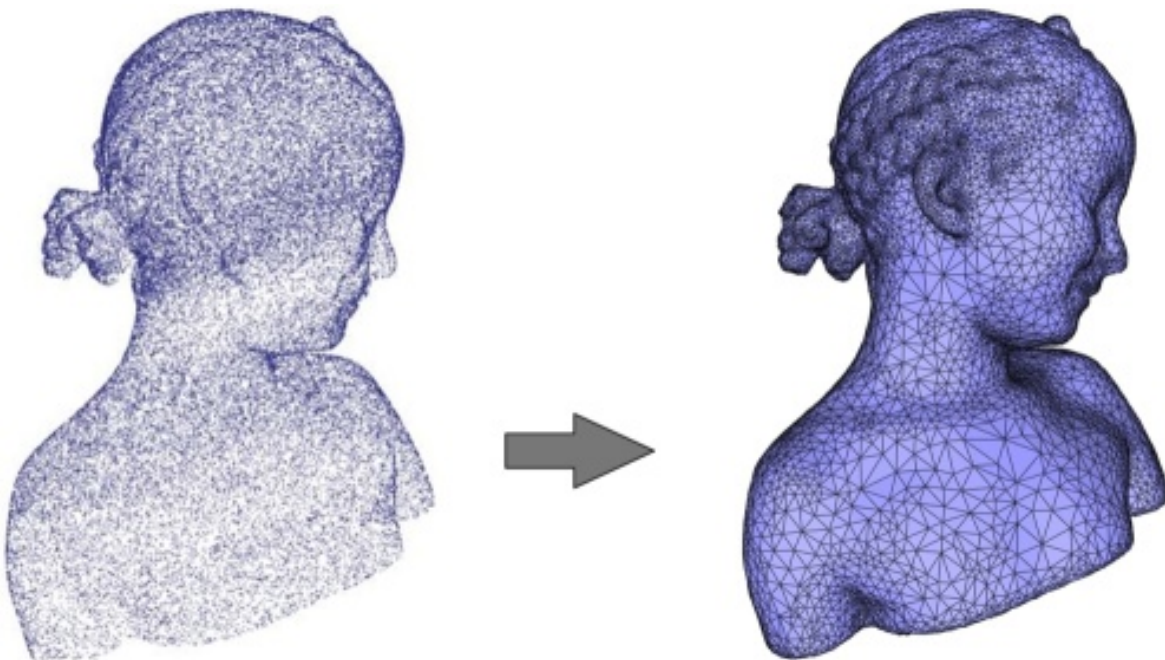

Figure 47.3: Poisson reconstruction. Left: 120K points sampled on a statue (Minolta laser scanner). Right: reconstructed surface mesh.

Figure 47.4: Left: 120K points sampled on a statue (Minolta laser scanner). Right: reconstructed surface mesh.

The algorithm is fairly robust to anisotropic sampling and to noise. It is also robust to missing data through filling the corresponding holes as the algorithm is designed to reconstruct the indicator function of an inferred solid (see Figure 47.5).

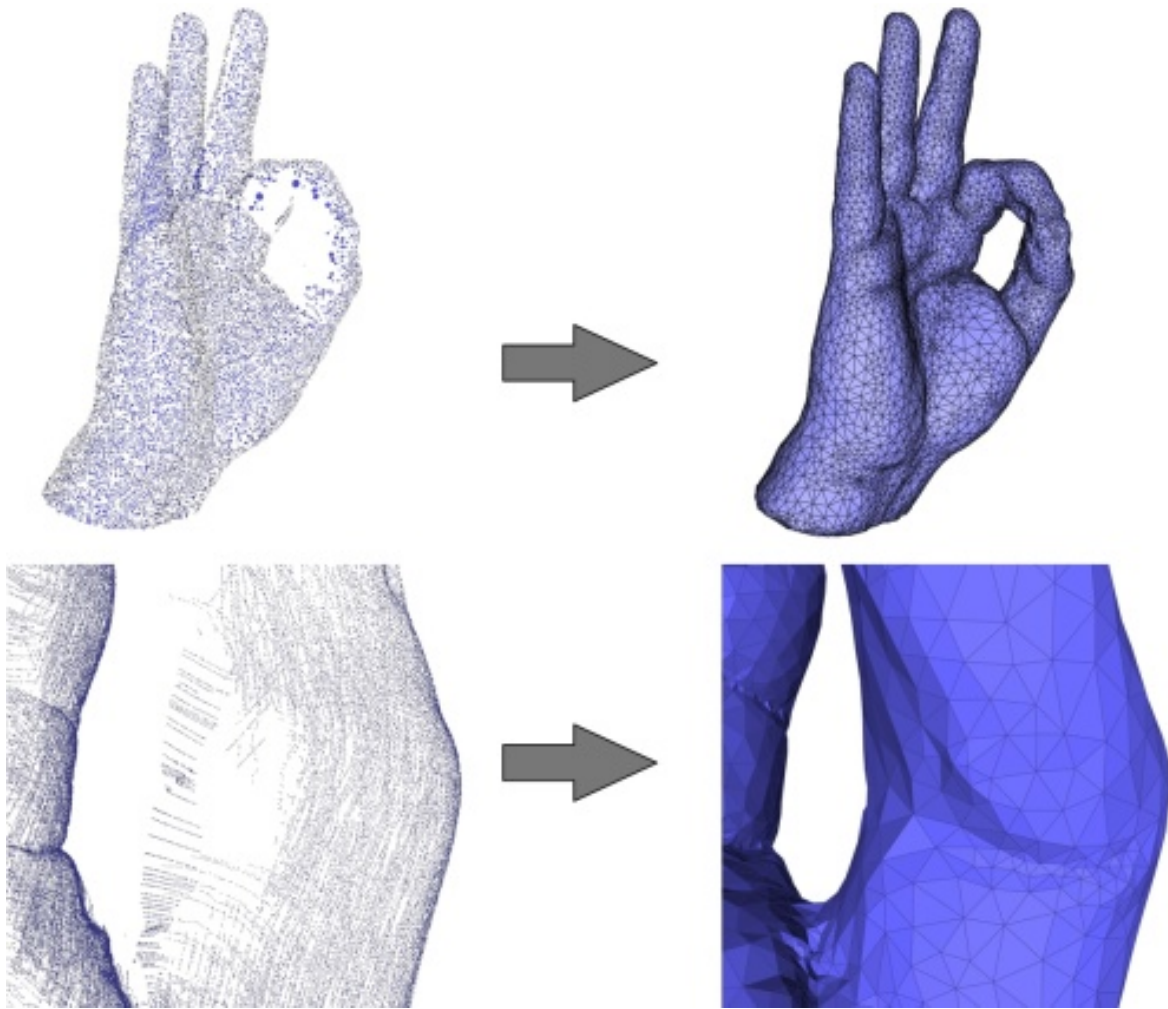

Figure 47.5: Top left: 65K points sampled on a hand (Kreon laser scanner). Bottom left: the point set is highly anisotropic due to the scanning technology. Right: reconstructed surface mesh and closeup. The holes are properly closed.

The algorithm is in general not robust to outliers, although a few outliers do not always create a failure, see Figure 47.6.

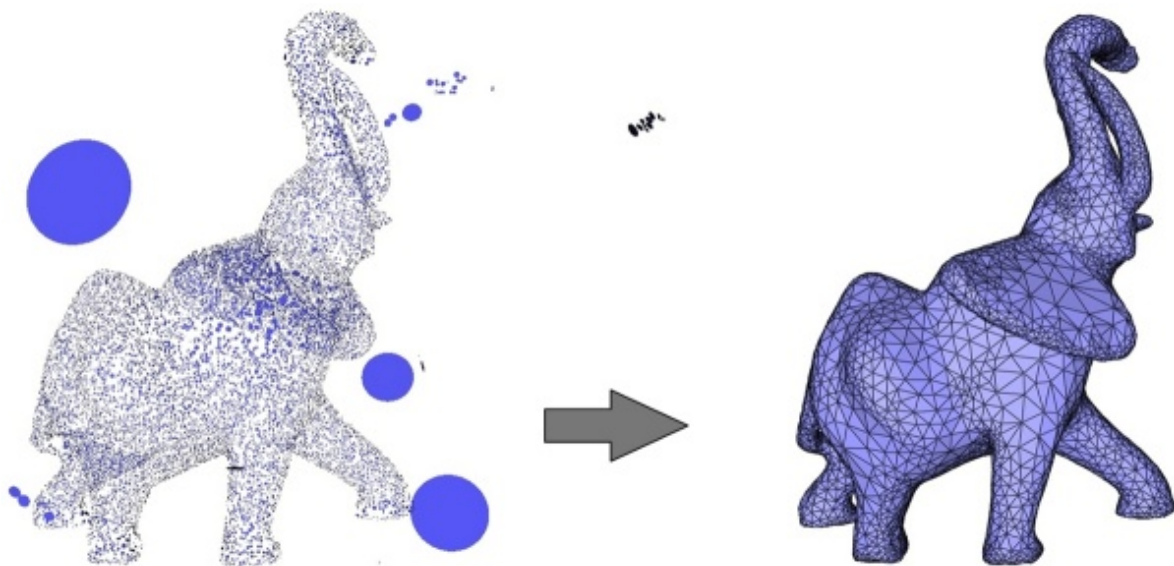

Figure 47.6: Left: 70K points sampled on an elephant with few outliers emphasized with disks. Right: reconstructed surface mesh.

The algorithm works well even when the inferred surface is composed of several connected components, provided that both all normals are properly estimated and oriented (the current CGAL normal orierter algorithm may fail in some cases, see `CGAL::mst_orient_normals()`), and that the final contouring algorithm is properly seeded for each component. When the inferred surface is composed of several nested connected components care should be taken to orient the normals of each component in alternation (inward/outward) so that the final contouring stage picks a proper contouring value.

Contouring Parameters

Our implementation of the Poisson surface reconstruction algorithm computes an implicit function represented as a piecewise linear function over the tetrahedra of a 3D Delaunay triangulation constructed from the input points then refined through Delaunay refinement. For this reason, any iso-surface is also piecewise linear and hence may contain sharp creases. As the contouring algorithm `CGAL::make_surface_mesh()` expects a smooth implicit function these sharp creases may create spurious clusters of vertices in the final reconstructed surface mesh when setting a small mesh sizing or surface approximation error parameter (see Figure 47.7).

One way to avoid these spurious clusters consists of adjusting the mesh sizing and surface approximation parameters large enough compared to the average sampling density (obtained through `CGAL::compute_average_spacing()`) so that the contouring algorithm “perceives” a smooth iso-surface. We recommend to use the following contouring parameters:

- Max triangle radius: at least 100 times the average spacing.
- Approximation distance: at least 0.25 times the average spacing.

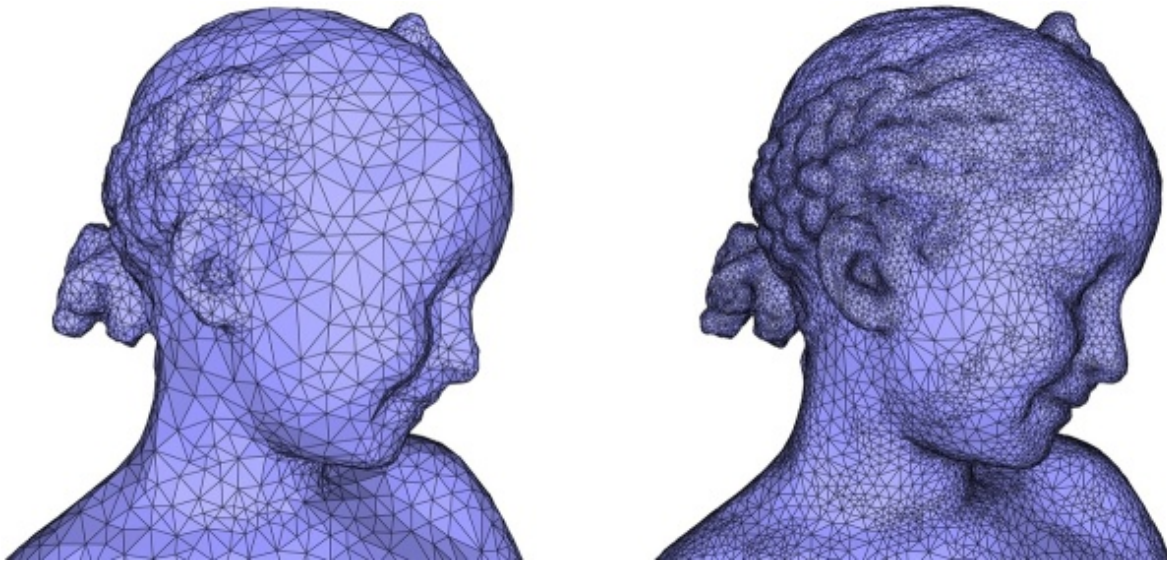

Figure 47.7: Left: surface reconstructed with approximation distance = $0.25 * \text{average spacing}$. Right: surface reconstructed with approximation distance = $0.15 * \text{average spacing}$. Notice the spurious cluster on the chick.

47.6.2 Degraded Conditions

The conditions listed above are rather restrictive and in practice not all of them are met in the applications. We now illustrates the behavior of the algorithm when the conditions are not met in terms of sampling, wrongly oriented normals, noise and sharp creases.

Sparse Sampling

The reconstruction algorithm expects a sufficiently dense point set. Although there is no formal proof of correctness of the algorithm under certain density conditions due to its variational nature, our experiments show that the algorithm reconstructs well all thin features when the local spacing is at most one tenth of the local feature size (the distance to the medial axis, which captures altogether curvature, thickness and separation). When this condition is not met the reconstruction does not reconstruct the thin undersampled features (see Figure 47.8).

Figure 47.8: Left: 50K points sampled on the Neptune trident. The reconstruction (not shown) is successful in this case. Right: point set simplified to 1K points then reconstructed (all input points are depicted with normals). The thin feature is not reconstructed.

Large Holes

The reconstruction is devised to solve for an implicit function which is an approximate indicator function of an inferred solid. For this reason the contouring algorithm always extracts a closed surface mesh and hence is able to fill the small holes where data are missing due, e.g., to occlusions during acquisition. In case of large holes the algorithm still closes them all but sometimes in an unexpected manner. In addition the resulting piecewise linear implicit function may exhibit large triangle patches and sharp creases as the 3D Delaunay triangulation used for solving is very coarse where the holes are filled (see Figure 47.9).

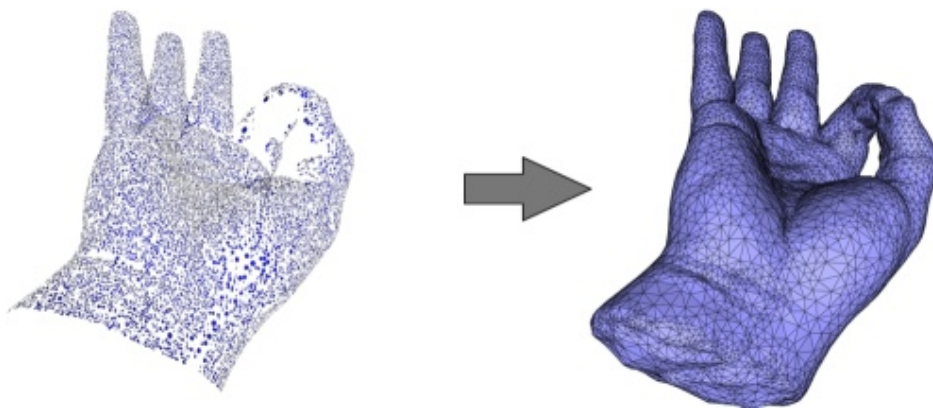

Figure 47.9: Left: 65K points sampled on a hand with no data captured at the wrist base. Right: reconstructed surface mesh. The surface is properly closed on the fingers and also closed at the wrist but in a less plausible manner.

Wrongly Oriented Normals

The Poisson surface reconstruction approaches solves for an implicit function whose gradient best matches a set of input normals. Because it solves this problem in the least squares sense, it is robust to few isolated wrongly oriented (flipped) normals. Nevertheless a cluster of wrongly oriented normals leads to an incorrect implicit function and hence to spurious geometric or even topological distortion (see Figure 47.10).

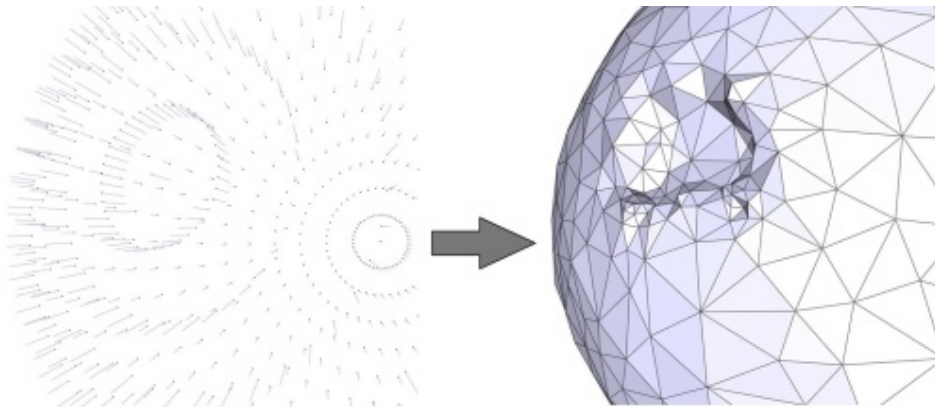

Figure 47.10: Left: points sampled on a sphere with a cluster of wrongly oriented normals. Right: reconstructed surface mesh with a spurious bump.

Noise and Outliers

A large amount of noise inevitably impacts on the reconstruction (see Figure 47.11, top) and the current implementation does not provide any mean to trade data fitting for smoothness. Nevertheless if the signal-to-noise ratio is sufficiently high and/or the surface approximation and sizing parameters set for contouring the iso-surface is large with respect to the noise level the output surface mesh will appear smooth (not shown). If the user wants to produce a smooth and detailed output surface mesh, we recommend to apply smoothing through `CGAL::jet_smooth_point_set()` (see Figure 47.11, bottom).

Figure 47.11: Top-left: points sampled on a sphere and corrupted with a lot of noise. Top-right: reconstructed surface mesh. Bottom-left: smoothed point set. Bottom-right: reconstructed surface mesh.

For a large number of outliers the failure cases (not shown) translate into spurious small connected components and massive distortion near the inferred surface. In this case the outliers must be removed through `CGAL::remove_outliers()`.

Sharp Creases

The current reconstruction algorithm is not able to recover the sharp creases and corners present in the inferred surface. This translates into smoothed sharp creases.

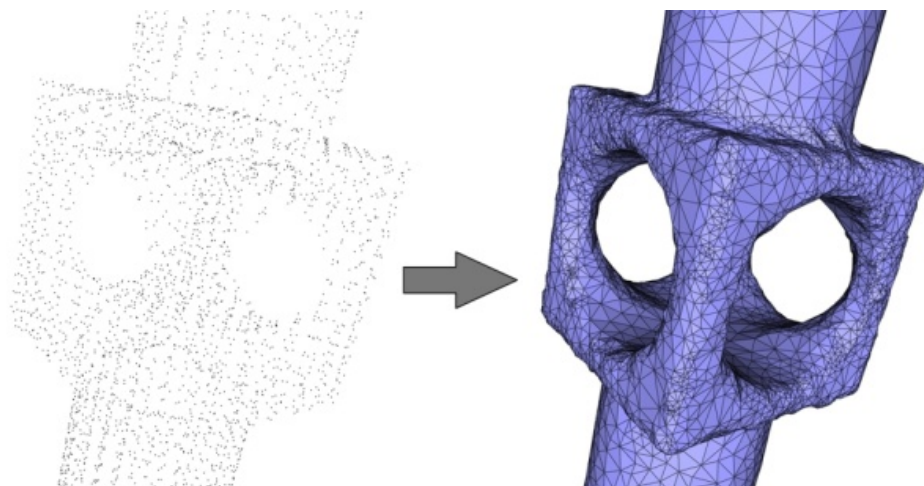

Figure 47.12: Left: 5K points sampled on a mechanical piece with sharp features (creases, darts and corners). Right: reconstructed surface mesh with smoothed creases.

47.7 Performances

We provide some performance numbers for scanning data. We measure the Poisson implicit function computation time, the contouring time for a range of approximation distances, the memory occupancy as well as the influence of the point set simplification. The machine used is a PC running Linux 32 bits with an Intel CPU Core 2 processor clocked at 3 GHz and with 3 GB of RAM. The software is compiled with g++ 4.3.1 compiler with the O3 option which maximizes speed.

47.7.1 Poisson implicit function

The point set chosen for benchmarking the Poisson implicit function is the Bimba con Nastrino point set (1.6 million points) depicted by Figure 47.13. We measure the Poisson implicit function computation (i.e., the call to *Poisson_reconstruction_function::compute_implicit_function()* denoted by Poisson solve hereafter) for this point set as well as for simplified versions obtained through random simplification. The following table provides Poisson solve computation times in seconds for an increasing number of points.

Number of points (x1000)	Poisson solve duration (in s)
60	65
120	137
250	282
500	566
1,000	1,130
1,500	1,777
1,600	1,919

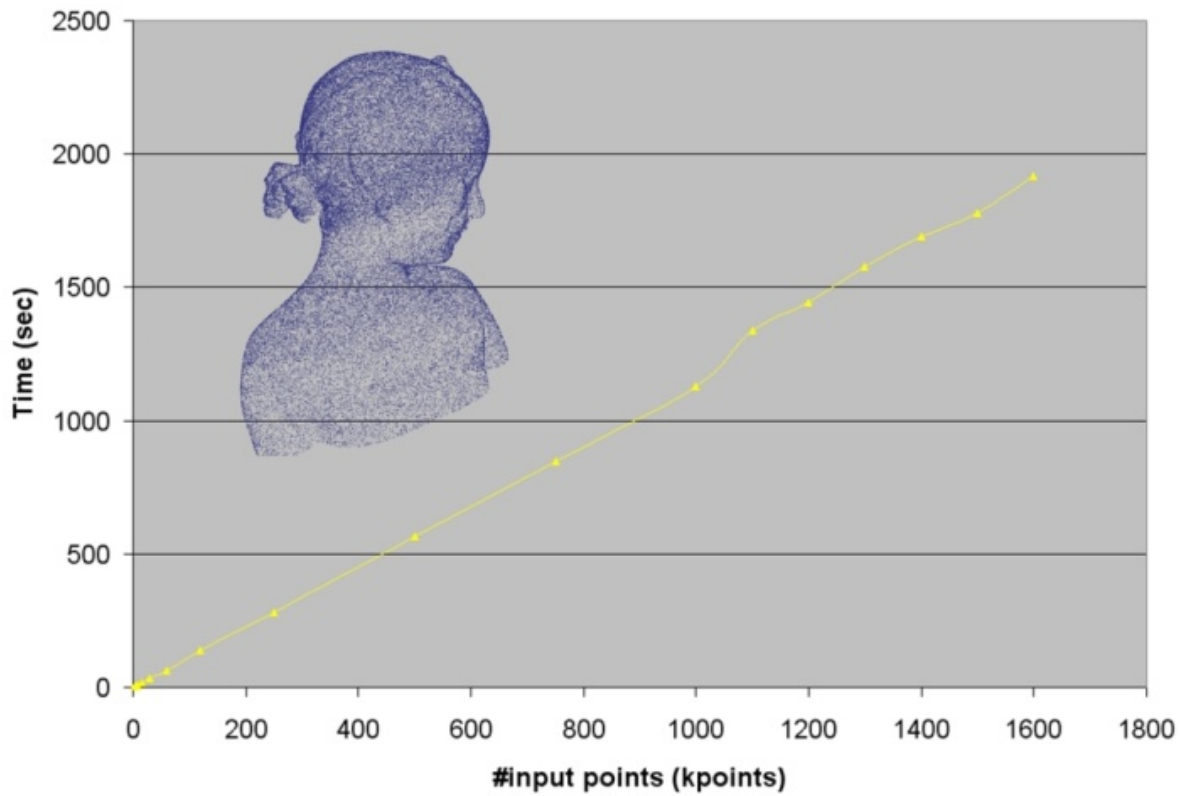

Figure 47.13: Poisson implicit function computation duration (in s) against the number of points for the Bimba con Nastrino point set with 1.6M points (shown) as well as for simplified versions.

47.7.2 Contouring

The point set chosen for benchmarking the contouring stage is the Bimba con Nastrino point set simplified to 120k points. We measure the contouring (i.e. the call to *make_surface_mesh()*) duration and the reconstruction error for a range of approximation distances. The reconstruction error is expressed as the average distance from input points to the reconstructed surface in mm (the Bimba con Nastrino statue is 324 mm tall).

Approx. distance (*average spacing)	Contouring duration (in s)	Reconstruction error (mm)
0.1	177	0.13
0.25	47	0.155
0.5	21	0.23
1	10	0.4
2	5	0.78

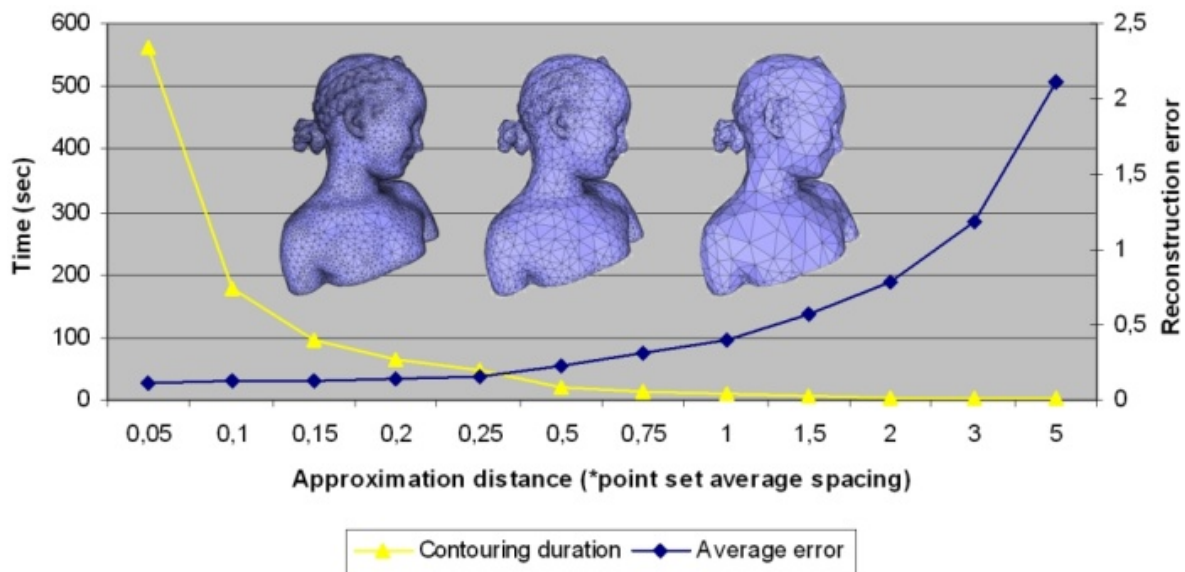

Figure 47.14: Contouring duration (in s) and reconstruction error (mm) against several approximation distance parameters for the Bimba con Nastrino point set simplified to 120k points.

47.7.3 Memory

We measure the memory occupancy for the reconstruction of the full Bimba con Nastrino point set (3.8 millions points) as well as for simplified versions.

The Poisson implicit function computation has a memory peak when solving the Poisson linear system using the TAUCS sparse linear solver. For large point sets, it may fail to allocate big chunks of memory due to memory fragmentation.

The exact limit depends of the allocation scheme used by the compiler. In our experiments, a PC running Linux 32 bits can reconstruct the Bimba con Nastrino point set up to 1.6M points while Windows 32 bits is limited to 1.3M points.

Number of points (x1000)	Memory occupancy (MBytes)
60	330
120	660
250	630
500	980
1000	1570
1200	1939

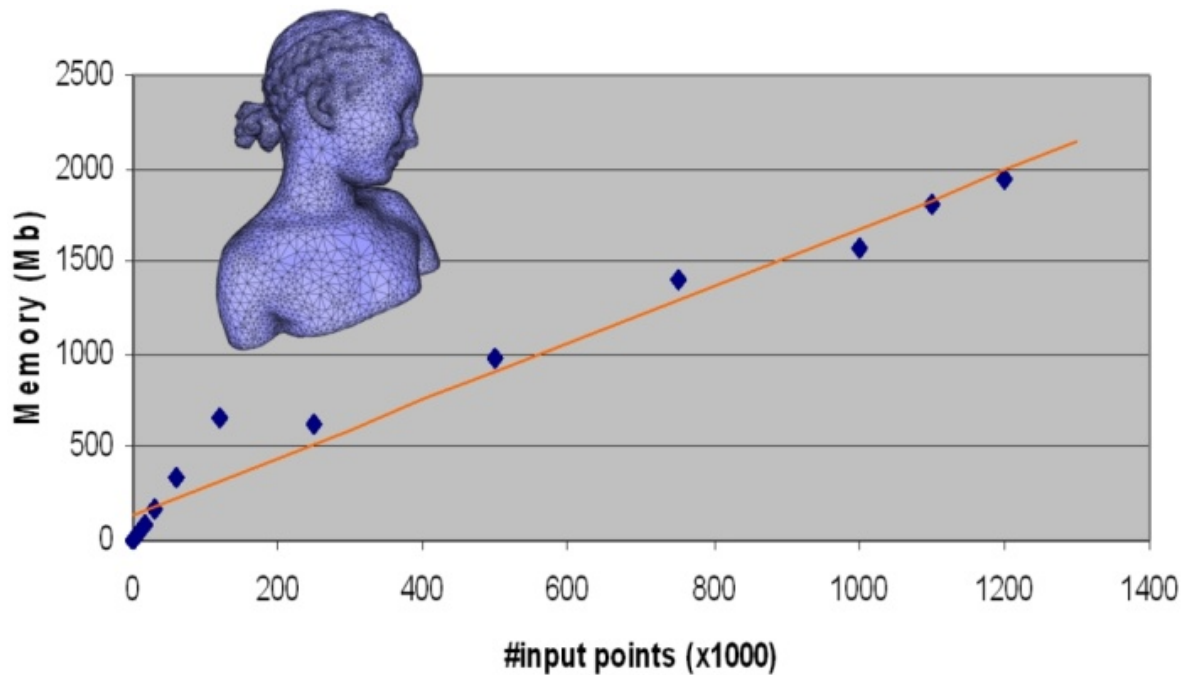

Figure 47.15: Memory occupancy (in MBytes) against number of points for the Bimba con Nastrino point set with 1.2M points as well as for simplified versions. The best fitting line is shown.

47.7.4 Point Set Simplification

Due to the memory limitations described above, we recommend to simplify the point sets captured by laser scanners.

We measure the reconstruction error for the Bimba con Nastrino point set (1.6M points) as well as for simplified versions. All reconstructions use the recommended contouring parameter approximation distance = $0.25 \times$ the input point set's average spacing. The reconstruction error is expressed as the average distance from input points to the reconstructed surface in mm (the Bimba con Nastrino statue is 324 mm tall).

Number of points (x1000)	Reconstruction error (mm)
60	0.27
120	0.15
250	0.11
500	0.079
1,000	0.066
1,500	0.061
1,600	0.06

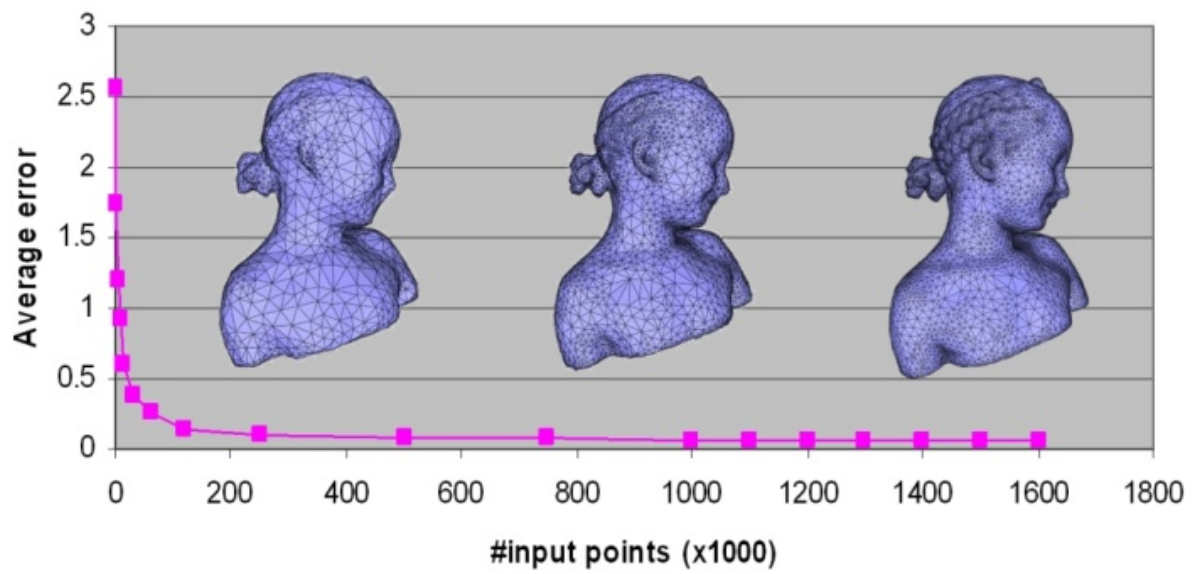

Figure 47.16: Reconstruction error (mm) against number of points for the Bimba con Nastrino point set with 1.6M points as well as for simplified versions.

Surface Reconstruction from Point Sets

Reference Manual

Pierre Alliez, Laurent Saboret, Gael Guennebaud

This CGAL component implements a state-of-the-art surface reconstruction method: Poisson Surface Reconstruction. The input is an unorganized point set, possibly with attributes such as unoriented or oriented normals. The output is either an implicit function (ready for evaluation by any contouring algorithm), or a surface mesh generated by the CGAL surface mesh generator.

Note that since reconstruction methods often require pre-processing a point set (through reduction, smoothing, outlier removal, normal estimation, normal orientation), we provide components devoted to these tasks in the Point Set Processing component.

Creation

```
template<typename InputIterator, typename PointPMap, typename NormalPMap>
Poisson_reconstruction_function<GeomTraits> fct( InputIterator first,
                                                    InputIterator beyond,
                                                    PointPMap point_pmap,
```

NormalPMap normal_pmap)

Creates a Poisson implicit function from the [first, beyond) range of points.

Template Parameters:

InputIterator: iterator over input points. *PointPMap*: is a model of *boost::ReadablePropertyMap* with a *value_type* = *Point_3*. It can be omitted if *InputIterator* *value_type* is convertible to *Point_3*. *NormalPMap*: is a model of *boost::ReadablePropertyMap* with a *value_type* = *Vector_3*.

Parameters:

first: iterator over the first input point. *beyond*: past-the-end iterator over the input points. *point_pmap*: property map to access the position of an input point. *normal_pmap*: property map to access the **oriented** normal of an input point.

Operations

Sphere *fct.bounding_sphere() const* Returns a sphere bounding the inferred surface.
template<class SparseLinearAlgebraTraits_d>
bool *fct.compute_implicit_function(* *SparseLinearAlgebraTraits_d* *solver* *=*
SparseLinearAlgebraTraits_d())

The function *compute_implicit_function()* must be called after the insertion of oriented points. It computes the piecewise linear scalar function operator() by: applying Delaunay refinement, solving for operator() at each vertex of the triangulation with a sparse linear solver, and shifting and orienting operator() such that it is 0 at all input points and negative inside the inferred surface.

Template parameters:

SparseLinearAlgebraTraits_d: Symmetric definite positive sparse linear solver. The default solver is TAUCS Multifrontal Supernodal Cholesky Factorization.

Returns: false if the linear solver fails.

Parameters:

solver: sparse linear solver.

FT *fct.operator()(const Point& p) const*

ImplicitFunction interface: evaluates the implicit function at a given 3D query point.

Point *fct.get_inner_point() const* Returns a point located inside the inferred surface.

Example

See *poisson_reconstruction_example.cpp*.

48.1 Introduction

Skin surfaces, introduced by Edelsbrunner in [Ede99], have a rich and simple combinatorial and geometric structure that makes them suitable for modeling large molecules in biological computing. Meshing such surfaces is often required for further processing of their geometry, like in numerical simulation and visualization.

A skin surface is defined by a set of weighted points (input balls) and a scalar called the shrink factor. If the shrink factor is equal to one, the surface is just the boundary of the union of the input balls. For a shrink factor smaller than one, the skin surface becomes tangent continuous, due to the appearance of patches of spheres and hyperboloids connecting the balls.

This package constructs a mesh isotopic to the skin surface defined by a set of balls and a shrink factor using the algorithm described in [KV05].

An optimized algorithm is implemented for meshing the union of a set of balls.

48.2 Definition of a Skin Surface

This section first briefly reviews skin surfaces. For a more thorough introduction to skin surfaces, we refer to [Ede99] where they were originally introduced.

A skin surface is defined in terms of a finite set of weighted points \mathbf{P} and a shrink factor s , with $0 \leq s \leq 1$. A weighted point $\mathbf{p} = (p, w_p) \in \mathbb{R}^3 \times \mathbb{R}$ corresponds to a ball with center p and radius $\sqrt{w_p}$. A weighted point with zero weight is called an unweighted point.

A pseudo distance between a weighted point $\mathbf{p} = (p, w_p)$ and an unweighted point x is defined as

$$\pi(\mathbf{p}, x) = \|p - x\|^2 - w_p,$$

where $\|p - x\|$ is the Euclidean distance between p and x . The ball corresponding to a weighted point \mathbf{p} is the zero set of $\pi(\mathbf{p}, \cdot)$. Note that if $w_p < 0$ the radius of the ball is imaginary and the zero-set is empty.

We can take convex combinations of weighted points by taking convex combinations of their distance functions. Figure 48.1 (left) shows weighted points that are obtained as convex combinations of the dashed circles. For further reading on the space of circles and spheres we refer to [Ped70].

Starting from a weighted point $\mathbf{p} = (p, w_p)$, the shrunk weighted point \mathbf{p}^s is obtained by taking a convex combination with the unweighted point centered at p , formally $\mathbf{p}^s = s\mathbf{p} + (1 - s)\mathbf{p}'$, with $\mathbf{p}' = (p, 0)$. A simple calculation shows that, $\mathbf{p}^s = (p, s \cdot w_p)$. The set \mathbf{P}^s is the set obtained by shrinking every weighted point of \mathbf{P} by a factor s : $\mathbf{P}^s = \{\mathbf{p}^s \mid \mathbf{p} \in \mathbf{P}\}$. The shrunk weighted points of Figure 48.1 (left) are shown in Figure 48.1 (right).

We now define the skin surface $\text{skn}^s(\mathbf{P})$ associated with a set of weighted points \mathbf{P} . Consider the set of weighted points obtained by taking the convex hull of the input weighted points. A calculation shows that every weighted point lies within the union of the input balls. Next, we shrink each weighted point in the convex hull with the shrink factor s . Hence, we multiply the radius of the corresponding (real) input circles with a factor \sqrt{s} . The skin surface is the boundary of the union of this set of weighted points:

$$\text{skn}^s(\mathbf{P}) = \partial \bigcup \{\mathbf{p}^s \mid \mathbf{p} \in \text{conv}(\mathbf{P})\}. \quad (48.1)$$

Here $\text{conv}(\mathbf{P}) \subset \mathbb{R}^3 \times \mathbb{R}$ is the convex hull of a set of weighted points \mathbf{P} , whereas ∂ denotes the boundary – in \mathbb{R}^3 – of the union of the corresponding set of balls.

Recall that each weighted point in the convex hull of the input weighted points is contained in the union of the input weighted points. Hence, for a shrink factor equal to one, the skin surface is the boundary of the union of the input weighted points.

By definition of a skin surface, the weights of the input balls (their radius-squared) are shrunk with a factor of s and the skin surface wraps around the shrunk input balls. In order to make the skin surface wrap around the (unshrunk) input balls, we can first increase the weights of the input balls by multiplying them with a factor $1/s$ and then compute the skin surface.

48.3 The Interface

The interface to the skin surface package consists of one main function, taking a set of weighted points and a shrink factor and outputting the meshed surface. Further, it defines classes and functions and classed used to perform the main steps of the algorithm. There are two global classes *Skin_surface_3* and *Union_of_balls_3* both of which are models of the concept *SkinSurface_3* and there are two functions to extract a mesh of the skin surface (union of balls) from the objects of the aforementioned classes. A final function takes a mesh and the *Skin_surface_3* (*Union_of_balls_3*) object it is constructed from and refines the mesh. This section describes these classes and functions in more detail.

The main function of the skin surface package takes an iterator range of weighted points, a shrink factor and the number of subdivision steps and outputs a mesh in a *CGAL::Polyhedron_3*:

```
template <class WP_iterator, class Polyhedron_3>
void    make_skin_surface_mesh_3( Polyhedron_3 &p,
                                WP_iterator begin,
                                WP_iterator end,
                                FT shrink_factor=.5,
                                int nSubdiv=0,
                                bool grow_balls = true)
```

Where, *FT* is the number type used by the *Weighted_points*.

To obtain more control over the algorithm, the different steps can also be performed separately. First, a *Skin_surface_3* object is created from an iterator range of weighted points and a shrink factor. Optional arguments are a boolean telling whether the input weighted points should be grown in such a way that the skin surface wraps around the input balls instead of the shrunk input balls.

```
template <class SkinSurfaceTraits_3>
Skin_surface_3( WP_iterator begin, WP_iterator end, FT shrink_factor, bool grow_balls = true)
```

The template parameter should implement the *SkinSurfaceTraits_3* concept. The type *WP_iterator*, is an iterator over weighted points as defined by *SkinSurfaceTraits_3* and *FT* is the number type used by the weighted points.

For a shrink factor equal to one the skin surface is the boundary of the union of the input balls. In this case the algorithm used for meshing the skin surface greatly simplifies. These optimizations are implemented in the class *Union_of_balls_3*. The constructor for the union of balls class is similar, except for the missing shrink factor:

```
template <class SkinSurfaceTraits_3>
    Union_of_balls_3( WP_iterator begin, WP_iterator end, bool grow_balls = true)
```

With a model of the concept *SkinSurface_3* it is possible to generate a coarse mesh isotopic to the skin surface. Using the function *mesh_skin_surface_3* with signature:

```
template <class SkinSurface_3, class Polyhedron>
void    mesh_skin_surface_3( SkinSurface_3 skin_surface, Polyhedron &p)
```

The last function takes the (coarse) mesh and subdivides it in-situ by applying a given number of 1-4 split operations (each triangle is split into four sub-triangles) and moving the new vertices towards the skin surface. If the number of iterations is not specified, one subdivision step is done. The object of the *SkinSurface_3* concept used to construct the coarse mesh is needed to move new points on the skin surface.

```
template <class SkinSurface_3, class Polyhedron >
void    subdivide_skin_surface_mesh_3( SkinSurface_3 skinsurface, Polyhedron &p, int iterations=1)
```

48.4 Timings

The timings of the construction of the coarse mesh and the first subdivision are given in seconds and were done on a Pentium 4, 3.5 GHz, with 1 Gb of memory.

Data set	Number of weighted points	Coarse mesh	first subdivision step
Caffeine	23	0.2 sec.	0.05 sec.
Gramicidin A	318	5 sec.	2 sec.

48.5 Example Programs

48.5.1 Meshing a Skin Surface

The following example shows the construction of a coarse mesh of the skin surface using the function *make_skin_surface_mesh_3*. The output is a *CGAL::Polyhedron*.

```
#include <CGAL/Exact_predicates_inexact_constructions_kernel.h>
#include <CGAL/make_skin_surface_mesh_3.h>
#include <list>

typedef CGAL::Exact_predicates_inexact_constructions_kernel K;
typedef K::Point_3                                     Bare_point;
```

```

typedef CGAL::Weighted_point<Bare_point,K::RT>
    Weighted_point;
typedef CGAL::Polyhedron_3<K>                                Polyhedron;

int main() {
    std::list<Weighted_point> l;
    double                    shrinkfactor = 0.5;

    l.push_front(Weighted_point(Bare_point( 1,-1,-1), 1.25));
    l.push_front(Weighted_point(Bare_point( 1, 1, 1), 1.25));
    l.push_front(Weighted_point(Bare_point(-1, 1,-1), 1.25));
    l.push_front(Weighted_point(Bare_point(-1,-1, 1), 1.25));

    Polyhedron p;

    CGAL::make_skin_surface_mesh_3(p, l.begin(), l.end(), shrinkfactor);

    return 0;
}

```

File: examples/Skin_surface_3/skin_surface_simple.cpp

48.5.2 Meshing and Subdividing a Skin Surface

The following example shows the construction of mesh of the skin surface by explicitly performing different steps of the algorithm. It first constructs a *Skin_surface_3* object from an iterator range of weighted points and a shrink factor. From this object, the coarse mesh isotopic to the skin surface is extracted using the function *CGAL::mesh_skin_surface_3*

Next, the coarse mesh is refined to obtain a better approximation. The use of *CGAL::Skin_surface_polyhedral_items_3<Skin_surface_3>* in the *CGAL::Polyhedron* is not necessary, but gives the subdivision a significant speedup.

```

#include <CGAL/Exact_predicates_inexact_constructions_kernel.h>
#include <CGAL/Skin_surface_3.h>
#include <CGAL/Polyhedron_3.h>
#include <CGAL/mesh_skin_surface_3.h>
#include <CGAL/subdivide_skin_surface_mesh_3.h>
#include "skin_surface_writer.h"
#include <list>
#include <fstream>

typedef CGAL::Exact_predicates_inexact_constructions_kernel K;
typedef CGAL::Skin_surface_traits_3<K>                        Traits;
typedef CGAL::Skin_surface_3<Traits>                          Skin_surface_3;
typedef Skin_surface_3::FT                                     FT;
typedef Skin_surface_3::Weighted_point                        Weighted_point;
typedef Weighted_point::Point                                 Bare_point;
typedef CGAL::Polyhedron_3<K,
    CGAL::Skin_surface_polyhedral_items_3<Skin_surface_3> > Polyhedron;

```

```

int main() {
    std::list<Weighted_point> l;
    FT shrinkfactor = 0.5;

    l.push_front(Weighted_point(Bare_point( 1,-1,-1), 1.25));
    l.push_front(Weighted_point(Bare_point( 1, 1, 1), 1.25));
    l.push_front(Weighted_point(Bare_point(-1, 1,-1), 1.25));
    l.push_front(Weighted_point(Bare_point(-1,-1, 1), 1.25));

    Polyhedron p;

    Skin_surface_3 skin_surface(l.begin(), l.end(), shrinkfactor);
    CGAL::mesh_skin_surface_3(skin_surface, p);

    CGAL::subdivide_skin_surface_mesh_3(skin_surface, p);

    std::ofstream out("mesh.off");
    out << p;

    return 0;
}

```

File: examples/Skin_surface_3/skin_surface_subdiv.cpp

3D Skin Surface Meshing Reference Manual

Nico Kruithof

Skin surfaces form a class of tangent continuous surfaces defined by a set of balls and a scalar called the shrink factor. The skin surface package constructs an triangular mesh isotopic to the skin surface, using the algorithm described in [KV05]. The mesh is stored in a *CGAL::Polyhedron_3*.

SkinSurface_3

Definition

The concept `SkinSurface_3` defines a skin surface and provides an interface for the dedicated skin surface mesher. The concept requires a constructor from an iterator range of weighted points and a shrink factor. By default the input balls are grown in such that the skin surface wraps around the input balls.

Has Models

`CGAL::Skin_surface_3<SkinSurfaceTraits_3>`
`CGAL::Union_of_balls_3<SkinSurfaceTraits_3>`

Types

<code>SkinSurface_3:: Geometric_traits</code>	The geometric traits used for the construction of the regular triangulation.
<code>SkinSurface_3:: Weighted_point</code>	The <code>Weighted_point</code> type defined by the <code>Geometric_traits</code> .
<code>SkinSurface_3:: Bare_point</code>	The <code>Bare_point</code> type defined by the <code>Geometric_traits</code> .
<code>SkinSurface_3:: FT</code>	The <code>FT</code> type defined by the <code>Geometric_traits</code> . This is the number type used by the weighted points.

Creation

`SkinSurface_3 skin(WP_iterator begin, WP_iterator end, RT shrink_factor);`

The mandatory arguments to the constructor are an iterator range `[begin,end)` of weighted points and a shrink factor between 0 and 1.

Operations

`template <class Polyhedron_3>`
`void skin.mesh_skin_surface_3(Polyhedron_3 &p)`

Constructs a coarse mesh in `p`.
Precondition: `Polyhedron_3::HDS` can be used as the template argument of the `Polyhedron_incremental_builder_3<HDS>`.

`template <class Polyhedron_3>`
`void skin.subdivide_skin_surface_mesh_3(Polyhedron_3 &p, int nSubdiv = 1)`

Subdivides the skin surface using `nSubdiv` 1-4 split operations (each triangle is split into four sub-triangles) and the new vertices are moved towards the skin surface.

Refines

Types

SkinSurfaceTraits_3::Construct_anchor_point_3

Creation

constructor that takes the shrink factor as argument. For meshing the boundary of the union of a set of balls, the shrink factor is discarded.

Has Models

CGAL::Skin_surface_traits_3<K> page 2937

Operations

The following functions give access to the constructor objects:

<i>Regular_RT</i>	<i>traits.shrink_factor()</i>	Returns the shrink factor.
-------------------	-------------------------------	----------------------------

Construct_anchor_point_3 traits.construct_anchor_point_3_object()

returns a *Construct_anchor_point_3* object.

CGAL::Skin_surface_3<SkinSurfaceTraits_3>

Definition

The *Skin_surface_3<SkinSurfaceTraits_3>* is the main class in the *Skin_surface_3* package. It is a model of the concept *SkinSurface_3*.

The template argument is required to be a model of the concept *SkinSurfaceTraits_3*, which means that it provides predicates to construct a regular triangulation of the weighted points and for point location in the mixed complex.

```
#include <CGAL/Skin_surface_3.h>
```

Is Model for the Concepts

SkinSurface_3

CGAL::Union_of_balls_3<SkinSurfaceTraits_3>

Definition

The *Union_of_balls_3<SkinSurfaceTraits_3>* is used to represent a skin surface with shrink factor equal to one, which is the boundary of the union of the input balls. This case is handled separately since the mixed complex is equal to the power diagram, which has a much simpler structure.

The template argument must be a model of the concept *SkinSurfaceTraits_3*, which means that it provides the predicates to construct a regular triangulation of the weighted points.

```
#include <CGAL/Union_of_balls_3.h>
```

Is Model for the Concepts

SkinSurface_3

CGAL::Skin_surface_traits_3<K>

Definition

The class *Skin_surface_traits_3<K>* is designed as a default traits class for the class *Skin_surface_3<SkinSurfaceTraits_3>*. It is a model of the *SkinSurfaceTraits_3*.

The template argument *K* must be a model of the *Kernel* concept.

```
#include <CGAL/Skin_surface_traits_3.h>
```

Is Model for the Concepts

SkinSurfaceTraits_3

CGAL::make_skin_surface_mesh_3<Polyhedron_3>

Definition

The function *make_skin_surface_mesh_3<Polyhedron_3>* constructs a mesh isotopic to the skin surface based on the algorithm in [KV05]. It takes as input a range of weighted points and a shrink factor and outputs the mesh in a *Polyhedron_3* object. A number of subdivision steps might be applied to refine the mesh.

```
#include <CGAL/make_skin_surface_mesh_3.h>
```

```
void    mesh_skin_surface_3<Polyhedron_3>( Polyhedron_3 &p,
                                           WP_iterator begin,
                                           WP_iterator end,
                                           double shrink_factor=.5,
                                           int nSubdivisions=0,
                                           bool grow_balls=true)
```

Constructs a mesh of the skin surface defined by the weighted points and the shrink factor.

Precondition: *Polyhedron_3::HDS* can be used as the template argument of the *Polyhedron_incremental_builder_3<HDS>*.

CGAL::mesh_skin_surface_3<SkinSurface_3, Polyhedron_3>

Definition

The function *mesh_skin_surface_3*<*SkinSurface_3*, *Polyhedron_3*> constructs a mesh isotopic to the skin surface based on the algorithm in [KV05]. It takes as input a *SkinSurface_3* object, which is a model of the *SkinSurface_3* concept and outputs the mesh in a *Polyhedron_3* object.

```
#include <CGAL/mesh_skin_surface_3.h>
```

```
void    make_skin_surface_mesh_3<SkinSurface_3,Polyhedron_3>( SkinSurface_3 skin_surface,
                                                                Polyhedron_3 &p)
```

Constructs a mesh of the *skin_surface* in *p*.

Precondition: *SkinSurface_3* is a model of the concept *SkinSurface_3* and *Polyhedron_3::HDS* can be used as the template argument of the *Polyhedron_incremental_builder_3*<*HDS*>.

CGAL::subdivide_skin_surface_mesh_3<SkinSurface_3, Polyhedron_3>

Definition

The function *subdivide_skin_surface_mesh_3*<*SkinSurface_3*, *Polyhedron_3*> subdivides a skin surface mesh constructed by the function *mesh_skin_surface_3*<*SkinSurface_3*, *Polyhedron_3*>.

```
#include <CGAL/subdivide_skin_surface_mesh_3.h>
```

```
void    subdivide_skin_surface_mesh_3<SkinSurface_3,Polyhedron_3>( SkinSurface_3 skin_surface,
                                                                    Polyhedron_3 &p,
                                                                    int nSubdiv = 1)
```

Subdivides the skin surface using *nSubdiv* 1-4 split operations (each triangle is split into four sub-triangles) and the new vertices are moved towards the skin surface.

49.1 Introduction

This package is devoted to the generation of isotropic tetrahedron meshes discretizing 3D domains. The main entry points of this component are two global functions that respectively generate and refine such meshes. The domain to be discretized may be formed either by a single connected component or by several connected components. We refer to the domain as a multi-domain when the different components need to be identified as different subdomains. The mesh generator generates at once a simplicial 3D mesh which includes one submesh for each subdomain and surface meshes which approximate the boundaries of the domain and subdomains.

Input domain

More specifically, the domain to be discretized is assumed to be representable as a pure 3D complex. A 3D complex is a set of faces with dimension 0 (vertices), 1 (edges), 2 (facets) and 3 (cells) such that all faces are pairwise interior disjoint, and the boundary of each face of the complex is the union of faces of the complex. The 3D complex is pure, meaning that each face is included in a face of dimension 3, so that the complex is entirely

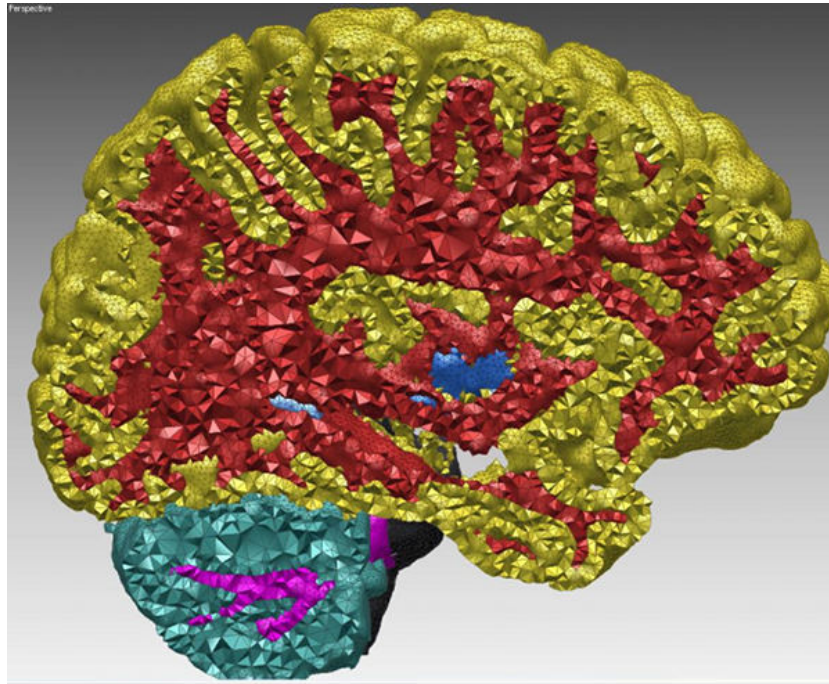

Figure 49.1: Cut-view of a multi-domain 3D mesh generated from a segmented image.

described as a set of 3D cells. The set of faces with dimension lower or equal than 2 form a 2D subcomplex. In the rest of the documentation, we will refer to the input 3D complex as to the input domain.

Note that the input complex faces are not required to be linear. Facets, for instance, are typically smooth surface patches, or portion of surface meshes with boundaries. The mesh generator provides at the same time a 3D mesh discretizing each of the complex cells and a surface mesh approximating the 2D complex that describes cell boundaries. In its current state the mesh generator does not handle sharp creases in the domain description. This does not mean that the domain to be meshed and its subdomains are required to have smooth boundary surfaces. The domain and subdomains boundaries may be provided as smooth patches joined along sharp edges. However, currently, the mesh generator does not take into account the edge description and hence those edges are not accurately represented by a sequence of mesh edges.

The mesh generator is able to handle multiple junctions where three or more subdomains meet. Consequently the generated surface mesh may be non-manifold as a whole, even if each submesh approximating the boundary of a subdomain is manifold.

The domain is input to the mesh generation function, as a class devised to answer queries about the domain as well as its subdomains. Mainly, this class provides predicates which state if a given query point belongs to the domain or not, and in the affirmative, to which of the subdomains it belongs. The current implementation provides classes to represent domains defined by implicit functions, polyhedral domains and domains defined through 3D labeled images.

Output mesh

The resulting mesh is output as a subcomplex of a 3D triangulation, in a class providing various iterators on mesh elements. The 3D triangulation provides an approximation of the domain, subdomains and their boundaries, according to the restricted Delaunay triangulation paradigm. This means that the domain (resp. each subdomain)

is approximated by the union of the tetrahedral cells whose circumcenters are located inside the domain (resp. inside the subdomain). Each surface patch of the domain or subdomains boundary is approximated by the union of the Delaunay facets whose dual Voronoi edges intersect the surface patch. Such facets are called in the following *surface facets* or *boundary facets*.

Delaunay refinement

The mesh generation algorithm is a Delaunay refinement process followed by an optimization phase. The Delaunay refinement process is driven by criteria concerning either the mesh cells or the surface facets. The refinement process terminates when there are no more mesh cells or surface facets violating the user-specified criteria. The Delaunay refinement eliminates all kind of badly shaped tetrahedra except slivers. At the end of the refinement process, some sliver shaped tetrahedra may occur in the mesh. The optimization phase aims at eliminating slivers.

The criteria can be tuned to achieve the user needs with respect to the size of mesh elements, the accuracy of boundary approximation and topological conditions. The default criteria for surface facets are governed by the three following parameters:

- *the angular bound*: This parameter controls the shape of surface facets. Actually, it is a lower bound for the angle (in degree) of surface mesh facets. The termination of the meshing process is guaranteed if the angular bound is at most 30 degrees.
- *the radius bound*: This parameter controls the size (edge length) of surface facets. Actually, each surface facet has a surface Delaunay ball which is a ball circumscribing the surface facet and centered on the surface patch. The radius bound is an upper bound on the radii of surface Delaunay balls.
- *the distance bound*: This parameter controls the approximation error of the surface. Actually, it is an upper bound for the distance between the circumcenter of a surface facet and the center of a surface Delaunay ball of this facet.

The default criteria for mesh cells are governed by two parameters:

- *the radius-edge bound*: This parameter controls the shape of mesh cells (but can't filter slivers, as we discussed earlier). Actually, it is an upper bound for the ratio between the circumradius of a mesh tetrahedron and its shortest edge.
- *the radius bound*: This parameter controls the size (edge length) of mesh cells. Actually, it is an upper bound on the circumradii of the mesh tetrahedra.

Figure 49.2 shows how the mesh generation process behaves with respect to these parameters.

Optimization phase

The optimization phase is a succession of optimization processes, including possibly a Lloyd smoothing, an odt-smoothing, a perturber and an exuder.

The Lloyd and odt-smoother are global optimizers moving the mesh vertices to minimize a mesh energy. Those optimizers are described respectively in [DFG99, DW02] and in [Che04, ACSYD05]. In both case the mesh energy is the $L1$ error resulting from the interpolation of the function $f(x) = x^2$ by a piecewise linear function. In the case of Lloyd smoother, the interpolation is linear in each Voronoi cell of the set of mesh vertices. In the case

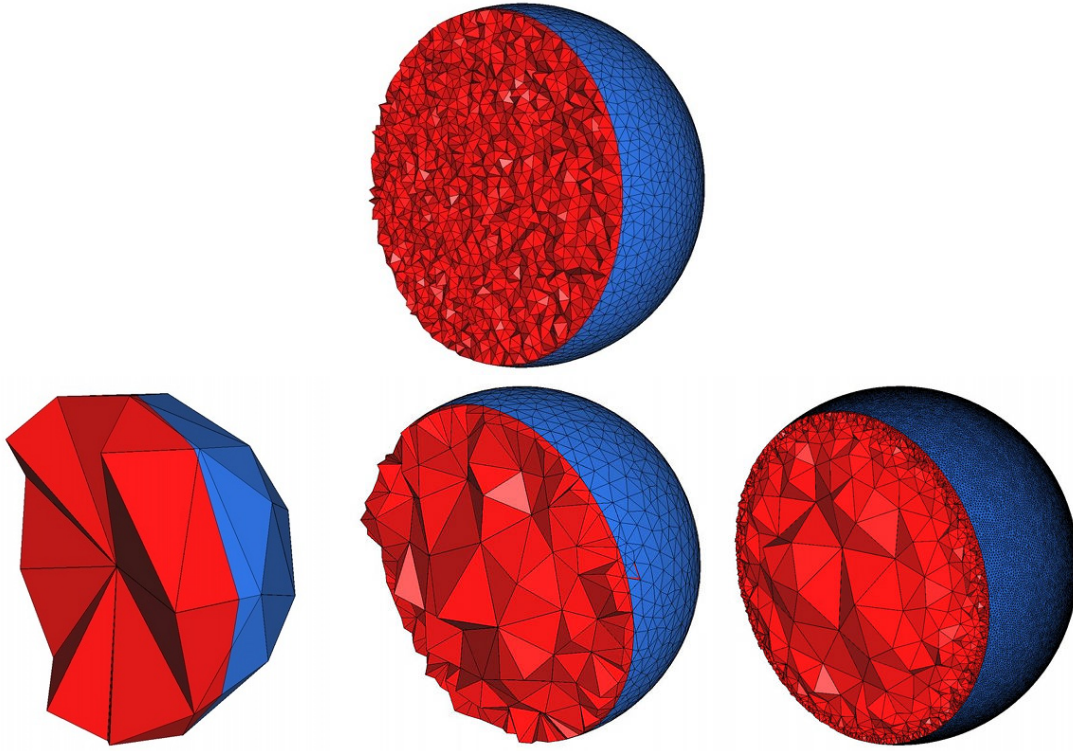

Figure 49.2: Top : the mesh is obtained using the parameters $(25, 0.15, 0.05)$ for the angular bound, radius bound and distance bound of surface facets and $(4, 0.2)$ for the radius-edge bound and radius bound of mesh cells. The result is a uniform mesh which contains tetrahedra of about the same size. Bottom left : the mesh is obtained by relaxing the *size bound* of tetrahedra and facets. The result is a small coarse mesh. Bottom middle : the mesh is obtained from the previous one by tightening the *distance bound* of surface facets to 0.01. The result is then a graded 3D mesh with a dense surface mesh achieving a precise approximation. Bottom right : the mesh is obtained from the previous one by fixing *radius bound* of surface facets to 0.01. The surface mesh is then denser to achieve the size bound.

of the odt-smoother, the interpolation is linear in each cell of the Delaunay triangulation of the mesh vertices, hence the name odt which is an abbreviation for “optimal Delaunay triangulation”. The Lloyd optimizer is known to be blind to the occurrence of slivers in the mesh while the odt-smoother tend to chase them out. Both of them are global optimizers, meaning that they try to improve the whole mesh rather than focusing on the worst elements. However, both are empirically known to be very efficient as a preliminary step of optimization, as they tend to enhance the efficiency of the perturber and/or exuder applied next.

The perturber and the exuder focus on improving the worst mesh elements. The perturber [TSA09] improves the meshes by local changes in the vertices positions aiming to make sliver disappear. The exuder [CDE⁺00] chases the remaining slivers by turning the Delaunay mesh into a weighted Delaunay mesh with optimal weights affected to the vertices.

Each optimization process can be activated or not, according to the user requirements and the available time. By default, only the perturber and the exuder are activated. For a maximum efficiency, whatever may be the optimization processes activated, they should be launched in the order that is a suborder of the following: *odt-smoother*, *Lloyd-smoother*, *perturber*, *exuder*. No smoother or perturber can be launched after an exudation process.

49.2 Interface

A 3D mesh generation process is launched through a call to one of the two following functions:

```
template <class C3T3, class MeshDomain, class MeshCriteria>
C3T3      make_mesh_3( MeshDomain domain,
                      MeshCriteria criteria,
                      parameters::internal::Lloyd lloyd = parameters::no_lloyd(),
                      parameters::internal::Odt odt = parameters::no_odt(),
                      parameters::internal::Perturb perturb = parameters::perturb(),
                      parameters::internal::Exude exude = parameters::exude())

template <class C3T3, class MeshDomain, class MeshCriteria>
void      refine_mesh_3( C3T3& c3t3,
                        MeshDomain domain,
                        MeshCriteria criteria,
                        parameters::internal::Lloyd lloyd = parameters::no_lloyd(),
                        parameters::internal::Odt odt = parameters::no_odt(),
                        parameters::internal::Perturb perturb = parameters::perturb(),
                        parameters::internal::Exude exude = parameters::exude())
```

The function *make_mesh_3* generates from scratch a mesh of the input domain, while the function *refine_mesh_3* refines an existing mesh of the input domain.

The template parameter *C3T3* is required to be a model of the concept *MeshComplex_3InTriangulation_3*, a data structure devised to represent a three dimensional complex embedded in a 3D triangulation. In both functions, an instance of type *C3T3* is used to maintain the current approximating simplicial mesh of the domain and subdomains and to represent the final 3D mesh at the end of the procedure. The type *C3T3* is required to provide a nested type *C3T3::Triangulation_3* for the 3D triangulation embedding the mesh. This triangulation is required to be a regular triangulation. The vertex and cell base classes of the triangulation *C3T3::Triangulation_3* are required to be respectively models of the concepts *MeshVertexBase_3* and *MeshCellBase_3*.

The template parameter *MeshDomain* is required to be a model of the concept *MeshDomain_3*. The argument *domain* of type *MeshDomain* is the sole link through which the domain to be discretized is known by the mesh generation algorithm. The concept *MeshDomain_3* is similar to the concept *SurfaceMeshTraits* defined by the surface mesh generation package. This concept provides, among others, member functions to test whether or not a query segment intersects boundary surfaces, and to compute an intersection point in the affirmative. The *MeshDomain_3* concept adds member functions which given a query point tell whether the point lies inside or outside the domain and in which subdomain the point lies if inside.

The template parameter *MeshCriteria* must be a model of the concepts *MeshCriteria_3*. The argument of type *MeshCriteria* passed to the mesh generator specifies the size and shape requirements for the tetrahedra in the mesh and for the triangles in the boundary surface mesh. These criteria condition the rules that drive the refinement process. At the end of the refinement process, mesh elements satisfy the criteria. This may not be strictly true anymore after the optimization phase, but this last phase is devised to only improve the mesh quality.

The four additional parameters are optimization parameters. They control which optimization processes are performed and allow the user to tune the parameters of the activated optimization processes. These parameters have internal types which are not described but the library provides two global functions for each, to generate appropriate values:

- `parameters::lloyd()` and `parameters::no_lloyd()` activate or deactivate the Lloyd smoother.
- `parameters::odt()` and `parameters::no_odt()` activate or deactivate the odt-smoother.
- `parameters::perturb()` and `parameters::no_perturb()` activate or deactivate the perturber.
- `parameters::exude()` and `parameters::no_exude()` activate or deactivate the exuder.

These parameters are optional and can be passed in any order. If one parameter is not passed the default value is used. By default, only the perturber and the exuder are activated. Note that whatever may be the optimization processes activated by `make_mesh_3` or `refine_mesh_3`, they are always launched in the order that is a suborder of the following: *odt smoother*, *Lloyd smoother*, *perturber* and *exuder*.

The package also provides four global functions to launch each optimization process independently. These functions are useful for advanced experimentation on the efficiency of each optimization method. Note however that the exuder adds on mesh vertices weights that are conditioned by vertices positions. Therefore an exudation process should never be run before a smoother or a perturber.

```
template< C3T3, MeshDomain>
Mesh_optimization_return_code    lloyd_optimize_mesh_3( C3T3& c3t3, MeshDomain domain)
```

```
template< C3T3, MeshDomain>
Mesh_optimization_return_code    odt_optimize_mesh_3( C3T3& c3t3, MeshDomain domain)
```

```
template< C3T3, MeshDomain>
Mesh_optimization_return_code    perturb_mesh_3( C3T3& c3t3, MeshDomain domain)
```

```
template< C3T3>
Mesh_optimization_return_code    exude_mesh_3( C3T3& c3t3)
```

49.3 Examples

49.3.1 Mesh Generation From an Implicit Domain

The following code produces a 3D mesh for a domain whose boundary surface is defined by an implicit function. Figure 49.3 shows a cut view of the resulting mesh.

```
#include <CGAL/Exact_predicates_inexact_constructions_kernel.h>

#include <CGAL/Mesh_triangulation_3.h>
#include <CGAL/Mesh_complex_3_in_triangulation_3.h>
#include <CGAL/Mesh_criteria_3.h>

#include <CGAL/Implicit_mesh_domain_3.h>
#include <CGAL/make_mesh_3.h>

// Domain
typedef CGAL::Exact_predicates_inexact_constructions_kernel K;
typedef K::FT FT;
typedef K::Point_3 Point;
typedef FT (Function) (const Point&);
```

```

typedef CGAL::Implicit_mesh_domain_3<Function,K> Mesh_domain;

// Triangulation
typedef CGAL::Mesh_triangulation_3<Mesh_domain>::type Tr;
typedef CGAL::Mesh_complex_3_in_triangulation_3<Tr> C3t3;

// Criteria
typedef CGAL::Mesh_criteria_3<Tr> Mesh_criteria;

// To avoid verbose function and named parameters call
using namespace CGAL::parameters;

// Function
FT sphere_function (const Point& p)
{ return CGAL::squared_distance(p, Point(CGAL::ORIGIN))-1; }

int main()
{
    // Domain (Warning: Sphere_3 constructor uses squared radius !)
    Mesh_domain domain(sphere_function, K::Sphere_3(CGAL::ORIGIN, 2.));

    // Mesh criteria
    Mesh_criteria criteria(facet_angle=30, facet_size=0.1,
        facet_distance=0.025,
                           cell_radius_edge=2, cell_size=0.1);

    // Mesh generation
    C3t3 c3t3 = CGAL::make_mesh_3<C3t3>(domain, criteria);

    // Output
    std::ofstream medif_file("out.mesh");
    c3t3.output_to_medif(medif_file);

    return 0;
}

```

49.3.2 Mesh Generation From a Polyhedral Domain

The following code produces a 3D mesh for a domain defined by polyhedral surfaces. Figure [49.4](#) shows the resulting mesh.

```

#include <CGAL/Exact_predicates_inexact_constructions_kernel.h>
#include <CGAL/Mesh_3/Robust_intersection_traits_3.h>

#include <CGAL/Mesh_triangulation_3.h>
#include <CGAL/Mesh_complex_3_in_triangulation_3.h>
#include <CGAL/Mesh_criteria_3.h>

#include <CGAL/Polyhedral_mesh_domain_3.h>

```

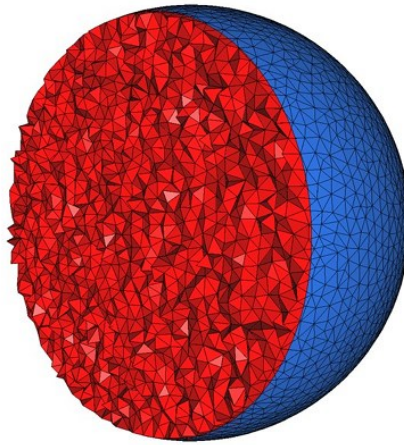

Figure 49.3: Cut-View of a 3D mesh produced from an implicit domain

```
#include <CGAL/make_mesh_3.h>
#include <CGAL/refine_mesh_3.h>

// IO
#include <CGAL/IO/Polyhedron_iostream.h>

// Domain
// (we use exact intersection computation with
//   Robust_intersection_traits_3)
typedef CGAL::Exact_predicates_inexact_constructions_kernel K;
typedef CGAL::Mesh_3::Robust_intersection_traits_3<K> Geom_traits;
typedef CGAL::Polyhedron_3<Geom_traits> Polyhedron;
typedef CGAL::Polyhedral_mesh_domain_3<Polyhedron, Geom_traits>
    Mesh_domain;

// Triangulation
typedef CGAL::Mesh_triangulation_3<Mesh_domain>::type Tr;
typedef CGAL::Mesh_complex_3_in_triangulation_3<Tr> C3t3;

// Criteria
typedef CGAL::Mesh_criteria_3<Tr> Mesh_criteria;

// To avoid verbose function and named parameters call
using namespace CGAL::parameters;

int main()
{
    // Create input polyhedron
    Polyhedron polyhedron;
    std::ifstream input("data/elephant.off");
    input >> polyhedron;

    // Create domain
    Mesh_domain domain(polyhedron);
```

```

// Mesh criteria (no cell_size set)
Mesh_criteria criteria(facet_angle=25, facet_size=0.15,
    facet_distance=0.008,
    cell_radius_edge=3);

// Mesh generation
C3t3 c3t3 = CGAL::make_mesh_3<C3t3>(domain, criteria, no_perturb(),
    no_exude());

// Output
std::ofstream medit_file("out_1.mesh");
c3t3.output_to_medit(medit_file);
medit_file.close();

// Set tetrahedron size (keep cell_radius_edge), ignore facets
Mesh_criteria new_criteria(cell_radius_edge=3, cell_size=0.03);

// Mesh refinement
CGAL::refine_mesh_3(c3t3, domain, new_criteria);

// Output
medit_file.open("out_2.mesh");
c3t3.output_to_medit(medit_file);

return 0;
}

```

File: examples/Mesh_3/mesh_polyhedral_domain.cpp

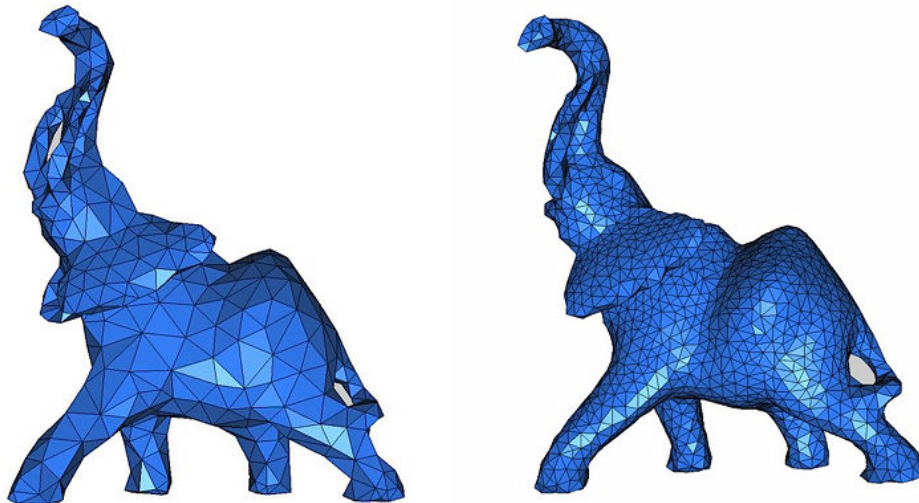

Figure 49.4: View of 3D meshes produced from a polyhedral domain. (i) is a view of file out_1.mesh and (ii) is a view of file out_2.mesh. Code from subsection [49.3.2](#) generates these files.

49.3.3 Mesh Generation From a Segmented 3D Image

The following code produces a 3D mesh from a 3D image. The image is a segmented medical image in which each voxel is associated a label in accordance with the tissue the voxel belongs to. The domain is therefore a multi-domain where each subdomain corresponds to a specific tissue. The resulting mesh is shown in Figure 49.5.

```
#include <CGAL/Exact_predicates_inexact_constructions_kernel.h>

#include <CGAL/Mesh_triangulation_3.h>
#include <CGAL/Mesh_complex_3_in_triangulation_3.h>
#include <CGAL/Mesh_criteria_3.h>

#include <CGAL/Labeled_image_mesh_domain_3.h>
#include <CGAL/make_mesh_3.h>
#include <CGAL/Image_3.h>

// Domain
typedef CGAL::Exact_predicates_inexact_constructions_kernel K;
typedef CGAL::Labeled_image_mesh_domain_3<CGAL::Image_3,K> Mesh_domain;

// Triangulation
typedef CGAL::Mesh_triangulation_3<Mesh_domain>::type Tr;
typedef CGAL::Mesh_complex_3_in_triangulation_3<Tr> C3t3;

// Criteria
typedef CGAL::Mesh_criteria_3<Tr> Mesh_criteria;

// To avoid verbose function and named parameters call
using namespace CGAL::parameters;

int main()
{
    // Loads image
    CGAL::Image_3 image;
    image.read("data/liver.inr.gz");

    // Domain
    Mesh_domain domain(image);

    // Mesh criteria
    Mesh_criteria criteria(facet_angle=30, facet_size=6, facet_distance=4,
                          cell_radius_edge=3, cell_size=8);

    // Meshing
    C3t3 c3t3 = CGAL::make_mesh_3<C3t3>(domain, criteria);

    // Output
    std::ofstream medit_file("out.mesh");
    c3t3.output_to_medit(medit_file);

    return 0;
}
```

File: examples/Mesh_3/mesh_3D_image.cpp

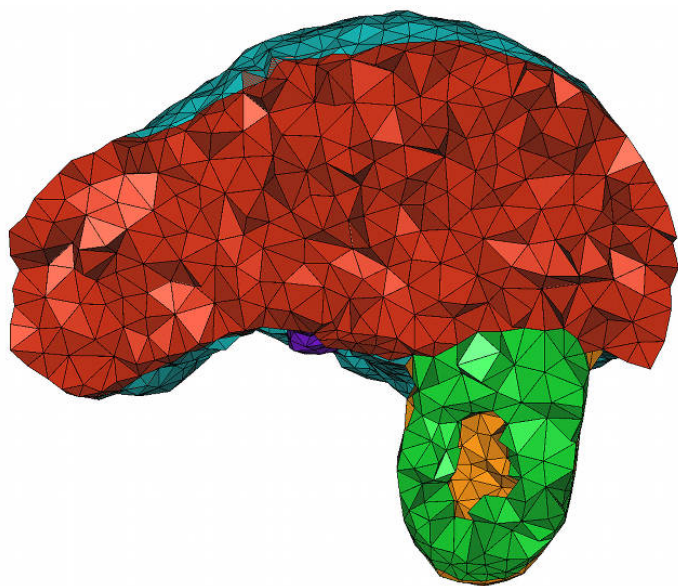

Figure 49.5: Cut-view of a 3D mesh produced from a segmented liver image. Code from subsection [49.3.3](#) generates this file.

49.3.4 Tuning mesh optimization

In the previous examples, the mesh generation is launched through a call `make_mesh_3(domain,criteria)` with a minimal number of parameters. In such cases, the default optimization strategy is applied: after the Delaunay refinement process two optimization steps are performed, a perturbation and a sliver exudation. The following examples show how to disable default optimization steps and how to tune the parameters of optimization steps.

Disabling exudation and tuning perturbation

In this first example, we show how to disable the exudation step. The optimization phase after the refinement includes only a perturbation phase which is launched with no time bound and an objective of 10 degrees for the minimum dihedral angle of the mesh. The example shows two ways of achieving the same result. The first way issues a single call to `make_mesh_3` with the required optimization process activated and tuned. In the second way, `make_mesh_3` is first called without any optimization process and the resulting mesh is next optimized through a call to `perturb_mesh_3` with tuned parameters.

```
#include <CGAL/Exact_predicates_inexact_constructions_kernel.h>

#include <CGAL/Mesh_triangulation_3.h>
#include <CGAL/Mesh_complex_3_in_triangulation_3.h>
#include <CGAL/Mesh_criteria_3.h>

#include <CGAL/Labeled_image_mesh_domain_3.h>
#include <CGAL/make_mesh_3.h>
#include <CGAL/Image_3.h>
```

```

// Domain
typedef CGAL::Exact_predicates_inexact_constructions_kernel K;
typedef CGAL::Labeled_image_mesh_domain_3<CGAL::Image_3,K> Mesh_domain;

// Triangulation
typedef CGAL::Mesh_triangulation_3<Mesh_domain>::type Tr;
typedef CGAL::Mesh_complex_3_in_triangulation_3<Tr> C3t3;

// Mesh Criteria
typedef CGAL::Mesh_criteria_3<Tr> Mesh_criteria;

// To avoid verbose function and named parameters call
using namespace CGAL::parameters;

int main()
{
    // Domain
    CGAL::Image_3 image;
    image.read("data/liver.inr.gz");
    Mesh_domain domain(image);

    // Mesh criteria
    Mesh_criteria criteria(facet_angle=30, facet_size=5,
        facet_distance=1.5,
                           cell_radius_edge=2, cell_size=7);

    // Mesh generation and optimization in one call
    C3t3 c3t3 = CGAL::make_mesh_3<C3t3>(domain, criteria,
                                         no_exude(),
                                         perturb(sliver_bound=10,
                                         time_limit=15));

    // Mesh generation and optimization in several call
    C3t3 c3t3_bis = CGAL::make_mesh_3<C3t3>(domain, criteria,
                                         no_perturb(), no_exude());

    CGAL::perturb_mesh_3(c3t3_bis, domain, time_limit=15, sliver_bound=10);

    // Output
    std::ofstream medit_file("out.mesh");
    c3t3.output_to_medit(medit_file);

    std::ofstream medit_file_bis("out_bis.mesh");
    c3t3_bis.output_to_medit(medit_file_bis);

    return 0;
}

```

File: examples/Mesh_3/mesh_optimization_example.cpp

Using Lloyd global optimization

In this second example, we show how to call the Lloyd optimization on the mesh, followed by a call to exudation. We set a time bound of 30s for the Lloyd optimization. We set a time bound of 10s for the exuder and a sliver bound of 10 degrees.

```
#include <CGAL/Exact_predicates_inexact_constructions_kernel.h>

#include <CGAL/Mesh_triangulation_3.h>
#include <CGAL/Mesh_complex_3_in_triangulation_3.h>
#include <CGAL/Mesh_criteria_3.h>

#include <CGAL/Labeled_image_mesh_domain_3.h>
#include <CGAL/make_mesh_3.h>
#include <CGAL/Image_3.h>

// Domain
typedef CGAL::Exact_predicates_inexact_constructions_kernel K;
typedef CGAL::Labeled_image_mesh_domain_3<CGAL::Image_3,K> Mesh_domain;

// Triangulation
typedef CGAL::Mesh_triangulation_3<Mesh_domain>::type Tr;
typedef CGAL::Mesh_complex_3_in_triangulation_3<Tr> C3t3;

// Mesh Criteria
typedef CGAL::Mesh_criteria_3<Tr> Mesh_criteria;

// To avoid verbose function and named parameters call
using namespace CGAL::parameters;

int main()
{
    // Domain
    CGAL::Image_3 image;
    image.read("data/liver.inr.gz");
    Mesh_domain domain(image);

    // Mesh criteria
    Mesh_criteria criteria(facet_angle=30, facet_distance=1.2,
                          cell_radius_edge=2);

    // Mesh generation and optimization in one call
    C3t3 c3t3 = CGAL::make_mesh_3<C3t3>(domain, criteria,
                                         lloyd(time_limit=30),
                                         no_perturb(),
                                         exude(time_limit=10,
                                               sliver_bound=10));

    // Mesh generation and optimization in several call
    C3t3 c3t3_bis = CGAL::make_mesh_3<C3t3>(domain, criteria,
                                             no_perturb(), no_exude());

    CGAL::lloyd_optimize_mesh_3(c3t3_bis, domain, time_limit=30);
    CGAL::exude_mesh_3(c3t3_bis, sliver_bound=10, time_limit=10);
}
```

```

// Output
std::ofstream medit_file("out.mesh");
c3t3.output_to_medit(medit_file);

std::ofstream medit_file_bis("out_bis.mesh");
c3t3_bis.output_to_medit(medit_file_bis);

return 0;
}

```

49.4 Performances

We provide some performance numbers about our mesh generation engine. The machine used is a PC running Linux64 with two Intel Xeon CPU X5450 clocked at 3.00 GHz with 32GB of RAM. The program has been compiled with g++ v4.3.2 with the -O3 option. Note that our implementation does not take advantage of multi-core architectures.

49.4.1 Delaunay refinement

We study the refinement part of the mesh generation engine in this section. We give CPU time (measured by *CGAL::Timer*) using the 3 provided oracles. In all experiments, we produce well shaped elements: we set facet angle bound and radius edge bound to their theoretical limit (resp. 30 degrees and 2). We also use the same size for facets and cells.

Implicit function

We mesh an analytical sphere of radius 1.

Size bound	vertices nb	facets nb	tetrahedra nb	CPU Time (s)
0.4	358	394	1,546	0.047
0.2	2,306	1,524	12,100	0.295
0.1	16,832	6,234	97,109	2.46
0.05	127,865	24,868	776,098	22.9
0.025	996,256	100,404	6,204,502	204

Polyhedral domain

We mesh a volume bounded by a close triangulated surface made of about 50,000 vertices and 100,000 triangles. Picture [49.6](#) shows the mesh obtained when size is set to 0.005.

Figure 49.6: View of polyhedral mesh generation result (size = 0.005).

Size bound	vertices nb	facets nb	tetrahedra nb	CPU Time (s)
0.04	397	674	1,262	0.339
0.02	2,697	3,547	11,177	2.70
0.01	18,176	15,578	90,480	19.7
0.005	129,377	64,793	721,355	152

3D image

We mesh image number 2 from the 3D-IRCADb-01¹ public database. The size of this image is 512x512x172 voxels (about 45M voxels). The size of the voxels is 0.78mm x 0.78mm x 1.6mm. Picture 49.7 shows the mesh obtained for size set to 4.

¹available at <http://www.ircad.fr/software/3Dircadb/3Dircadb1/index.php>

Figure 49.7: View of 3d image mesh generation result (size = 4).

Size bound (mm)	vertices nb	facets nb	tetrahedra nb	CPU Time (s)
16	3,743	3,735	19,886	0.880
8	27,459	19,109	159,120	6.97

49.5 Design and Implementation History

Work on the package *Mesh_3* started during the PhD thesis of Laurent Rineau advised by Mariette Yvinec. A first version of the specifications and code came out of their collaboration.

From the beginning of 2009, most of the work has been performed by Stéphane Tayeb, in collaboration with Mariette Yvinec, Laurent Rineau, Pierre Alliez and Jane Tournois. First, Stéphane released the first public version of the package, implementing the specifications written by Laurent and Mariette.

Since then, Stéphane added the optimization processes which are heavily based on the work of Jane Tournois and Pierre Alliez during the PhD of Jane advised by Pierre.

In collaboration with Laurent Rineau, Stéphane also added demos and examples.

BisectionGeometricTraits_3

Definition

The concept `BisectionGeometricTraits_3` describes a geometric traits class that provides the basic types and operations to implement a model of *MeshDomain_3* based solely on intersection detections. Points in the non-empty intersections are herein computed by bisection.

Such traits class is relevant when intersection detections can be performed efficiently. For instance, when bounding surfaces are implicitly described by a function (such as an isosurface of a 3D function from \mathbb{R}^3 to \mathbb{R}), the do-intersect predicate with a segment is computed by evaluations of the function values at both end points of the segment.

Types

BisectionGeometricTraits_3:: FT Numerical type. Must be a model of *SqrtFieldNumberType* and constructible from a *double*.

BisectionGeometricTraits_3:: Point_3 The point type. Must have a constructor *Point_3(FT, FT, FT)*.

BisectionGeometricTraits_3:: Segment_3 Segment type.

BisectionGeometricTraits_3:: Ray_3 Ray type.

BisectionGeometricTraits_3:: Line_3 Line type.

BisectionGeometricTraits_3:: Vector_3 Vector type.

BisectionGeometricTraits_3:: Sphere_3 Sphere type.

BisectionGeometricTraits_3:: Compute_scalar_product_3

Function object providing the operator
FT operator()(Vector_3 v, Vector_3 w) which returns the scalar (inner) product of the two vectors *v* and *w*.

BisectionGeometricTraits_3:: Compute_squared_distance_3

Function object providing the operator
FT operator()(Point_3, Point_3) which returns the squared distance between two points.

BisectionGeometricTraits_3:: Compute_squared_radius_3

Function object providing the operator
FT operator()(Sphere_3 s) which returns the squared radius of *s*.

BisectionGeometricTraits_3:: Construct_center_3

Function object providing the operator
Point_3 operator()(Sphere_3 s) which returns the center of the sphere *s*.

BisectionGeometricTraits_3:: Construct_midpoint_3

Function object providing the operator
Point_3 operator()(Point_3 p, Point_3 q) which computes the midpoint of the segment *pq*.

BisectionGeometricTraits_3:: Construct_point_on_3

Function object providing the following operators:
Point_3 operator()(Line_3 l,int i); which returns an arbitrary point on *l*. It holds *point(i) == point(j)*, iff *i==j*. Furthermore, is directed from *point(i)* to *point(j)*, for all *i < j*.
Point_3 operator()(Ray_3 r,int i); which returns a point on *r*. *point(0)* is the source, *point(i)*, with *i > 0*, is different from the source.
Precondition: i ≥ 0.
Point_3 operator()(Segment_3 s,int i); which returns either source or target of *s*: *point(0)* returns the source of *s*, *point(1)* returns the target of *s*. Parameter *i* is taken modulo 2, which gives easy access to the other end point.

BisectionGeometricTraits_3:: Construct_segment_3

Function object providing the operator
Segment_3 operator()(Point_3 p, Point_3 q); which returns a segment with source *p* and target *q*, directed from the source to the target.

BisectionGeometricTraits_3:: Construct_scaled_vector_3

Function object providing the operator
Vector_3 operator()(Vector_3 v, FT scale) which returns the vector *v* scaled by a factor *scale*.

BisectionGeometricTraits_3:: Construct_translated_point_3

Function object providing the operator
Point_3 operator()(Point_3 p, Vector_3 v) which returns the point obtained by translating *p* by the vector *v*.

BisectionGeometricTraits_3:: Construct_vector_3

Function object providing the operator
Vector_3 operator()(Point_3 a, Point_3 b) which returns the vector *b-a*.

BisectionGeometricTraits_3:: Has_on_bounded_side_3

Function object providing the operator
bool operator()(Sphere_3 s, Point_3 p); which returns true iff *p* lies on the bounded side of *s*.

Operations

The following functions give access to the predicate and construction objects:

<i>Compute_scalar_product_3</i>	<i>traits.compute_scalar_product_3_object()</i>
<i>Compute_squared_distance_3</i>	<i>traits.compute_squared_distance_3_object()</i>
<i>Compute_squared_radius_3</i>	<i>traits.compute_squared_radius_3_object()</i>
<i>Construct_center_3</i>	<i>traits.construct_center_3_object()</i>
<i>Construct_midpoint_3</i>	<i>traits.construct_midpoint_3_object()</i>
<i>Construct_point_on_3</i>	<i>traits.construct_point_on_3_object()</i>
<i>Construct_scaled_vector_3</i>	<i>traits.construct_scaled_vector_3_object()</i>
<i>Construct_segment_3</i>	<i>traits.construct_segment_3_object()</i>
<i>Construct_translated_point_3</i>	<i>traits.construct_translated_point_3_object()</i>
<i>Construct_vector_3</i>	<i>traits.construct_vector_3_object()</i>
<i>Has_on_bounded_side_3</i>	<i>traits.has_on_bounded_side_3_object()</i>

CGAL::exude_mesh_3

Definition

The function *exude_mesh_3* performs a sliver exudation process on a Delaunay mesh.

The sliver exudation process consists in turning the Delaunay triangulation into a weighted Delaunay triangulation and optimizing the weights of vertices in such a way that slivers disappear and the quality of the mesh improves.

```
#include <CGAL/exude_mesh_3.h>
```

```
template<typename C3T3>
```

```
Mesh_optimization_return_code
```

```
exude_mesh_3( C3T3& c3t3, double time_limit=0, double sliver_bound=0)
```

Precondition: $time_limit \geq 0$ and $0 \leq sliver_bound \leq 180$

Parameters

Parameter *C3T3* is required to be a model of the concept *MeshComplex_3InTriangulation_3*. The argument *c3t3*, passed by reference, provides the initial mesh and is modified by the algorithm to represent the final optimized mesh.

The function has two optional parameters which are named parameters (we use the Boost.Parameters library). Therefore, when calling the function, the parameters can be provided in any order provided that the names of the parameters are used (see example at the bottom of this page).

- Parameter *time_limit*, whose name is *parameters::time_limit*, is used to set up, in seconds, a CPU time limit after which the optimization process is stopped. This time is measured using the *CGAL::Timer* class. The default value is *0* and means that there is no time limit.
- Parameter *sliver_bound*, whose name is *parameters::sliver_bound*, is designed to give, in degree, a targeted lower bound on dihedral angles of mesh cells. The exudation process considers in turn all the mesh cells that have a smallest dihedral angle less than *sliver_bound* and tries to make them disappear by weighting their vertices. The optimization process stops when every cell in the mesh achieves this quality. The default value is *0* and means that there is no targeted bound : the exuder then runs as long as it can improve the smallest dihedral angles of the set of cells incident to some vertices.

Return Values

The function *exude_mesh_3* returns a value of type *Mesh_optimization_return_code* which is:

- *BOUND_REACHED* when the targeted bound for the smallest dihedral angle in the mesh is reached.
- *TIME_LIMIT_REACHED* when the time limit is reached.
- *CANT_IMPROVE_ANYMORE* when exudation process stops because it can no longer improve the smallest dihedral angle of the set of cells incident to some vertex in the mesh.

```

CGAL::Implicit_mesh_domain_3<Function,BGT>

Definition

The class *Implicit_mesh_domain_3<Function,BGT>* implements a domain whose bounding surface is described implicitly as the zero level set of a function. The domain to be discretized is assumed to be the domain where the function has negative values. This class is a model of the concept *MeshDomain_3*.

Parameters

Parameter *BGT* is a geometric traits which provides the basic operations to implement intersection tests and computations through a bisection method. This parameter must be instantiated with a model of the concept *BisectionGeometricTraits_3*.

Parameter *Function* provides the definition of the function. This parameter stands for a model of the concept *ImplicitFunction* described in the surface mesh generation package. The number types *Function::FT* and *BGT::FT* are required to match.

The constructor of *Implicit_mesh_domain_3<Function,BGT>* takes as argument a bounding sphere which is required to circumscribe the surface and to have its center inside the domain. This domain constructs intersection points between the surface and segments/rays/lines by bisection. It needs an *error_bound* such that the bisection process is stopped when the query segment is smaller than the error bound. The *error_bound* passed as argument to the domain constructor is a relative error bound expressed as a ratio to the bounding sphere radius.

```
#include <CGAL/Implicit_mesh_domain_3.h>
```

Is Model for the Concepts

MeshDomain_3

Creation

```
Implicit_mesh_domain_3<Function,BGT> domain( Function f,
                                             BGT::Sphere_3 bounding_sphere,
                                             BGT::FT error_bound = FT(1e-3))
```

f is the object of type *Function* that represents the implicit surface.

bounding_sphere is a bounding sphere of the implicit surface. The value of *f* at the sphere center *c* must be negative: $f(c) < 0$.

error_bound is the relative error bound used to compute intersection points between the implicit surface and query segments. The bisection is stopped when the length of the intersected segment is less than the product of *error_bound* by the radius of *bounding_sphere*.

IntersectionGeometricTraits_3

Definition

The concept `IntersectionGeometricTraits_3` provides types and functors required to implement a model of *MeshDomain_3*, when the domain is described by a simplicial surface mesh forming its boundary. The concept `IntersectionGeometricTraits_3` mainly provides the detection and construction of intersections between segments and triangles.

Types

IntersectionGeometricTraits_3::Point_3 Point type.
IntersectionGeometricTraits_3::Segment_3 Segment type.
IntersectionGeometricTraits_3::Triangle_3 Triangle type.

IntersectionGeometricTraits_3::Do_intersect_3

Function object that detects an intersection between a 3D segment and a 3D triangle. Provides the operators:
bool operator()(Segment_3 seg, Triangle_3 tr)
bool operator()(Triangle_3 tr, Segment_3 seg)
 which return *true*, iff the triangle and the segment have a non empty intersection.

IntersectionGeometricTraits_3::Intersect_3

Function object that constructs the intersection between a 3D segment and a 3D triangle. Provides the operators:
CGAL::Object operator()(Segment_3 seg, Triangle_3 tr)
CGAL::Object operator()(Triangle_3 tr, Segment_3 seg)
 which computes as a *CGAL::Object* the intersection between the triangle and the segment. *CGAL::Object* is either a point, a segment or an empty object.

Operations

Do_intersect_3 *traits.do_intersect_3_object()*

Returns the intersection detection functor.

Intersect_3 *traits.intersect_3_object()*

Returns the intersection constructor.

Has Models

Any instantiation of *CGAL::Kernel* is a model of this traits concept.

LabeledImage_3

Definition

The concept `LabeledImage_3` describes the requirements for the second template parameter of the class `Labeled_image_mesh_domain_3<Image,BGT>` which represents mesh domains defined by 3D labeled images. A 3D labeled image is a 3D array of elements of an integral type *Type*. *Type* can be *bool*, *char*, *short*, *int*, or *long* (signed or not). Such an array is associated to a 3D axis-aligned regular grid, in \mathbb{R}^3 . A cell of this grid is denoted by *voxel*. A voxel is an iso-cuboid of size *vx()*, *vy()*, and *vz()*.

Types

`LabeledImage_3::Type` Type of voxel data. Must be an integral type.

`LabeledImage_3::RT` Ring number type.

Operations

<i>int</i>	<code>image.xdim()</code>	First dimension of the 3D array, i.e., the number of voxels along the x coordinate axis.
<i>int</i>	<code>image.ydim()</code>	Second dimension of the 3D array.
<i>int</i>	<code>image.zdim()</code>	Third dimension of the 3D array.
<i>RT</i>	<code>image.vx()</code>	Size of each voxel along x coordinate axis.
<i>RT</i>	<code>image.vy()</code>	Size of each voxel along y coordinate axis.
<i>RT</i>	<code>image.vz()</code>	Size of each voxel along z coordinate axis.
<code>const Type*</code>	<code>image.data()</code>	Pointer to the first element of the 3D image. The size of the array must be <code>xdim()×ydim()×zdim()</code> .

Has Models

`CGAL::Image_3<Kernel, T>`, for any CGAL kernel *K* and any integral type *T*.

CGAL::Labeled_image_mesh_domain_3<Image,BGT>

Definition

The class *Labeled_image_mesh_domain_3<Image,BGT>* implements a domain described by a 3D labeled image. A 3D labeled image is a grid of voxels, where each voxel is associated with an index (a subdomain index) characterizing the subdomain in which the voxel lies. This class is a model of the concept *MeshDomain_3*. The domain to be discretized is the union of voxels that have a non-default index (different from the default constructed value of the type *Image::Type*).

This class includes a member function that provides, by interpolation, the subdomain index of any query point. An intersection between a segment and bounding surfaces is detected when both segment endpoints are associated with different values of subdomain indices. The intersection is then constructed by bisection. The bisection stops when the query segment is shorter than a given error bound e . This error bound is given by $e = d \times bound$ where d is the length of the diagonal of the bounding box (in world coordinates) and $bound$ is the argument passed to the constructor of *Labeled_image_mesh_domain_3<Image,BGT>*.

Parameters

Parameter *Image* is the type of the input image. This parameter must be a model of the concept *LabeledImage_3*.

Parameter *BGT* is a geometric traits class which provides the basic operations to implement intersection tests and intersection computations through a bisection method. This parameter must be instantiated with a model of the concept *BisectionGeometricTraits_3*.

```
#include <CGAL/Labeled_image_mesh_domain_3.h>
```

Is Model for the Concepts

MeshDomain_3

Creation

```
Labeled_image_mesh_domain_3<Image,BGT> domain( Image image, BGT::FT error_bound = FT(1e-3));
```

Construction from an image. The parameter *error_bound* is relative to the size of the image.

CGAL::lloyd_optimize_mesh_3

Definition

The function *lloyd_optimize_mesh_3* is a mesh optimization process based on the minimization of a global energy function.

In *lloyd_optimize_mesh_3*, the minimized global energy may be interpreted as the L^1 -norm of the error achieved when the function x^2 is interpolated on the mesh domain using a piecewise linear function which is linear in each cell of the Voronoi diagram of the mesh vertices.

The optimizer *lloyd_optimize_mesh_3* works in iterative steps. At each iteration, mesh vertices are moved into positions that bring to zero the energy gradient and the Delaunay triangulation is updated. Vertices on the mesh boundaries are handled in a special way so as to preserve an accurate representation of the domain boundaries.

```
#include <CGAL/lloyd_optimize_mesh_3.h>
```

```
template<typename C3T3, typename MeshDomain>
Mesh_optimization_return_code
```

```
    lloyd_optimize_mesh_3( C3T3& c3t3,
                          MeshDomain domain,
                          double time_limit=0,
                          std::size_t max_iteration_number=0,
                          double convergence=0.02,
                          double freeze_bound = 0.01)
```

Precondition: $time_limit \geq 0$ and $0 \leq convergence \leq 1$ and $0 \leq freeze_bound \leq 1$

Parameters

Parameter *C3T3* is required to be a model of the concept *MeshComplex_3InTriangulation_3*. The argument *c3t3*, passed by reference, provides the initial mesh and is modified by the algorithm to represent the final optimized mesh.

The function has four optional parameters which are named parameters (we use the Boost.Parameters library). Therefore, when calling the function, the parameters can be provided in any order provided that the names of the parameters are used (see example at the bottom of this page).

- Parameter *time_limit*, whose name is *parameters::time_limit*, is used to set up, in seconds, a CPU time limit after which the optimization process is stopped. This time is measured using *CGAL::Timer*. The default value is 0 and means that there is no time limit.
- Parameter *max_iteration_number*, whose name is *parameters::max_iteration_number*, sets a limit on the number of performed iterations. The default value of 0 means that there is no limit on the number of performed iterations.
- Parameter *convergence*, whose name is *parameters::convergence*, is a stopping criterion based on convergence: the optimization process is stopped, when at the last iteration, the displacement of any vertex is less than a given percentage of the length of the shortest edge incident to that vertex. The parameter *convergence* gives the threshold ratio.

- Parameter *freeze_bound*, whose name is *parameters::freeze_bound*, is designed to reduce running time of each optimization iteration. Any vertex that has a displacement less than a given percentage of the length of its shortest incident edge, is frozen (i.e. is not relocated). The parameter *freeze_bound* gives the threshold ratio. At each iteration, any vertex that moves, unfreezes all its incident vertices.

Return Values

The function *lloyd_optimize_mesh_3* returns a value of type *Mesh_optimization_return_code* which is:

- *TIME_LIMIT_REACHED* when the time limit is reached.
- *MAX_ITERATION_NUMBER_REACHED* when *lloyd_optimize_mesh_3* stops because it has performed *max_iteration_number* iterations.
- *CONVERGENCE_REACHED* when *lloyd_optimize_mesh_3* stops because the convergence criterion is achieved.

                      parameters::freeze_bound=0.001);
```

CGAL::make_mesh_3

Definition

The function *make_mesh_3* is a 3D mesh generator. It produces simplicial meshes which discretize 3D domains.

The mesh generation algorithm is a Delaunay refinement process followed by an optimization phase. The criteria driving the Delaunay refinement process may be tuned to achieve the user needs with respect to the size of mesh elements, the accuracy of boundaries approximation, etc.

The optimization phase is a sequence of optimization processes, including possibly a Lloyd smoothing, an odt-smoothing, a perturber and an exuder. Each optimization process can be activated or not, according to the user requirements and available time. By default, only the perturber and the exuder are activated. Note that the benefits of the exuder will be lost if the mesh is further refined afterwards.

The function outputs the mesh to an object which provides iterators to traverse the resulting mesh data structure or can be written to a file (see [49.3](#)).

```
template <class C3T3, class MeshDomain, class MeshCriteria>
C3T3      make_mesh_3( MeshDomain domain,
                      MeshCriteria criteria,
                      parameters::internal::Lloyd lloyd = parameters::no_lloyd(),
                      parameters::internal::Odt odt = parameters::no_odt(),
                      parameters::internal::Perturb perturb = parameters::perturb(),
                      parameters::internal::Exude exude = parameters::exude())
```

Parameters

Parameter *C3T3* is required to be a model of the concept *MeshComplex_3InTriangulation_3*. This is the return type.

The type *C3T3* is in particular required to provide a nested type *C3T3::Triangulation* for the 3D triangulation embedding the mesh. The vertex and cell base classes of the triangulation *C3T3::Triangulation* are required to be models of the concepts *MeshVertexBase_3* and *MeshCellBase_3* respectively.

Template parameter *MeshDomain* is required to be a model of the concept *MeshDomain_3*. The argument *domain* of type *MeshDomain* is the link through which the domain to be discretized is known by the mesh generation algorithm.

The argument of type *MeshCriteria* passed to the mesh generator specifies the size and shape requirements for the mesh tetrahedra and for the triangles in the boundary mesh facets. These criteria form the rules which drive the refinement process. All mesh elements satisfy those criteria at the end of the refinement process. The template parameter *MeshCriteria* has to be a model of the concept *MeshCriteria_3*.

The four additional parameters are optimization parameters. They control which optimization processes are performed and allow the user to tune the parameters of the optimization processes. We do not describe the types of optimization parameters as they are internal types. The package defines two global functions for each optimization parameter to generate appropriate value of this parameter.

- *parameters::lloyd()* and *parameters::no_lloyd()* are designed to trigger or not a call to *lloyd_optimize_mesh_3* function and to set the parameters of this optimizer. If one parameter is not set, the default value of *lloyd_optimize_mesh_3* is used for this parameter.
- *parameters::odt()* and *parameters::no_odt()* are designed to trigger or not a call to *odt_optimize_mesh_3* function and to set the parameters of this optimizer. If one parameter is not set, the default value of *odt_optimize_mesh_3* is used for this parameter.
- *parameters::perturb()* and *parameters::no_perturb()* are designed to trigger or not a call to *perturb_mesh_3* function and to set the parameters of this optimizer. If one parameter is not set, the default value of *perturb_mesh_3* is used for this parameter, except for the time bound which is set to be equal to the refinement cpu time.
- *parameters::exude()* and *parameters::no_exude()* are designed to trigger or not a call to *exude_mesh_3* function and to override to set the parameters of this optimizer. If one parameter is not set, the default value of *exude_mesh_3* is used for this parameter, except for the time bound which is set to be equal to the refinement cpu time.

The optimization parameters can be passed in random order. If one parameter is not passed, its default value is used. The default values are *no_lloyd()*, *no_odt()*, *perturb()* and *exude()*.

Note that whatever may be the optimization processes activated, they are always launched in the order that is a suborder of the following (see user manual for further details): *lloyd*, *odt*, *perturb*, *exude*.

MeshCellBase_3

Definition

The concept `MeshCellBase_3` describes the requirements for the *Cell* type of the triangulation used in the 3D mesh generation process. The type `MeshCellBase_3` refines the concept *RegularTriangulationCellBase_3*. As a CGAL 3D triangulation triangulates the whole convex hull of its vertices, it is needed to specify whether a given cell of the triangulation is inside the domain or not and which subdomain it belongs to in case of a multi-domain.

Moreover, this concept adds four markers per cell to mark the facets of the triangulation that are surface facets, and four additional helper markers used in some operations to mark for instance the facets that have been visited.

This concept also provides storage for the centers of Delaunay surface balls. Each surface facet has a Delaunay surface ball, i. e. a circumscribing ball, centered on an input complex surface patch, and empty of triangulation vertices. In the following we call *surface center* of a surface facet, the center of its biggest Delaunay surface ball.

RegularTriangulationCellBase_3

Types

<i>MeshCellBase_3:: Point</i>	Point type, required to match the point type of the 3D triangulation in which the mesh is embedded.
<i>MeshCellBase_3:: Subdomain_index;</i>	Type of indices for cells of the input complex. Must match the type <i>MeshDomain_3::Subdomain_index</i> .
<i>MeshCellBase_3:: Surface_index;</i>	Type of indices for surface patches of the input complex. Must match the type <i>MeshDomain_3::Surface_index</i> .

Operations

<i>Subdomain_index</i>	<i>cell.subdomain_index()</i>	Returns the index of the input subdomain that contains the cell <i>cell</i> of the triangulation.
<i>void</i>	<i>cell.set_subdomain_index(Subdomain_index index)</i>	Sets the subdomain index of the cell.
<i>bool</i>	<i>cell.is_facet_on_surface(int i)</i>	returns <i>true</i> iff <i>facet(i)</i> is a surface facet.

<i>void</i>	<i>cell.set_facet_on_surface(int i, Surface_index index)</i>	Sets <i>facet(i)</i> as a surface facet iff <i>index</i> is different from <i>Surface_index</i> default value.
